Abstract

Background: In Her2-positive advanced breast cancer, the upfront use of trastuzumab is well established. Upon progression on first-line therapy, patients may be switched to lapatinib. Others however remain candidates for continued antibody treatment (treatment beyond progression). Here, we aimed to identify factors predicting for activity of second-line trastuzumab-based therapy.

Methods: Ninety-seven patients treated with > 1 line of trastuzumab-containing therapy were available for this analysis. Her2-status was determined by immunohistochemistry and re-analyzed by FISH if a score of 2+ was gained. Time to progression (TTP) on second-line therapy was defined as primary study endpoint. TTP and overall survival (OS) were estimated using the Kaplan-Meier product limit method. Multivariate analyses (Cox proportional hazards model, multinomial logistic regression) were applied in order to identify factors associated with TTP, response, OS, and incidence of brain metastases. p values < 0.05 were considered to indicate statistical significance.

Results: Median TTP on second-line trastuzumab-based therapy was 7 months (95% CI 5.74-8.26), and 8 months (95% CI 6.25-9.74) on first-line, respectively (n.s.). In the multivariate models, none of the clinical or histopathological features could reliably predict for activity of second-line trastuzumab-based treatment. OS was 43 months suggesting improved survival in patients treated with trastuzumab in multiple-lines. A significant deterioration of cardiac function was observed in three patients; 40.2% developed brain metastases while on second-line trastuzumab or thereafter.

Conclusion: Trastuzumab beyond progression showed considerable activity. None of the variables investigated correlated with activity of second-line therapy. In order to predict for activity of second-line trastuzumab, it appears necessary to evaluate factors known to confer trastuzumab-resistance.

Background
Human epidermal growth factor receptor (Her) 2 (c-erbB2) is a member of the Her-family of transmembrane receptor proteins [1]. As no ligand has been identified, Her2 is believed to act mainly via amplification of signals from other members of the Her-family (EGFR, Her3, Her4) by forming heterodimers [2]. Key proteins involved in Her2 signal-transduction include phosphatidyl-inositol (PI) 3 kinase and the ras/raf cascade. Ultimately, activation of those signalling pathways results in changes of growth, differentiation, adhesion, apoptosis and angiogenesis [3]. Her2 is overexpressed in approximately 15 - 20% of breast cancer cases, and several studies have shown that this confers a more aggressive course of disease [4,5].

Trastuzumab (rhMab4D5) is a recombinant monoclonal humanized antibody targeting the extracellular domain of Her2. Different mechanisms of action have been suggested. Trastuzumab inhibits downstream signalling pathways and blocks the shedding of Her2's extracellular domain. It causes internalization and degradation of the Her2 receptor protein, cell cycle arrest due to decreased cyclin-dependent kinase-2 (CDK2) activity via p27 induction, and inhibition of DNA repair. Antibody dependent cellular cytotoxicity (ADCC) apparently also plays a role [6,7]. In addition, trastuzumab may sensitize tumour cells to the cytotoxic effects of conventional chemotherapy [8].

Phase II clinical trials established the activity of trastuzumab as single-agent in Her2-positive metastatic breast cancer [9,10]. Randomized studies proved the combination of trastuzumab and taxanes superior in terms of response, progression-free and overall survival over chemotherapy alone [11,12]. Accordingly, trastuzumab was approved as first-line treatment of Her2-positive metastatic breast cancer in combination with taxanes. However, primary resistance may occur and many tumours who have initial response to trastuzumab will acquire secondary resistance within one year. Trastuzumab resistance is likely multi-factorial, and no clinical surrogate is yet available [7].

Upon progression on trastuzumab-based first-line treatment, two options exist. Patients may be switched to lapatinib, a tyrosine-kinase inhibitor of EGFR and Her2, alternatively they may continue on trastuzumab in combination with capecitabine. Up until recently the latter approach was supported by data from retrospective analyses, prospective observations, and a small phase II trial only [13-15], while other studies questioned the potential benefit of treatment beyond progression [16]. In the meantime, a randomized phase III study reported results, suggesting that trastuzumab in combination with capecitabine is more active than chemotherapy alone upon progression on trastuzumab-based first-line treatment in terms of response rate and progression-free survival [17]. In contrast, in a large randomized phase III study, lapatinib plus capecitabine was active upon trastuzumab failure, and patients on lapatinib had a significantly lower incidence of brain metastases [18].

As of now, there are no means to prospectively define the optimal treatment approach for the individual patient. Therefore, we aimed to identify factors predicting for efficacy of trastuzumab treatment beyond disease progression. Furthermore, we tried to identify characteristics associated with early development of brain metastases, as this population will potentially benefit most from lapatinib.

Methods
All patient data were collected at the Department of Medicine 1 and Cancer Centre, Clinical Division of Oncology, at the Medical University of Vienna, Vienna, Austria. This retrospective analysis was performed in accordance with the ethical regulations of the Medical University of Vienna.

Patients
Ninety-seven consecutive patients treated from 2001 until 2008 with a minimum of two lines of trastuzumab-based therapy for metastatic disease were available for this analysis. All patients were suffering from histologically confirmed Her2-positive advanced breast cancer as defined per immunohistochemistry (IHC 3+) or fluorescence in-situ hybridization (FISH +). For baseline staging evaluations all patients had CT-scan of the chest and abdomen, mammography, and gynaecologic examination. Before initiation of trastuzumab treatment, echocardiography was mandatory, and patients with left ventricular ejection fraction (LVEF) below 50% were excluded.
Treatment plan and patient evaluation
Trastuzumab was administered at a dose of 8 mg/kg body weight loading dose on the first day of treatment, followed by 6 mg/kg body weight every three weeks thereafter [19]. Re-evaluation of patients’ tumour status was performed every three cycles of treatment with CT-scan of the chest and abdomen with additional work up if indicated. Echocardiography was repeated every 6 months or immediately if symptoms of congestive heart failure occurred. If a significant LVEF drop (> 10%) was observed but LVEF remained > 50%, those intervals were shortened to every 4 weeks according to our institution standards [20].

Statistical analysis
Time to disease progression (TTP) on the second trastuzumab-based regimen for metastatic disease was defined as primary study endpoint. Secondary endpoints consisted of response rate, time to progression on first-line trastuzumab-based therapy, cardiac toxicity, incidence of brain metastases, and overall survival (OS). TTP was defined as the interval from the first day of treatment until documented tumour progression. If a patient died without proper restaging, TTP was measured to the first day of clinical deterioration. OS was defined as the interval from the first day of trastuzumab application until death of any cause.

According to UICC criteria, complete response (CR) was defined as disappearance of all measurable lesions for a minimum of eight weeks. Partial response (PR) was defined as 25% or more reduction in sum of products of the greatest diameters of measurable lesions, no increase of lesion size and no new lesions. Stable disease (SD) was defined as less than 25% decrease and less than 25% increase without the appearance of new lesions. Progressive disease (PD) was defined as greater than 25% increase in tumour size or the appearance of new lesions.

TTP and OS were estimated using the Kaplan-Meier product-limit method. To test for differences between TTP curves, the log-rank test was used. p values less than 0.05 were considered to indicate statistical significance. In the univariate analysis of TTP, the following variables were included: age > 65 years; age < 35 years; tumour stage at primary diagnosis (localized versus metastatic); grading (1,2 versus 3); histological subtype (ductal versus lobular carcinoma); hormone receptor status (oestrogen and/or progesterone receptor positive versus negative); metastatic sites (non-visceral only versus visceral involvement); number of metastatic sites (1 versus ≥ 2; ≤ 2 versus > 2); time to disease recurrence < 12 months following primary treatment; trastuzumab from diagnosis of metastatic disease; response (CR + PR) to first-line trastuzumab treatment; and appearance of new metastatic sites upon progression on first-line trastuzumab. In the analysis of factors predicting for OS, development of brain metastases as well as early development of brain metastases (< 12 months after initiation of trastuzumab) were also included. A Cox proportional hazard model was applied as multivariate analysis to evaluate factors associated with OS and TTP on second-line trastuzumab-based therapy. Variables exhibiting significance (p < 0.05) or near significance (p < 0.08) at univariate analysis were included into the Cox regression models. To evaluate variables associated with treatment response to second-line trastuzumab-based therapy as well as development of brain metastases, a multinomial logistic regression model was used.

All statistics were calculated using statistical package for the social sciences (SPSS®) 16.0 software (SPSS Inc., Chicago, IL, USA). Data were analyzed as of February 2009.

Results
Patient characteristics
Ninety-seven consecutive patients, all female, suffering from Her2-positive metastatic breast cancer were identified from a breast cancer database. Median age was 51 years, range 25-78 years. Table 1 lists the characteristics of all patients included. 83.5% had invasive ductal carcinoma; 42.3% had positive hormone receptor status, and 66% grade 3 tumours. Sixty-seven patients (69.1%) were treated with adjuvant chemotherapy. Adjuvant endocrine therapy was administered in 26 patients (26.8%), and a further 9.3% received adjuvant trastuzumab for a median duration of 10 months (range 4-24 months). Twenty-four patients (24.7%) had metastatic disease at the time of primary diagnosis. Median time to disease recurrence in the reminders was 24.5 months (range 4-210 months). In 75.3%, visceral metastases were present upon initiation of palliative trastuzumab.

36.8% had received prior non-trastuzumab-containing therapy for metastatic disease, and 14.4% were switched to lapatinib after a median of four (range 2-9 lines) trastuzumab-based treatment lines.

Response and survival data
Follow-up data is available on all but one patient. Median time of observation was 24 months (range 8-84 months). Median TTP (second-line trastuzumab-based therapy) was 7 months (95% CI 5.74-8.26), and 8 months (95% CI 6.25-9.74) on first-line trastuzumab-based therapy respectively (n.s.). Clinical benefit rate (CBR) in the second-line setting was 66% (CR 7.2%, PR 23.7%, SD > 6 months 35.1%), as compared to CBR 83.5% (CR 9.3%, PR 35.1%, SD > 6 months 39.2%) on first-line. Efficacy endpoints are summarized in Table 2.
Patients with more than one metastatic site (TTP median 6 months [95% CI 5.06-6.98] versus 14 months [95% CI 9.56-18.44]; p = 0.013) as well as those with more than two metastatic sites (TTP median 6 months [95% CI 5.09-6.91] versus 8 months [95% CI 5.58-10.42]; p = 0.003) exhibited a significantly shorter time to disease progression (Table 3). Therefore, one versus more than one metastatic site appeared superior in prediction for TTP on second-line trastuzumab-based therapy and was included into the multivariate model. Furthermore, patients younger than 35 years derived less benefit from a second trastuzumab-based treatment line (TTP median 3 months [95% CI 0.23-5.77] versus 7 [95% CI 5.67-8.33]; 0.026) (Table 3). In the multivariate model however, only one versus more than one metastatic site was significantly associated with TTP (p = 0.037, OR 1.91, 95% CI 0.25-1.12) (Table 4).

None of the variables could independently predict for response to second-line trastuzumab-based therapy in the multinomial logistic regression model (Table 5).

One patient had brain metastases before initiation of antibody therapy, and thirty-nine (40.2%) developed brain metastases either on second-line treatment or thereafter. Median time to development of brain metastases was 21 months (95% CI 13.86-28.14), and overall survival following local treatment for brain metastases was 10 months (95% CI 4.53-15.47).

Twelve patients (30.8%) developed brain metastases in less than one year. In this subgroup, early development of brain metastases was significantly associated with the presence of visceral metastases in a multinomial logistic regression model (p = 0.012).
OS in the entire population was 43 months (95% CI 37.92-48.09) (Figure 1). In the univariate analyses (log-rank test), the following variables were significantly or near significantly associated with shorter OS: Age younger than 35 years (p = 0.023), hormone receptor negative disease (p = 0.075), more than one metastatic site (p = 0.003), more than two metastatic sites (p = 0.010), development of brain metastases (p = 0.010) as well as early development of brain metastases (p < 0.001) (Table 6). In the Cox regression model, only early development of brain metastases (p = 0.001) retained significance (Table 7).

Cardiac Toxicity
As outlined above, echocardiography was performed every six months longest, with shorter intervals if indicated. A significant drop in LVEF was observed in three patients (3.1%); in one patient, trastuzumab had to be stopped temporarily and in another discontinued permanently due to symptomatic congestive heart failure (Table 2).

In none of the patients switched to lapatinib, a significant drop in LVEF or congestive heart failure was observed.

**Discussion**
Concerning further therapy upon progression on trastuzumab-based first-line treatment, two options are available: Continuation of trastuzumab plus capecitabine, or a switch to the tyrosine kinase inhibitor lapatinib, again in combination with capecitabine. Both strategies are supported by data from prospective randomized phase III trials [17,18], although a continuation of trastuzumab is potentially less well established, as the trial conducted by the German Breast Group (GBG-26) had to be closed early due to poor accrual [17]. Still, given those results as well

### Table 2: Efficacy endpoints

| Endpoint                                                                                                                                                  | Results                                      |

as data from a number of smaller studies, it is safe to assume that there is a benefit from trastuzumab beyond progression in a subset of patients. Therefore, identifying this group in order to optimize palliative treatment for the individual patient is important.

Our retrospective data again suggest that continuation of trastuzumab is a valuable salvage option for patients with advanced Her2-positive breast cancer, whose disease has progressed on prior trastuzumab-based regimens. TTP on trastuzumab-based second-line treatment was 7 months

| Table 3: Univariate analysis: Influence on TTP (second-line) |
|------------------------------------------------------------|
| Factor | Median TTP (months) | 95% CI | SE* | p = |
| Age > 65 years | 6 vs. 7 | 0.00-12.79 | 3.36 | n.s. |
| Age < 35 years | 3 vs. 7 | 0.23-5.77 | 1.41 | 0.026 |
| Stage 4 at diagnosis | 6 vs. 7 | 5.52-8.48 | 0.76 | n.s. |
| Grading (1,2 versus 3) | 6 vs. 7 | 2.98-9.03 | 1.54 | n.s. |
| Histologic type (ductal versus lobular) | 6 vs. 9 | 4.86-7.14 | 0.58 | n.s. |
| Positive hormone receptor status | 6 vs. 7 | 4.64-7.36 | 0.7 | n.s. |
| Time to recurrence < 12 months | 6 vs. 7 | 3.41-8.59 | 1.32 | n.s. |
| Visceral metastases | 7 vs. 6 | 5.76-8.25 | 0.64 | n.s. |
| Number of metastatic sites (1 versus 2) | 14 vs. 6 | 9.56-18.44 | 2.26 | 0.013 |
| Number of metastatic sites (2 versus > 2) | 8 vs. 6 | 5.58-10.42 | 1.23 | 0.003 |
| Trastuzumab from first-line palliative treatment | 7 vs. 6 | 5.62-8.38 | 0.71 | n.s. |
| Response to first-line trastuzumab-based therapy | 7 vs. 6 | 5.25-8.75 | 0.89 | n.s. |
| New metastatic sites at progression upon first-line trastuzumab-based therapy | 7 vs. 6 | 4.81-9.19 | 1.12 | n.s. |

| Factor | p = | OR* | 95% CI |
| Age < 35 years | 0.097 | 0.53 | 1.04-3.5 |
| Number of metastatic sites (1 versus 2) | 0.037 | 1.91 | 0.25-1.12 |

* OR: Odds ratio
median, and therefore not significantly different from the
first-line setting. Those data are well in line with results
from different other studies as well as the single phase III
trial. In those studies, a TTP of 6 - 8 months on second-
line trastuzumab-based therapy was reported [13-17].

OS in our population was 43 months. This is considerably
longer than survival reported in the pivotal trastuzumab
plus taxane trials [11,12], and might even hint at a sur-
vival-benefit associated with the use of trastuzumab in
multiple lines. Still, as this is a retrospective analysis, data
need to be interpreted with caution: Only patients who
had at least two lines of trastuzumab-based therapy were
included. Outcome for patients with rapid progression,
not eligible for second-line trastuzumab-based treatment,
therefore is not reported. This potential bias might well
add to the magnitude of the observed survival advantage.

Our study was initiated in order to identify readily availa-
ble clinical or histopathological factors potentially pre-
dicting for activity of trastuzumab treatment beyond
progression. Furthermore, we tried to establish risk factors
for early development of brain metastasis, as this sub-
group might derive the largest benefit from lapatinib due
to the fact that tyrosine-kinase inhibitors may pass an
intact blood-brain-barrier. In the trial conducted by Geyer
et al, this assumption was proven correct by the signifi-
cantly lower number of brain metastases observed in the
lapatinib group [18].

In the Cox regression model, only the number of meta-
static sites (one versus more than one) was significantly
associated with time to disease progression on second-
line trastuzumab-based therapy. Trastuzumab therefore
seemed to have higher activity in patients with a low
number of metastases. While this could indicate a higher
responsiveness of certain tumours to trastuzumab, it is
rather possible that this result would have been observed
with lapatinib or chemotherapy alone as well. In the
multinomial logistic regression model none of the factors
analysed predicted for response to second-line trastuzu-
mbased therapy.

Therefore, readily available clinical and histopathological
features are not sufficient as decision-making tool, and
further exploration of mechanisms of resistance against
trastuzumab is warranted. Patients should be tested for
truncated Her2, as trastuzumab cannot bind to Her2-mol-
ecules lacking the extracellular domain [7]. Furthermore,
two recently presented studies suggested that tumours
with PTEN-loss and activated PI3-Kinase pathway may
be less responsive to trastuzumab [21,22].

### Table 5: Multinomial logistic regression model: Prediction of Response (second-line)

| Factor                                           | p    | OR   | 95% CI | p     |
|--------------------------------------------------|------|------|--------|-------|
| Age > 65 years                                   | 0.392| 0.35 | 0.03-3.9|
| Age < 35 years                                   | 0.363| 0.3  | 0.02-4  |
| Stage 4 at diagnosis                             | 0.839| 1.11 | 0.4-3.14|
| Grading (1,2 versus 3)                           | 0.268| 0.37 | 0.06-2.15|
| Histologic type (ductal versus lobular)          | 0.19 | 0.17 | 0.01-2.41|
| Positive hormone receptor status                 | 0.534| 0.63 | 0.15-2.68|
| Time to recurrence < 12 months                   | 0.332| 0.43 | 0.08-2.36|
| Visceral metastases                              | 0.147| 3.96 | 0.62-25-35|
| Number of metastatic sites (1 versus 2)          | 0.318| 0.36 | 0.05-2.64|
| Number of metastatic sites (2 versus > 2)        | 0.792| 0.82 | 0.18-3.63|
| Trastuzumab from first-line palliative treatment | 0.886| 1.15 | 0.18-7.53|
| Response to first-line trastuzumab-based therapy | 0.201| 2.58 | 0.6-11-08|
| New metastatic sites at progression upon first-line trastuzumab-based therapy | 0.953| 1.04 | 0.28-3.84|
As for overall survival, early development of brain metastases predicted for inferior outcome. In a logistic regression model, development of brain metastases in less than 12 months was significantly associated with presence of visceral metastases. This however is a feature of most Her2-positive tumours, therefore, this subgroup awaits further specification.

**Conclusion**

In conclusion, this retrospective analysis indicates that trastuzumab has increased overall survival in Her2-positive patients. Furthermore, those results again suggest that

### Table 6: Univariate analysis: Influence on OS

| Factor                                      | Median TTP (months) | 95% CI      | SE | p    |
|---------------------------------------------|--------------------|-------------|----|------|
| Age > 65 years                              | 44 vs. 43          | 29.77-58.23| 7.26| n.s. |

| Early development of brain metastases       | 19 vs. 44          | 9.11-28.89 | 2  | < 0.001|
|                                             |                    | 40.07-47.93| 5.05|      |

* NR: Median OS not reached

As for overall survival, early development of brain metastases predicted for inferior outcome. In a logistic regression model, development of brain metastases in less than 12 months was significantly associated with presence of visceral metastases. This however is a feature of most Her2-positive tumours, therefore, this subgroup awaits further specification.

### Table 7: Cox proportional hazard model: Prediction of OS

| Factor                                      | p    | OR   | 95% CI  |
|---------------------------------------------|------|------|---------|
| Age < 35 years                              | 0.083| 2.1  | 0.91-4.86|
| Positive hormone receptor status            | 0.075| 0.61 | 0.36-1.05|
| Number of metastatic sites (1 versus 2)     | 0.053| 4.2  | 1.74-1.01|
| Development of brain metastases             | 0.292| 1.35 | 0.77-2.37|
| Early development of brain metastases       | 0.001| 3.83 | 1.68-8.71|
a subgroup of patient may benefit from trastuzumab-treatment in multiple lines. On the other hand, we were not able to identify clinical or histopathological markers predicting for activity of this approach. Therefore, identification of other biomarkers of trastuzumab resistance is urgently warranted.
