Spinor states of real rational curves in real algebraic convex 3-manifolds and enumerative invariants

Jean-Yves Welschinger*

31st December 2021

Abstract:
Let $X$ be a real algebraic convex 3-manifold whose real part is equipped with a $Pin^-$ structure. We show that every irreducible real rational curve with non-empty real part has a canonical spinor state belonging to $\{\pm 1\}$. The main result is then that the algebraic count of the number of real irreducible rational curves in a given numerical equivalence class passing through the appropriate number of points does not depend on the choice of the real configuration of points, provided that these curves are counted with respect to their spinor states. These invariants provide lower bounds for the total number of such real rational curves independently of the choice of the real configuration of points.

Introduction

A smooth complex algebraic projective manifold $X$ is said to be convex when the vanishing $H^1(\mathbb{C}P^1; u^*TX) = 0$ occurs for every morphism $u : \mathbb{C}P^1 \to X$. Main examples are homogeneous spaces. These manifolds provide a suitable framework in order to define genus 0 algebraic Gromov-Witten invariants since the space of morphisms from $\mathbb{C}P^1$ to $X$ in a given homology class $d \in H_2(X; \mathbb{Z})$ turns out to be a smooth manifold of the expected dimension $c_1(X)d + 3$ (see [8], [2]). In particular, these Gromov-Witten invariants are enumerative. Let $X$ be a convex manifold of dimension 3 and $d \in H_2(X; \mathbb{Z})$ be such that $c_1(X)d$ is even. Let $k_d$ be half of this even integer. Then, through a generic configuration $\underline{x} = (x_1, \ldots, x_{k_d})$ of $k_d$ distinct points of $X$ passes only finitely many connected rational curves in the homology class $d$. These curves are all irreducible and immersed and their number $N_d$ does not depend on the choice of $\underline{x}$. It is a Gromov-Witten invariant of the manifold $X$, often denoted by $GW(X, d, pt, \ldots, pt)$. From now on, assume that $X$ is real, that is equipped with an antiholomorphic involution $c_X$. The fixed point set of $c_X$ is denoted by $RX$ and called the real part of $X$. Assume also that $(c_X)_*d = -d$ and that the configuration $\underline{x}$ is real, that is satisfies $\{c_X(x_1), \ldots, c_X(x_{k_d})\} = \{x_1, \ldots, x_{k_d}\}$. Then, the analogous result is no more true, the number $R_d(\underline{x})$ of irreducible rational curves in the homology class $d$ passing through $\underline{x}$ that are real depends in general on the choice of $\underline{x}$. The parity of this integer is however invariant, it is the one of $N_d$. The main purpose of this paper is to refine this mod(2) invariant into an integer valued one, see Theorem 2.2.

Fix a $Pin_3^-$ structure $p$ on $\mathbb{R}X$ (see [2.1]) and assume that $x \cap \mathbb{R}X \neq \emptyset$. As soon as the choice of $x$ is generic enough, this implies that for every curve $A \in R_d(x)$, where $R_d(x)$ denotes the set of real irreducible rational curves in the homology class $d$ passing through $x$, the real part $\mathbb{R}A$ is nonempty. Also, as soon as $x$ is generic enough, the normal bundle $N_A$ of $A$ in $X$ is real and balanced, that is the direct sum of two isomorphic holomorphic line bundles. Choosing a real subline bundle of $N_A$ of maximal degree $k_d - 1$, we can equip the knot $\mathbb{R}A \subset \mathbb{R}X$ with a canonical ribbon structure, see [2.2] for the detailed construction. This structure does depend on the way the complex curve $A$ is immersed in the complex manifold $X$ and it is inherited from this complex immersion. Associating a framing to this ribbon knot, we construct a loop in the $O_3(\mathbb{R})$-principal bundle $R_X$ of orthonormal frames of $\mathbb{R}X$. The spinor state $sp(A) \in \{\pm 1\}$ of $A$ is then defined to be the obstruction to lift this loop into a loop of the $Pin_3^-$-principal bundle $P_X$ given by the pin structure $p$. Denote by $(\mathbb{R}X)_1, \ldots , (\mathbb{R}X)_n$ the connected components of $\mathbb{R}X$ and, for $i \in \{1, \ldots , n\}$, by $r_i = \#(x \cap (\mathbb{R}X)_i)$. Then define

$$\chi^{d,p}_r(x) = \sum_{A \in R_d(x)} sp(A),$$

where $r = (r_1, \ldots , r_n)$.

**Theorem 0.1** 1) As soon as $c_1(X)d \neq 4$, the integer $\chi^{d,p}_r(x)$ is independent of the choice of the real configuration $x \in X^{k_d}$, it only depends on $d,p$ and the $n$-tuple $r$. The same holds when $c_1(X)d = 4$ and $X$ does not have any non-immersed rational curve in the class $d$.

2) The similar construction and result hold for the blow up projective space $Y = \mathbb{C}P^3 \# \mathbb{C}P^3$ when the homology class $d$ satisfies $Exc.d \geq 0$, where $Exc$ is the exceptional divisor of $Y$.

Note that the blow up projective space is not convex, see [4] for the second part of this theorem [4.1]. See also Theorem 2.2 for a slightly more general statement in the case $c_1(X)d = 4$.

This integer $\chi^{d,p}_r(x)$ is denoted by $\chi^{d,p}_r$ and we put $\chi^{d,p}_r = 0$ as soon as it is not well defined. This allows to define the polynomial $\chi^{d,p}(T) = \sum_{r \in \mathbb{N}^n} \chi^{d,p}_r T^r \in \mathbb{Z}[T]$, where $T^r = T_1^{r_1} \ldots T_n^{r_n}$. This polynomial is of the same parity as the integer $k_d$ and each of its monomials actually only depends on one indeterminate. Theorem 0.1 means that the function $\chi^p : d \in H_2(X;\mathbb{Z}) \mapsto \chi^{d,p}(T) \in \mathbb{Z}[T]$ is an invariant associated to the isomorphism class of the real algebraic convex manifold $(X,c_X)$. As an application, this invariant provides the following lower bounds in real enumerative geometry.

**Corollary 0.2** Under the assumptions of Theorem 0.1, we have

$$|\chi^{d,p}_r| \leq R_d(x) \leq N_d,$$

independently of the choice of $x \in X^{k_d}$.

Note that a similar invariant and similar lower bounds have already been obtained in [14], [15] using real rational curves in real symplectic 4-manifolds. The question was then raised whether there exists such invariants in higher dimensions. The results presented here thus provide a partial answer to this question.

Let us fix now $(X,c_X) = (\mathbb{C}P^3, conj)$ and a spin structure $s$ on $\mathbb{R}P^3$. Note that for orientable components of $\mathbb{R}X$, a spin structure is more convenient for us than a $Pin^-$ structure, see Remark 2.3. The $n$-tuple $r$ is then reduced to a single even integer between 2 and $2d = k_d$. 

2
Denote by \( Y = \mathbb{C}P^3 \# \overline{\mathbb{C}P^3} \) the blown up of \( X \) at a real point \( x_0 \). Denote by \( l \) the homology class of a line in the exceptional divisor \( \text{Exc} \) of \( Y \) and by \( f \) the class of the strict transform of a line in \( \mathbb{C}P^3 \) passing through \( x_0 \). Set \( d_Y = d(f + l) - 2l \) and choose a spin structure \( \mathfrak{s} \) on \( \mathbb{R}P^3 \). It induces a spin structure \( \# \mathfrak{s} \) on \( \mathbb{R}Y = \mathbb{R}P^3 \# \overline{\mathbb{R}P^3} \), see [4.2]. From the second part of Theorem 0.1, the integer \( \chi_{d_Y, s \# \mathfrak{s}} \) is well defined for \( r \) even between 2 and \( k_d - 2 \) and it is an invariant associated to \( Y \) together with its real structure. The following theorem provides relations between the coefficients of the polynomial \( \chi_{d,s}(T) \) for the projective space, see Theorem 1.3.

**Theorem 0.3** Let \( r \) be an even integer between 2 and \( k_d - 2 \), then

\[
\chi_{d,s}(r + 2) = \chi_{d,s}(r) - 2\chi_{d_Y, s \# \mathfrak{s}}(r).
\]

This paper is divided in four paragraphs. In the first one, we introduce Kontsevich’s space of stable maps and its real structures, as well as preliminaries on the evaluation map and Gromov-Witten invariants. In the second one, we introduce the definition of spinor states and state the main results of this paper. In the third one, we give a proof of these results. Finally, the last paragraph is devoted to a further study of the polynomial \( \chi_{d,s}(T) \) for the projective space, proving Theorem 1.3.

Acknowledgements:
I am grateful to V. Kharlamov and O. Viro for fruitful discussions on spin and pin structures. Part of this work has been done during my stay at the Université Louis Pasteur of Strasbourg in July 2003. I would like to acknowledge the warm hospitality of people working there.

Let \((X, c_X)\) be a real algebraic convex 3-manifold and \(d \in H_2(X; \mathbb{Z})\) be such that \((c_X)_*d = -d\).

1.1 Moduli space of genus 0 real stable maps with \(k\) marked points

Let \(\text{Mor}_d(X)\) be the set of morphisms \(u\) from \(\mathbb{C}P^1\) to \(X\) in the class \(d\), that is satisfying \(u_*[\mathbb{C}P^1] = d\). It is a smooth quasi-projective manifold of pure dimension \(c_1(X)d + 3\). Let \(k \in \mathbb{N}^*\) and \(\text{Diag}_k = \{(z_1, \ldots, z_k) \in (\mathbb{C}P^1)^k | \exists i \neq j, z_i = z_j\}\). The manifold \(\text{Mor}_d(X) \times ((\mathbb{C}P^1)^k \setminus \text{Diag}_k)\) is equipped with an action of the symmetric group \(S^k\) equipped with an antiholomorphic involution \(c_X\) to \(\mathbb{C}P^1\) for \((\sigma, (u, z_1, \ldots, z_k)) \in \mathcal{S}_k \times \mathcal{M}_0^d(X) \times ((\mathbb{C}P^1)^k \setminus \text{Diag}_k)\). Denote by \(\mathcal{M}_0^d(X)\) the quotient of \(\text{Mor}_d(X) \times ((\mathbb{C}P^1)^k \setminus \text{Diag}_k)\) by \(\text{Aut}(\mathbb{C}P^1)\). This moduli space is a quasi-projective manifold of pure dimension \(c_1(X)d + k\) and a complex orbifold. It is equipped with an action of \(\mathcal{S}_k\) with an antiholomorphic involution \(\gamma_{\mathcal{M}}\) induced by the action of \(\mathcal{M}_{0, k}(X)^*\) the complement of the set of maps \(u\) which can be written \(u' \circ g\) where \(u' : \mathbb{C}P^1 \to X\) and \(g : \mathbb{C}P^1 \to \mathbb{C}P^1\) is a non-trivial ramified covering. It is included in the smooth locus of \(\mathcal{M}_0^d(X)\). Denote by \(U_{0, k}^d(X) \to \mathcal{M}_0^d(X)^*\) the universal curve, which is obtained as the quotient of \(\text{Mor}_d(X) \times ((\mathbb{C}P^1)^k \setminus \text{Diag}_k) \times \mathbb{C}P^1\) by the action of \(\text{Aut}(\mathbb{C}P^1)\) and then restricted over \(\mathcal{M}_0^d(X)^*\). This universal curve is also equipped with an antiholomorphic involution \(c_{\mathcal{M}}\) and with an action of \(\mathcal{S}_k\) which lifts \(c_{\mathcal{M}}\) and the action of \(\mathcal{S}_k\) on \(\mathcal{M}_0^d(X)^*\) respectively. Finally, denote by \(\overline{\mathcal{M}}_{0, k}(X)\) the moduli space of genus 0 stable maps with \(k\) marked points in the homology class \(d\). This is the compactification due to M. Kontsevich of the space \(\mathcal{M}_0^d(X)\), see [8], [2]. Denote by \(\overline{\mathcal{M}}_{0, k}(X)^*\) the space of stable maps \((u, C, z_1, \ldots, z_k)\) for which \(u\) restricted to any irreducible component of \(C\) does not admit a factorization of the form \(u' \circ g\) where \(u' : \mathbb{C}P^1 \to X\) and \(g : \mathbb{C}P^1 \to \mathbb{C}P^1\) is a non-trivial ramified covering. Note that this in particular avoids maps \((u, C, z_1, \ldots, z_k)\) mapping a component of \(C\) to a constant, which does not matter for us since these maps will play no rôle in this paper. We recall the following theorem.

**Theorem 1.1** 1) The manifold \(\overline{\mathcal{M}}_{0, k}(X)^*\) is projective normal of pure dimension \(c_1(X)d + k\). It is a complex orbifold containing \(\overline{\mathcal{M}}_{0, k}(X)^*\) in its smooth locus, which is equipped with an evaluation morphism \(ev_{\mathcal{M}}^d : \overline{\mathcal{M}}_{0, k}(X)^* \to X^k\). Finally, the complement \(\overline{\mathcal{M}}_{0, k}(X)^* \setminus \mathcal{M}_0^d(X)^*\) is a divisor with normal crossings.

2) The curve \(U_{0, k}^d(X) \to \mathcal{M}_0^d(X)^*\) extends to a universal curve \(\overline{U}_{0, k}^d(X) \to \overline{\mathcal{M}}_{0, k}(X)^*\).
3) The real structures $c_M$ and $c_U$ extend to real structures $c_{\overline{M}}$ and $c_{\overline{U}}$ on $\overline{M}_{0,k}(X)$ and $\overline{U}_{0,k}(X)$ respectively. The same holds for the actions of $S_k$ on these spaces. □

This theorem is proved in [2], Theorems 2 and 3. The third part of this theorem follows from the fact that the construction presented in [2] can be carried out over the reals, see [9]. Note that the evaluation morphism restricted to $\overline{M}_{0,k}(X)$ is just the map induced by $(u, z_1, \ldots, z_k) \in \text{Mor}_d(X) \times ((\mathbb{C}P^1)^k \setminus \text{Diag}_k) \mapsto (u(z_1), \ldots, u(z_k)) \in X^k$.

For every element $\tau \in S_k$, denote by $\Phi_{\tau}$ the associated automorphism of $\overline{M}_{0,k}(X)$. This automorphism commutes with $c_{\overline{M}}$. When $\tau^2 = id$, put $c_{\overline{M},\tau} = \Phi_{\tau} \circ c_{\overline{M}}$ the associated real structure. Note that if $\tau'$ is different from $\tau$, then $c_{\overline{M},\tau} = \Phi_{\tau} \circ c_{\overline{M},\tau}$ is the vanishing order of $i$. From a theorem of Grothendieck, it splits as the direct sum of two line bundles $O_{\mathbb{C}P^1}(a) \oplus O_{\mathbb{C}P^1}(b)$, see §2.1 of [11] for example. This normal bundle is said to be balanced when $a = b$. The rational curve $(u, z_1, \ldots, z_k)$ is said to be balanced when $u$ is an immersion and $N_u$ is balanced. Note that when $u$ is an immersion, the adjunction formula imposes $a + b = c_1(X)d - 2$. Thus a necessary condition for the curve to be balanced is that $c_1(X)d$ is even.

Examples:
1) The rational curve $u : (t_0,t_1) \in \mathbb{C}P^1 \mapsto (t^d_0,t_0^{d-1}t_1,t_0t_1^{d-1},t_1^d) \in \mathbb{C}P^3$ is balanced as soon as $d \in \mathbb{N}$ is different from 2.
2) If $A \subset X^3$ is balanced and $Y$ is the blown up of $X^3$ at a point $x_0 \in A$, then the strict transform of $A$ in $Y$ is balanced, see Lemma 4.5.

1.2 Evaluation map and balanced curves

1.2.1 Balanced rational curves
Let $(u, z_1, \ldots, z_k) \in \text{Mor}_d(X) \times ((\mathbb{C}P^1)^k \setminus \text{Diag}_k)$. The differential of $u$ induces a morphism of sheaves $0 \rightarrow O_{\mathbb{C}P^1}(u^*TX)$. Denote by $N_u$ the quotient sheaf. This quotient sheaf admits a decomposition $O_{\mathbb{C}P^1}(N_u) \oplus N_u^{\text{sing}}$, where $N_u$ is the normal bundle of $u$ and $N_u^{\text{sing}}$ is the skyscraper sheaf having the critical points $p_i \in \mathbb{C}P^1$ as support, and $\mathbb{C}P^1$ as fibers, where $n_i$ is the vanishing order of $du$ at $p_i$. The bundle $N_u$ is holomorphic of rank two over $\mathbb{C}P^1$. From a theorem of Grothendieck, it splits as the direct sum of two line bundles $O_{\mathbb{C}P^1}(a) \oplus O_{\mathbb{C}P^1}(b)$, see §2.1 of [11] for example. This normal bundle is said to be balanced when $a = b$. The rational curve $(u, z_1, \ldots, z_k)$ is said to be balanced when $u$ is an immersion and $N_u$ is balanced. Note that when $u$ is an immersion, the adjunction formula imposes $a + b = c_1(X)d - 2$. Thus a necessary condition for the curve to be balanced is that $c_1(X)d$ is even.

Examples:
1) The rational curve $u : (t_0,t_1) \in \mathbb{C}P^1 \mapsto (t^d_0,t_0^{d-1}t_1,t_0t_1^{d-1},t_1^d) \in \mathbb{C}P^3$ is balanced as soon as $d \in \mathbb{N}$ is different from 2.
2) If $A \subset X^3$ is balanced and $Y$ is the blown up of $X^3$ at a point $x_0 \in A$, then the strict transform of $A$ in $Y$ is balanced, see Lemma 4.5.

1.2.2 Dominance of the evaluation map
From now on, we assume that $c_1(X)d$ is even and we set $k_d = \frac{1}{2}c_1(X)d$. Note that this condition is automatically fulfilled when $\mathbb{R}X$ is orientable and $d$ is realized by a real 2-cycle $A$, in which $c_1(X)[A] = u_1(\mathbb{R}X)[\mathbb{R}A] = 0 \mod (2)$.
Let $(u, \mathbb{C}P^1,z_1, \ldots, z_{kd}) \in M_{0,kd}(X)^\tau$ and set $N_{u,-z} = N_u \oplus O_{\mathbb{C}P^1}(-z)$, where $z = (z_1, \ldots, z_{kd}) \in (\mathbb{C}P^1)^{kd}$. Then, set $N_{u,-z} = O_{\mathbb{C}P^1}(N_{u,-z}) \oplus N_u^{\text{sing}}$. 

5
Lemma 1.2 Let \((u, \mathbb{C}P^1, z_1, \ldots, z_{k_d}) \in \mathcal{M}_{0, k_d}^d(X)^*\), the following isomorphisms occur:

\[
\ker(d|_{(u, \mathbb{C}P^1, z)} \circ \text{ev}_{k_d}^d) \cong H^0(\mathbb{C}P^1; N_{u,z}) \cong H^0(\mathbb{C}P^1; N_{u,-z}) \oplus H^0(\mathbb{C}P^1; N_u^{\text{sing}}),
\]

and \(\text{coker}(d|_{(u, \mathbb{C}P^1, z)} \circ \text{ev}_{k_d}^d) \cong H^1(\mathbb{C}P^1; N_{u,z}).\)

In particular, balanced curves are regular points of the evaluation map \(\text{ev}_{k_d}^d\).

Proof:
Denote by \(\text{eval}_{k_d}^d\) the map \((u, z_1, \ldots, z_{k_d}) \in \text{Mor}_d(X) \times ((\mathbb{C}P^1)^{k_d} \setminus \text{Diag}_{k_d}) \mapsto (u(z_1), \ldots, u(z_{k_d})) \in X^{k_d}\). The differential of this map at the point \((u, z)\) is given by \((v, \dot{z}) \in H^0(\mathbb{C}P^1; u^*TX) \times T_z(\mathbb{C}P^1)^{k_d} \mapsto v(z) + d|_z u(\dot{z}) \in T_{u(z)} X^{k_d}\). Denote by \(N_{\mid z} u\) the skyscraper sheaf with support \(\{z_1, \ldots, z_{k_d}\}\) and fiber \(T_{u(z)} X/d|_z u(T\mathbb{C}P^1)\) over \(z\). The cokernel of \(\dot{z} \in T_z(\mathbb{C}P^1)^{k_d} \mapsto d|_z u(\dot{z}) \in T_{u(z)} X^{k_d}\) is isomorphic to \(H^0(\mathbb{C}P^1; N_{\mid z} u)\). Thus, the cokernel of \(d|_{(u, z)} \circ \text{eval}_{k_d}^d\) is identified with the cokernel of the composition:

\[
\begin{align*}
H^0(\mathbb{C}P^1; u^*TX) & \to H^0(\mathbb{C}P^1; N_u) \to H^0(\mathbb{C}P^1; N_{\mid z} u) & (\ast) \\
v & \mapsto [v] & \mapsto [v(z)].
\end{align*}
\]

From the exact sequence of sheaves \(0 \to T\mathbb{C}P^1 \to u^*TX \to N_u \to 0\) we deduce that the first morphism of \((\ast)\) is surjective since \(H^1(\mathbb{C}P^1; T\mathbb{C}P^1) = 0\) and that \(H^1(\mathbb{C}P^1; N_u) = 0\) since \(X\) is convex. From the short exact sequence of sheaves \(0 \to N_{u,z} \to N_u \to N_{\mid z} u \to 0\), we deduce the long exact sequence

\[
\cdots \to H^0(\mathbb{C}P^1; N_u) \to H^0(\mathbb{C}P^1; N_{\mid z} u) \to H^1(\mathbb{C}P^1; N_{u,z}) \to H^1(\mathbb{C}P^1; N_u) \to \cdots
\]

Since \(H^1(\mathbb{C}P^1; N_u) = 0\), the cokernel of the second morphism of \((\ast)\) is isomorphic to \(H^1(\mathbb{C}P^1; N_{u,z})\). Thus, the cokernel of \(d|_{(u, z)} \circ \text{eval}_{k_d}^d\) and hence the cokernel of \(d|_{(u, \mathbb{C}P^1, z)} \circ e_{k_d}^d\) is isomorphic to \(H^1(\mathbb{C}P^1; N_{u,z})\).

In the same way, the kernel of the map \(d|_{(u, \mathbb{C}P^1, z)} \circ e_{k_d}^d\) is isomorphic to the quotient of the kernel of the composition \((\ast)\) with the image of the morphism \(d u : H^0(\mathbb{C}P^1; T\mathbb{C}P^1) \to H^0(\mathbb{C}P^1; u^*TX)\). Indeed, the latter coincide with the infinitesimal action of \(\text{Aut}(\mathbb{C}P^1)\) on \(\text{Mor}_d(X)\). Since the quotient of \(H^0(\mathbb{C}P^1; u^*TX)\) by \(d u (H^0(\mathbb{C}P^1; T\mathbb{C}P^1))\) is isomorphic to \(H^0(\mathbb{C}P^1; N_u)\), we deduce that the kernel of \(d|_{(u, \mathbb{C}P^1, z)} \circ e_{k_d}^d\) is isomorphic to the kernel of the second morphism of \((\ast)\), that is to \(H^0(\mathbb{C}P^1; N_{u,z})\). \(\square\)

Proposition 1.3 Let \((u, C, z) \in \overline{\mathcal{M}}_{0, k_d}^d(X)^*\) be such that \(C\) has two irreducible components \(C_1\) and \(C_2\) for which \(u(C_1), u(C_2)\) are balanced and meet in a single ordinary double point away from \(u(z)\). Assume moreover that for \(i \in \{1, 2\}\), \(#(C_i \cap z) = \frac{1}{2} c_1(X) d_i\) where \(d_i = u_*[C_i] \in H_2(X; \mathbb{Z})\). Then, \((u, C, z)\) is a regular point of \(e_{k_d}^d\).

Proof:
For \(i \in \{1, 2\}\), set \(k_{d_i} = \frac{1}{2} c_1(X) d_i\), \(u_i = u|_{C_i}\) and \(z_i = C_i \cap z\). Denote by \(\mathcal{K} = \overline{\mathcal{M}}_{0, k_d}^d(X)^* \setminus \mathcal{M}_{0, k_d}^d(X)^*\) the divisor of stable maps having reducible domain. Then \((u, C, z)\) is a smooth point of \(\mathcal{K}\). Indeed, for \(i \in \{1, 2\}\), denote by \(e_i : \overline{\mathcal{M}}_{0, k_d, \bullet}^d(X) \to X\) the evaluation map associated to the additional marked point \(\bullet\). Since \(u(C_i)\) is balanced, \(d|_{(u_i, C_i, z_i \cup (C_1 \cap C_2))} e_i\) is surjective. Thus, \(((u_1, C_1, z_1 \cup (C_1 \cap C_2)), (u_2, C_2, z_2 \cup (C_1 \cap C_2)))\) is a smooth point of
Lemma 1.4. Let $\overline{K} = (e_1 \times e_2)^{-1}(\text{Diag}_X)$, where $\text{Diag}_X \subset X \times X$ is the diagonal. From Lemma 12(i) of [2], the map $\overline{K} \to K$ is an isomorphism, hence $(u, C, z)$ is a smooth point of $K$.

Now, the restriction of $e^{d}_{k_d}$ to $K$ in the neighborhood of $(u, C, z)$ writes as the composition of the morphism of restriction $(u, C_1 \cup C_2, z) \in K \mapsto ((u_1, C_1, z^1), (u_2, C_2, z^2)) \in M^{d_1}_{0,k_d}(X) \times M^{d_2}_{0,k_d}(X)$ and the morphism of evaluation $e^{d_1}_{k_d} \times e^{d_2}_{k_d} : M^{d_1}_{0,k_d}(X) \times M^{d_2}_{0,k_d}(X) \to X^{k_d}$. Since $u(C_1)$ and $u(C_2)$ meet in only one ordinary double point, the first morphism is injective in a neighborhood of $(u, C, z)$. Since $u(C_1)$ and $u(C_2)$ are balanced, from Lemma 12 the second morphism is an isomorphism in the neighborhood of $((u_1, C_1, z^1), (u_2, C_2, z^2))$. Hence, to prove proposition 13 it suffices to prove that $e^{d}_{k_d}$ is injective when restricted to a transversal of $K$ at the point $(u, C, z)$. Since $e^{d}_{k_d}(K)$ is smooth in a neighborhood of $u(z)$, a transversal to this divisor can be chosen in one factor of $X^{k_d}$, that is of the form $\gamma : t \in \Delta \mapsto (x_1(t), \ldots, x_{k_d}(t)) \in X_{k_d}$ where only one point $x_i(t)$, say $x_{k_d}(t)$, indeed depends on $t$. Since such a path is transversal to $e^{d}_{k_d}$, its inverse image is a smooth curve $B$ in $\overline{M}^{d}_{0,k_d}(X)^*$ transversal to $K$ at the point $(u, C, z)$. Denote by $U \to B$ the restriction of $\overline{U}^{d}_{0,k_d}(X) \to \overline{M}^{d}_{0,k_d}(X)^*$ over $B$. This universal curve has one unique reducible fiber over $(u, C, z)$ (choosing a smaller $B$ if necessary) and $k_d$ tautological sections $s_1, \ldots, s_{k_d} : B \to U$.

The evaluation morphism $e_U : U \to X$ contracts the curves $\text{Im}(s_1), \ldots, \text{Im}(s_{k_d-1})$ and we have to prove that it is injective when restricted to $\text{Im}(s_{k_d})$. This follows from the following Lemma 13. \hfill \Box

**Lemma 1.4** The differential of the evaluation morphism $e_U : U \to X$ defined above is injective at every point of the central fiber $C \setminus \{z_1, \ldots, z_{k_d-1}\}$.

**Proof:**

Without loss of generality, we can assume that $z^1 = \{z_1, \ldots, z_{k_{d_1}}\}$ and $z^2 = \{z_{k_{d_1}+1}, \ldots, z_{k_d}\}$. Since $u|_{C_1}$ and $u|_{C_2}$ are immersions, the rank of $\text{dev}_U$ is at least one at each point of $C$. Now, the normal bundle of $C_1$ in $U$ is isomorphic to $\mathcal{O}_{C_1}(-1)$. The morphism $\text{dev}_U$ thus induces a morphism of sheaves $0 \to \mathcal{O}_{C_1}(-1) \to \mathcal{O}_{C_1}(N_{u_1})$ where $u_1 = u|_{C_1}$. Since this morphism vanishes at the points $z_1, \ldots, z_{k_{d_1}}$, its image is a subline bundle of $N_{u_1}$ of degree at least $k_{d_1} - 1$. From the isomorphism $N_{u_1} \cong \mathcal{O}_{C_1}(k_{d_1} - 1) \oplus \mathcal{O}_{C_1}(k_{d_1} - 1)$, we deduce that this subline bundle has degree exactly $k_{d_1} - 1$. This implies that the morphism of sheaves vanishes nowhere else than at the points $z_1, \ldots, z_{k_{d_1}}$ and thus $\text{dev}_U$ is of rank two at each point of $C_1 \setminus z^1$. Similarly, the normal bundle of $C_2$ in $U$ is isomorphic to $\mathcal{O}_{C_2}(-1)$. The morphism $\text{dev}_U$ thus induces a morphism of sheaves $0 \to \mathcal{O}_{C_2}(-1) \to \mathcal{O}_{C_2}(N_{u_2})$, where $u_2 = u|_{C_2}$, which vanishes at the points $z_{k_{d_1}+1}, \ldots, z_{k_d-1}$. The image of this morphism is thus a subline bundle $L$ of $N_{u_2}$ of degree at least $k_{d_2} - 2$. Denote by $L_1$ the unique subline bundle of $N_{u_2} \cong \mathcal{O}_{C_2}(k_{d_2} - 1) \oplus \mathcal{O}_{C_2}(k_{d_2} - 1)$ which is of degree $k_{d_2} - 1$ and contains the tangent line of $u(C_1)$ at $u(C_1) \cap u(C_2)$. Denote by $M_1$ the quotient $N_{u_2}/L_1$, it is a line bundle of degree $k_{d_2} - 1$. The bundle $L_1$ corresponds to infinitesimal deformations of the curve $u(C_2)$ into a curve passing through $u(z_{k_{d_1}+1}), \ldots, u(z_{k_d-1})$ and $u(C_1)$. Since by construction $B$ is transversal to the divisor $K$ of reducible curves of $\overline{M}^{d}_{0,k_d}(X)^*$, one has $L \neq L_1$. However, $L$ also contains the tangent line of $u(C_1)$ at $u(C_1) \cap u(C_2)$. It follows that the morphism of sheaves $0 \to \mathcal{O}_{C_2}(L) \to \mathcal{O}_{C_2}(M_1)$ induced by the projection $N_{u_2} \to M_1$ vanishes at the point $u(C_1) \cap u(C_2)$. This implies that $\deg(L) \leq \deg(M_1) - 1 = k_{d_2} - 2$. Hence, the line bundle $L$ is of degree exactly $k_{d_2} - 2$ and $\text{dev}_U$ is of rank two at each point of $C_2 \setminus \{z_{k_{d_1}+1}, \ldots, z_{k_d-1}\}$. 7
The result follows. □

**Proposition 1.5** Let \((u, C, z) \in \overline{\mathcal{M}}^d_{0,k d}(X)^*\) be such that \(C\) has two irreducible components \(C_1\) and \(C_2\) for which \(u(C_1), u(C_2)\) are immersed and meet in a single ordinary double point away from \(u(z)\). For \(i \in \{1, 2\}\), denote by \(z^i = C_i \cap z\), \(d_i = u_i|C_i \in H_2(X; \mathbb{Z})\), \(k_{d_1} = E(\frac{1}{2}C_1(X)d_1)\) and \(k_{d_2} = E(\frac{1}{2}C_1(X)d_2) + 1\) where \(E()\) denotes the integer part. Assume that \(N_{u_i|C_1} \cong \mathcal{O}_{C_1}(k_{d_1} - 1) \oplus \mathcal{O}_{C_1}(k_{d_1})\), \(N_{u_i|C_2} \cong \mathcal{O}_{C_2}(k_{d_2} - 2) \oplus \mathcal{O}_{C_2}(k_{d_2} - 1)\) and that the tangent line to \(u(C_1)\) (resp. to \(u(C_2)\)) at the point \(u(C_1) \cap u(C_2)\) is not mapped to the unique subline bundle of degree \(k_{d_2} - 1\) (resp. \(k_{d_1}\)) of \(N_{u_i|C_2}\) (resp. \(N_{u_i|C_1}\)). Then, \((u, C, z)\) is a regular point of \(ev_{k d}^d\).

**Proof:**

As in the proof of proposition [1.3] the divisor \(\mathcal{K} = \overline{\mathcal{M}}^d_{0,k d}(X)^* \setminus \mathcal{M}^d_{0,k d}(X)^*\) is smooth in a neighborhood of \((u, C, z)\). Moreover, \(ev_{k d}^d\) restricted to \(\mathcal{K}\) is injective in the neighborhood of \((u, C, z)\). Indeed, this restriction writes as the composition of the morphism \((u, C_1 \cup C_2, z) \in \mathcal{K} \mapsto ((u_1, C_1, z^1), (u_2, C_2, z^2)) \in \mathcal{M}^d_{0,k d_1}(X) \times \mathcal{M}^d_{0,k d_2}(X)\) and the morphism of evaluation \(ev_{k d_1}^d \times ev_{k d_2}^d : \mathcal{M}^d_{0,k d_1}(X) \times \mathcal{M}^d_{0,k d_2}(X) \rightarrow X^{k d}\), where \(u_1 = u|C_1\) and \(u_2 = u|C_2\). It follows from the hypothesis that the first morphism is injective. Also, from Lemma [1.2] the morphism \(d|_{(u_2, C_2, z)} ev_{k d_2}^d\) is injective and \(d|_{(u_1, C_1, z)} ev_{k d_1}^d\) is surjective. We deduce from the hypothesis that the composition of these morphisms, that is \(ev_{k d}^d|_{\mathcal{K}}\), is injective. It suffices thus to prove that the restriction of \(ev_{k d}^d\) to a transversal of \(\mathcal{K}\) at the point \((u, C, z)\) is injective. Without loss of generality, we can assume that \(z^1 = \{z_1, \ldots, z_{k_{d_1}}\}\) and \(z^2 = \{z_{k_{d_1} + 1}, \ldots, z_{k_{d_2}}\}\). Since \(ev_{k d}^d(\mathcal{K})\) is smooth in a neighborhood of \((u, z)\) and its projection on the first \(k_{d_1}\) factors of \(X^{k d}\) is onto, a transversal to this divisor can be chosen of the form \(\gamma : t \in \Delta \mapsto (x_1(t), \ldots, x_{k_{d_1}}(t)) \in X_{k d}\) where only one point \(x_j(t)\), say \(x_{k_{d_1}}(t)\), depends on \(t\). The inverse image of this path is a smooth curve \(B\) in \(\overline{\mathcal{M}}^d_{0,k d}(X)^*\) transversal to \(\mathcal{K}\) at the point \((u, C, z)\). Denote by \(U \rightarrow B\) the restriction of \(\overline{\mathcal{M}}^d_{0,k d}(X) \rightarrow \overline{\mathcal{M}}^d_{0,k d}(X)^*\) over \(B\) and by \(s_1, \ldots, s_{k d} : B \rightarrow U\) the tautological sections. The evaluation morphism \(ev_U : U \rightarrow X\) contracts the curves \(Im(s_1), \ldots, Im(s_{k d-1})\) and we have to prove that it is injective once restricted to \(Im(s_{k d})\). But the normal bundle of \(C_1\) (resp. \(C_2\)) in \(U\) is isomorphic to \(\mathcal{O}_{C_1}(-1)\) (resp. \(\mathcal{O}_{C_2}(-1)\)). The morphism \(dev_U\) maps this line bundle onto a subline bundle of degree at least \(k_{d_1} - 1\) (resp. \(k_{d_2} - 2\)) of \(N_{u_1}\) (resp. \(N_{u_2}\)) since this morphism vanishes exactly at the points \(z_1, \ldots, z_{k_{d_1}}\) (resp. \(z_{k_{d_1}+1}, \ldots, z_{k_{d_2}-1}\)). Now this subline bundle contains the tangent line of \(u(C_2)\) (resp. \(u(C_1)\)) at the point \(u(C_1) \cap u(C_2)\). Thus, it cannot be the unique subline bundle of degree \(k_{d_1}\) (resp. \(k_{d_2} - 1\)) of \(N_{u_1}\) (resp. \(N_{u_2}\)). It follows that this subline bundle is of degree exactly \(k_{d_1} - 1\) (resp. \(k_{d_2} - 2\)) which implies that \(dev_U\) is injective at every point of \(C \setminus \{z_1, \ldots, z_{k_{d_2}-1}\}\). Hence the result. □

**Remark 1.6** With the help of an expression of the cokernel of the evaluation map at reducible curves analogous to the one given in Lemma [1.2] it would be possible to reduce the proofs of Propositions [1.3] and [1.5] to some vanishing results, compare §1.2 of [7].

1.3 Relation with the Gromov-Witten invariants

**Proposition 1.7** Let \(X\) be a convex manifold of dimension 3 and \(d \in H_2(X; \mathbb{Z})\) be an effective homology class such that \(C_1(X)d\) is even. Denote by \(k_d = \frac{1}{2}C_1(X)d\). Then, the following are equivalents:
i) The morphism \( ev_{k_d}^d \) is dominant.

ii) There exists an irreducible rational curve in the class \( d \) which is balanced.

iii) The genus 0 Gromov-Witten invariant \( GW(X,d,pt,\ldots,pt) \) does not vanish.

Proof:

i) \( \Rightarrow \) ii) Let \( \underline{x} \in X^{k_d} \) be a regular value of \( ev_{k_d}^d \) which does not belong to the image of \( \mathcal{K} = \overline{\mathcal{M}}_{0,k_d}(X) \setminus \mathcal{M}_{0,k_d}^d(X)^* \). Then by hypothesis there exists \((u,C,z) \in \mathcal{M}_{0,k_d}^d(X)^* \) such that \( u(z) = \underline{x} \) and \( \ker d|_{(u,C,z)ev_{k_d}^d} = 0 \). From lemma [2] this means that \( H^1(C, N_{u,z}) = 0 \). Now \( N_{u,z} \) is isomorphic to \( \mathcal{O}_C(a-k_d) \oplus \mathcal{O}_C(b-k_d) \) with \( a+b \leq 2k_d - 2 \). This condition thus implies that \( a = b = k_d - 1 \), which means that \( u \) is immersed and balanced.

ii) \( \Rightarrow \) i) Follows from lemma [2] and the implicit function theorem.

iii) \( \iff \) i) Let \( \underline{x} \in X^{k_d} \) be a regular value of \( ev_{k_d}^d \) which does not belong to \( ev_{k_d}^d(\mathcal{K}) \). Then, by definition, \( GW(X,d,pt,\ldots,pt) = #(ev_{k_d}^d)^{-1}(\underline{x}) \). Hence the equivalence. \( \square \)

In particular, we deduce from Example 1 of [12,1] the following well known corollary.

Corollary 1.8 If \( X = \mathbb{C}P^3 \) and \( d \neq 2[\mathbb{C}P^1] \in H_2(X;\mathbb{Z}) \) is effective, then the evaluation map \( ev_{k_d}^d \) is dominant and the genus 0 Gromov-Witten invariant \( GW(X,d,pt,\ldots,pt) \) does not vanish. \( \square \)

For some computations of such Gromov-Witten invariants, see [12, 2] and references therein.

2 Main results

2.1 Choice of a \( \text{Pin}^- \) structure \( \mathfrak{p} \) on \( \mathbb{R}X \)

Let \( (X,c_X) \) be a real algebraic convex 3-manifold. Equip the real part \( \mathbb{R}X \) with a riemannian metric \( g \) and denote by \( R_X \) the \( O_3(\mathbb{R}) \)-principal bundle of orthonormal frames of \( TR_X \). Remember that the double covering of \( O_3(\mathbb{R}) \) which is non-trivial over each of its connected components can be provided two different group structures turning the covering map into a morphism. The one for which the lift of a reflexion is of order 4 is denoted by \( \text{Pin}^-_3 \), see [1]. The obstruction to lift the \( O_3(\mathbb{R}) \)-principal bundle \( R_X \) into a \( \text{Pin}^-_3 \)-principal bundle is given by the expression \( w_2(R_X) + w^*_1(R_X) \in H^2(\mathbb{R}X;\mathbb{Z}/2\mathbb{Z}) \) where \( w_1(R_X) \) (resp. \( w_2(R_X) \)) stands for the first (resp. second) Stiefel-Whitney class of \( \mathbb{R}X \), see [6] for instance. Now from Wu relations (see [10], p. 132 for instance), the obstruction \( w_2(M) + w^*_1(M) \) vanishes for every compact 3-manifold \( M \). From now on, we will thus fix such a \( \text{Pin}^-_3 \)-structure \( \mathfrak{p} \) on \( \mathbb{R}X \) and denote by \( P_X \) the associated \( \text{Pin}^-_3 \)-principal bundle. Note that on orientable components of \( \mathbb{R}X \), the choice of an orientation allows to reduce the \( \text{Pin}^-_3 \) structure into a \( \text{Spin}_3 \) structure.

2.2 Spinor states of balanced real rational curves

Let \( (A,c_A) \subset (X,c_X) \) be a balanced irreducible real rational curve realizing the homology class \( d \) and with nonempty real part \( \mathbb{R}A \). In particular, \( \mathbb{R}A \) is an immersed knot in \( \mathbb{R}X \) and the normal bundle \( N_A \) of \( A \) is a real holomorphic vector bundle isomorphic to \( O_A(k_d - 1) \oplus O_A(k_d - 1) \) where \( k_d = \frac{1}{2}c_1(X)d \in \mathbb{N}^* \). Assume that \( \mathbb{R}A \) has a marked point \( x_0 \) and fix an orientation on \( T_{x_0}\mathbb{R}X \). Since \( w_1(\mathbb{R}X)[\mathbb{R}A] = c_1(X)[A] = 0 \mod (2) \), this orientation induces an orientation on \( TR_X|_{\mathbb{R}A} \). The real ruled surface \( P(N_A) \cong \mathbb{C}P^1 \times \mathbb{C}P^1 \) has a real part
Define then a spinor state $\text{sp}$ is a loop of direct orthonormal frames of $T_x\mathbb{R}A$ followed by a direct orthonormal frame of $\mathbb{R}N_A|_x$ provides a direct orthonormal frame of $T_x\mathbb{R}X$ for every $x \in \mathbb{R}A$. Denote by $h$ the class of the real part of a section of $P(N_A)$ having vanishing self-intersection, which is equipped with the orientation induced by the one of $\mathbb{R}A$. Similarly, denote by $f$ the class of a real fiber of $P(\mathbb{R}N_A)$, which is equipped with the orientation induced by the one of $\mathbb{R}N_A$. Then the couple $(h, f)$ provides a basis of the lattice $H_1(\mathbb{R}N_A; \mathbb{Z})$. Choose a real holomorphic subline bundle $L \subset N_A$ such that $P(L) \subset P(N_A)$ is a section with vanishing self-intersection if $k_d$ is odd and a section of bidegree $(1, 1)$ whose real part is homologous to $\pm (h + v) \in H_1(\mathbb{R}N_A; \mathbb{Z})$ otherwise. The line bundle $L$ is then of degree $k_d - 1$ if $k_d$ is odd and $k_d - 2$ otherwise. In both case, the real part $\mathbb{R}L$ is an orientable real line bundle. Denote by $\mathbb{R}E \supset T\mathbb{R}A$ the real rank two sub-bundle of $T\mathbb{R}X$ which projects onto $\mathbb{R}L$. This bundle is equipped with a riemannian metric induced by the one of $T\mathbb{R}X$. Choose then $(e_1(p), e_2(p))_{p \in \mathbb{R}A}$ a loop of orthonormal frames of $\mathbb{R}E$ such that $(e_1(p))_{p \in \mathbb{R}A}$ is a loop of direct orthonormal frames of $T\mathbb{R}A$. Note that this choice is not unique since $(e_1(p), -e_2(p))_{p \in \mathbb{R}A}$ provides another such choice. Let $(e_3(p))_{p \in \mathbb{R}A}$ be the unique section of $T\mathbb{R}X|_{\mathbb{R}A}$ such that $(e_1(p), e_2(p), e_3(p))_{p \in \mathbb{R}A}$ is a loop of direct orthonormal frames of $T\mathbb{R}X|_{\mathbb{R}A}$. Define then $\text{sp}(A) = +1$ if this loop of $\mathbb{R}X$ lifts to a loop of the bundle $P_X$ and $\text{sp}(A) = -1$ otherwise. This integer is called the spinor state of the curve $A$.

It neither depends on the choice of $L$ nor on the choice of the orientation on $\mathbb{R}A$ or on the metric $g$. It only depends on the pin structure $\mathfrak{p}$ and on the choice of the orientation on $T_x\mathbb{R}X$ when $k_d$ is even. Indeed, reversing this orientation change $\text{sp}(A)$ into its opposite in this case. Note that this spinor state is inherited from the complex immersion of $A$ in $X$ and does depend on this immersion, not just on the immersion of $\mathbb{R}A$ in $\mathbb{R}X$.

**Remark 2.1** 1) A spinor state for non-balanced real rational curve can be defined as well, but only the balanced case will be relevant for our purpose.

2) A more geometric explanation of our construction can be given as follows. The choice of a real holomorphic section $h \in P(N_A)$ with vanishing self-intersection provides a canonical - homotopy class of - ribbon structure on our knot. In case our ribbon is a M"obius strip, we have to cut this ribbon and perform half a twist in some direction before gluing it again in order to get cylinder and be able to associate some framing. This happens exactly when $k_d$ is even. The choice of the homology class $\pm (h + v)$ instead of $\pm (h - v)$ in the above construction is equivalent to the choice of such a direction. The point is that fixing an orientation on the tangent bundle over our knot is enough to fix a choice of such a direction without ambiguity.
2.3 Statement of the results

Let \((X, c_X)\) be a smooth real algebraic convex 3-manifold. Denote by \((\mathbb{R}X)_1, \ldots, (\mathbb{R}X)_n\) the connected components of its real part \(\mathbb{R}X\) and equip them with a \(\text{Pin}_3^-\) structure \(p\), see \(\S\).

Let \(d \in H_2(X; \mathbb{Z})\) be a class realized by real rational curves, such that \(c_1(X)d\) is even and \(k_d = \frac{1}{2}c_1(X)d \in \mathbb{N}^*\).

Let \(\mathfrak{x}\) be a real configuration of \(k_d\) distinct points of \(X\), that is a configuration of \(k_d\) distinct points which are either real or exchanged by the involution \(c_X\). For \(i \in \{1, \ldots, n\}\), denote by \(r_i = \#(\mathfrak{x} \cap (\mathbb{R}X)_i)\) and assume that \(\sum_{i=1}^n r_i \neq 0\). Note that the \(n\)-tuple \(r = (r_1, \ldots, r_n)\) encodes the equivariant isotopy class of \(\mathfrak{x}\). As soon as the choice of \(\mathfrak{x}\) is generic enough, there are only finitely many connected rational curves in the homology class \(d\) passing through \(\mathfrak{x}\). Moreover, these curves are all irreducible and balanced and their number does not depend on the generic choice of \(\mathfrak{x}\); it is equal to the genus 0 Gromov-Witten invariant \(N_d = GW(X, d, pt, \ldots, pt)\).

Denote by \(\mathcal{R}_d(\mathfrak{x})\) the subset of these curves which are real and by \(\mathcal{R}_d(\mathfrak{x})\) its cardinality. Since \(\sum_{i=1}^n r_i \neq 0\) and \(\mathfrak{x}\) is generic, every curve \(A \in \mathcal{R}_d(\mathfrak{x})\) has nonempty real part. We can assume that all the real points of \(\mathfrak{x}\) are in a same connected component of \(\mathbb{R}X\), say \((\mathbb{R}X)_1\), since otherwise \(\mathcal{R}_d(\mathfrak{x})\) is empty. Choose such a real point, say \(x_{k_d}\), as well as an orientation of \(T_{x_{k_d}} \mathbb{R}X\), and denote by \(\mathfrak{r}\) the equivariant isotopy class of \(\mathfrak{x}\) together with \(x_{k_d}\) enriched with an orientation on \(T_{x_{k_d}} \mathbb{R}X\). Then, every curve \(A \in \mathcal{R}_d(\mathfrak{x})\) has a well defined spinor state. Define finally:

\[
\chi_{\mathfrak{r}}^{d, p}(\mathfrak{x}) = \sum_{A \in \mathcal{R}_d(\mathfrak{x})} sp(A) \in \mathbb{Z}.
\]

**Theorem 2.2** Let \((X, c_X)\) be a smooth real algebraic convex 3-manifold and \(p\) be a \(\text{Pin}_3^-\) structure on \(\mathbb{R}X\). Let \(d \in H_2(X; \mathbb{Z})\) be such that \(c_1(X)d\) is even and different from 4, and \(k_d = \frac{1}{2}c_1(X)d \in \mathbb{N}^*\). Let \(\mathfrak{x} = (x_1, \ldots, x_{k_d})\) be a real configuration of \(k_d\) distinct points with at least one of them real, say \(x_{k_d}\), and \(\mathfrak{r}\) be the equivariant isotopy class of \(\mathfrak{x}\) together with \(x_{k_d}\) enriched with an orientation on \(T_{x_{k_d}} \mathbb{R}X\) if \(k_d\) is even. Then the integer \(\chi_{\mathfrak{r}}^{d, p}(\mathfrak{x})\) does not depend on the choice of \(\mathfrak{x}\); it only depends on \(d, p\) and \(\mathfrak{r}\). The same holds when \(c_1(X)d = 4\) and the set of non-immersed rational curves of \(X\) in the class \(d\) is of codimension at least 2 in the moduli space \(\mathcal{M}_d^{g, k_d}(X)\).

(See Remark \(\S\) for a discussion on the condition \(c_1(X)d \neq 4\). In fact, I don’t know any convex 3-fold having a non-immersed curve whose homology class \(d\) satisfies \(c_1(X)d = 4\). Similarly, I don’t know any real convex 3-manifold having non-vanishing Gromov-Witten invariants and a non-connected real part.)

This integer \(\chi_{\mathfrak{r}}^{d, p}(\mathfrak{x})\) is denoted by \(\chi_{\mathfrak{r}}^{d, p}\) and we set \(\chi_{\mathfrak{r}}^{d, p} = 0\) as soon as it is not well defined.

**Corollary 2.3** Under the assumptions of Theorem \(\S\) assume in addition that \(k_d\) is even and that \(\mathbb{R}X\) has a non-orientable component \((\mathbb{R}X)_i\), \(i \in \{1, \ldots, n\}\). If \(r = (r_1, \ldots, r_n)\) with \(r_i \neq 0\), then \(\chi_{\mathfrak{r}}^{d, p} = 0\). In particular, the genus 0 Gromov-Witten invariant \(GW(X, d, pt, \ldots, pt)\) is even.

**Proof**: Let \(\mathfrak{r}(t) = (x_1(t), \ldots, x_{k_d}(t))\), \(t \in [0, 2\pi]\), be a loop of configurations of points of \(X\) such that \(x_2(t), \ldots, x_{k_d}(t)\) are fixed and \(x_{k_d}(t)\) defines a loop \(\gamma\) of \(\mathbb{R}X\) which is non-trivial.
against the first Stiefel-Whitney class of $\mathbb{R}X$. Equip $T_{x_{k_d}}(0)\mathbb{R}X$ with an orientation depending continuously on $t$, then the orientations of $T_{x_{k_d}}(0)\mathbb{R}X = T_{x_{k_d}}(2\pi)\mathbb{R}X$ are opposite. Thus $\chi_{k_d}^{d,p}(\mathbb{Z}(0)) = -\chi_{k_d}^{d,p}(\mathbb{Z}(2\pi))$. Now from Theorem 2.2 $\chi_{k_d}^{d,p}(\mathbb{Z}(0)) = \chi_{k_d}^{d,p}(\mathbb{Z}(2\pi))$. This forces the vanishing $\chi_{k_d}^{d,p} = 0$. □

Denote by $\mathcal{R}_d^+(\mathbb{Z})$ (resp. $\mathcal{R}_d^-(\mathbb{Z})$) the subset of $\mathcal{R}_d(\mathbb{Z})$ consisting of curves having positive (resp. negative) spinor state. Corollary 2.3 means that these two subsets have exactly same cardinality, they are mirror to each other. One example of such a manifold is the quadric in $\mathbb{C}P^4$ equipped with the real structure whose real part is non-orientable.

**Remark 2.4** 1) It is convenient to fix an orientation on orientable components of $\mathbb{R}X$ and to use it to define the integer $\chi_{k_d}^{d,p}$. When $k_d$ is even, the sign of $\chi_{k_d}^{d,p}$ depends on this choice of an orientation. We can then get rid of the necessity to put an orientation on $T_{x_{k_d}}\mathbb{R}X$. Indeed, for orientable components, it is given by their orientation and for non-orientable components, either $k_d$ is odd and the integer $\chi_{k_d}^{d,p}$ is anyway well defined, or $k_d$ is even and $\chi_{k_d}^{d,p} = 0$ from Corollary 2.3. Note that the pin structure $p$ together with the orientation induce then a spin structure on orientable components of $\mathbb{R}X$. From now on, every orientable components of $\mathbb{R}X$ will be equipped with a spin structure $s$, which is more convenient for our need. In case $\mathbb{R}X$ is orientable, the integer $\chi_{k_d}^{d,p}$ will be then rather denoted by $\chi_{k_d}^{d,s}$.

2) Such a vanishing result as the one given by Corollary 2.3 can also be given for curves in $\mathbb{C}P^3$ of even degree. Indeed, the integers $\chi_{r,s}^{d,s}(\mathbb{Z}_0)$ and $\chi_{r,s}^{d,s}(\mathbb{Z}_1)$ must then have opposite signs if $\mathbb{Z}_0$ and $\mathbb{Z}_1$ are images to each other under a real reflexion of $\mathbb{C}P^3$. This has just been noticed and communicated to me by G. Mikhalkin. Once more, this implies that the associated Gromov-Witten invariant is even in even degree. The first degree where the values of these invariants of the projective space are not known is thus 5. The associated Gromov-Witten invariant is then 105 (and 122129 in degree 7 as taken out from [4]). Note that similarly, the action of the group of real automorphisms of $X$ on the space of real configuration of points provides symmetries in the invariant $\chi^p$.

Thanks to this remark, we can define the polynomial $\chi^{d,p}(T) = \sum_{r,s \in \mathbb{Z}^n} \chi^{d,p}(T)^r \in \mathbb{Z}[T]$, where $T^r = T_1^{r_1} \cdots T_n^{r_n}$. This polynomial is of the same parity as the integer $k_d$ and each of its monomials actually only depends on one indeterminate. Theorem 2.2 means that the function $\chi^p : d \in H_2(X;\mathbb{Z}) \rightarrow \chi^{d,p}(T) \in \mathbb{Z}[T]$ is an invariant associated to the isomorphism class of the real algebraic convex 3-manifold $(X, c_X)$. As an application, this invariant provides the following lower bounds in real enumerative geometry.

**Corollary 2.5** Under the assumptions of Theorem 2.2, denote by $R_d(\mathbb{Z})$ the number of real irreducible rational curves passing through $\mathbb{Z}$ in the class $d$ and by $N_d$ the associated Gromov-Witten invariant. Then, $|\chi^{d,p}| \leq R_d(\mathbb{Z}) \leq N_d$. □

Note that a similar invariant and similar lower bounds have already been obtained in [4], [15] using real rational curves in real symplectic 4-manifolds. The question was then raised whether there exists such invariants in higher dimensions. The results presented here thus provide a partial answer to this question.

The following natural questions arise from Corollary 2.5. Are the upper and lower bounds given by this corollary sharps? How to compute the invariant $\chi_{r,s}^{d,p}$? See [13] for a discussion of related problems in real enumerative geometry and [5] for an estimation of the similar invariants constructed in [4], [15].
Finally, note that it is possible to understand the dependence of \( \chi_r^{d,p} \) with respect to \( r \), see \cite{12}.

Remark 2.6 G. Mikhalkin has just communicated to me that using considerations from tropical geometry, he is able to prove that in degree 4 in \( \mathbb{C}P^3 \), though the invariant \( \chi_S^{4,g} \) vanishes, the lower bound 0 given by Corollary 2.5 is sharp. This contrasts with the complex dimension 2, see \cite{5}.

3 Proof of Theorem 2.2

Let \( \tau \in S_{k_d} \) having \( \sum_{i=1}^n r_i \) fixed points in \( \{1, \ldots, k_d\} \) and such that \( \tau^2 = id \). Remember that \( ev_{k_d} : (\overline{M}_{0,k_d}(X), c_{\overline{M},\tau}) \to (X^{k_d}, c_{\tau}) \) is a real morphism between real algebraic varieties, see \cite{11}. Denote by \( \Re_{\tau}X^{k_d} \) (resp. \( \Re_{\tau}\overline{M}_{0,k_d}(X) \)) the real part of \( (X^{k_d}, c_{\tau}) \) (resp. \( (\overline{M}_{0,k_d}(X), c_{\overline{M},\tau}) \)) and by \( \Re_{\tau}ev_{k_d} \) the restriction of \( ev_{k_d} \) to \( \Re_{\tau}\overline{M}_{0,k_d}(X) \to \Re_{\tau}X^{k_d} \).

3.1 Genericy arguments

Proposition 3.1 Let \( X \) be a smooth algebraic convex 3-manifold and \( u_0 : \mathbb{C}P^1 \to X \) be a morphism having a unique cuspidal point at \( z_0 \in \mathbb{C}P^1 \). Assume that the holomorphic bundle \( u_0^*TX \otimes \mathcal{O}_{\mathbb{C}P^1}(-z_0) \) is generated by its global sections and denote by \( d = (u_0)_*[\mathbb{C}P^1] \in H_2(X; \mathbb{Z}) \). Then, the locus of non-immersed curves is a subvariety of codimension 2 of \( \mathcal{M}_{d,0}^d(X) \) in the neighborhood of \( u_0 \).

Proof:

Denote by \( T^* \) the holomorphic vector bundle of rank 3 over \( \mathcal{M}_{d,1}^d(X) \) whose fiber over \( (u, \mathbb{C}P^1, z) \in \mathcal{M}_{d,1}^d(X) \) is the vector space \( Hom(T_z\mathbb{C}P^1, T_{u(z)}X) \). This bundle is equipped with a tautological section \( \sigma : (u, \mathbb{C}P^1, z) \in \mathcal{M}_{d,1}^d(X) \mapsto d_zu \in Hom_\mathbb{C}(T_z\mathbb{C}P^1, T_{u(z)}X) \). The vanishing locus of \( \sigma \) coincide with the locus of curves \( (u, \mathbb{C}P^1, z) \in \mathcal{M}_{d,1}^d(X) \) having a cuspidal point at \( z \). Let us prove that \( \sigma \) vanishes transversely at the point \( (u_0, \mathbb{C}P^1, z_0) \). For this purpose, we fix some holomorphic local coordinates in the neighborhood of \( z_0 \in \mathbb{C}P^1 \) and in the neighborhood of \( u_0(z_0) \in X \). These coordinates induce a connection \( \nabla \) on the bundle \( u_0^*TX \) in the neighborhood of \( z_0 \), as well as a connection \( \nabla^{T^*} \) on the bundle \( T^* \) in the neighborhood of \( (u_0, \mathbb{C}P^1, z_0) \). Let \( \xi \in T_{z_0}\mathbb{C}P^1 \) and \( \zeta \in T_{u_0(z_0)}X \). By hypothesis, there exists a section \( v \) of the bundle \( u_0^*TX \) such that \( v(z_0) = 0 \) and \( \nabla v|_{z_0} = \xi^* \otimes \zeta \). Then, \( (v, z_0) \in T_{(u_0, \mathbb{C}P^1, z_0)}\mathcal{M}_{d,1}^d(X) \) and \( \nabla^{T^*}(v, z_0) = \xi^* \otimes \zeta \). Since \( \nabla^{T^*} \sigma|_{(u_0, \mathbb{C}P^1, z_0)} \) is surjective, the result follows.

Remark 3.2 1) Let \( X = \mathbb{C}P^1 \times \mathbb{C}P^2 \) and \( d = kl \) where \( k \geq 3 \) and \( l \) is the class of a line in a fiber \( \{z\} \times \mathbb{C}P^2 \) of \( X \). Then the locus of cuspidal curves is of codimension 1 in \( \mathcal{M}_{d,0}^d(X) \). However, if \( (u, \mathbb{C}P^1) \) is such a curve and \( z \in \mathbb{C}P^1 \) is a cuspidal point of \( u \), then the bundle \( u^*TX \otimes \mathcal{O}_{\mathbb{C}P^1}(-z) \) is not generated by its global sections.

2) Let \((u, \mathbb{C}P^1, z) \in \mathcal{M}_{d,0}^d(X) \) be such that \( \dim H^1(\mathbb{C}P^1; N_u \otimes \mathcal{O}_{\mathbb{C}P^1}(-z)) = 1 \). Then \( u \) has a unique cuspidal point \( z_0 \in \mathbb{C}P^1 \) and \( N_u \cong \mathcal{O}_{\mathbb{C}P^1}(k_d - 2) \oplus \mathcal{O}_{\mathbb{C}P^1}(k_d - 1) \). From the long exact sequence associated to the short exact sequence \( 0 \to T\mathbb{C}P^1 \to u^*TX \otimes \mathcal{O}_{\mathbb{C}P^1}(-z_0) \to N_u \otimes \mathcal{O}_{\mathbb{C}P^1}(-z_0) \to 0 \) we deduce that the bundle \( u^*TX \otimes \mathcal{O}_{\mathbb{C}P^1}(-z_0) \) is generated by its global sections.
sections as soon as \( k_d \geq 3 \). When \( k_d = 1 \), \( \mathcal{M}^{d}_{0,k_d}(X) \) does not contain any non-immersed curve since \( \deg(u^*TX) = 2 \), which implies that any morphism of sheaves \( T^*CP^1 \to u^*TX \) is injective. For \( k_d = 2 \), see the next remark.

3) Let \( A \) be a cuspidal cubic curve in \( \mathbb{C}P^2 \). Denote by \( Y \) the blown up of \( \mathbb{C}P^2 \) at 5 distinct points of \( A \) outside its cuspidal point and by \( \tilde{A} \) the strict transform of \( A \) in \( Y \). Then \( \tilde{A} \subset X = Y \times \mathbb{C}P^1 \) satisfies \( c_1(X)\tilde{A} = 4 \), but the locus of non-immersed curves of \( X \) in the class \([\tilde{A}]\) is of codimension one. In this case however, though \( H^1(\tilde{A};TX|_{\tilde{A}}) = 0 \), \( X \) is not convex.

The divisor \( \mathbb{R}_+K = \mathbb{R}_+M^d_{0,k_d}(X) \setminus \mathbb{R}_+M^d_{0,k_d}(X)^* \) is real and made of reducible or multiple curves. Denote by \( \mathbb{R}_+K_{reg} \) the locus of curves \((u,C,z)\in\mathbb{R}_+K\) such that \( C \) has two irreducible components \( C_1 \) and \( C_2 \) for which \( u(C_1), u(C_2) \) are real, immersed and meet in a single ordinary double point away from \( u(z) \), and which have one of these two properties:

- Either \( u(C_1), u(C_2) \) are both balanced and for \( i \in \{1,2\} \), \( z^i = C_i \cap z \) has cardinality \( \frac{1}{2}c_1(X)d_i \) where \( d_i = u_*(C_i) \in H_2(X;\mathbb{Z}) \).
- Or \( N_{u_1} \equiv O_{C_1}(k_{d_1} - 1) \oplus O_{C_1}(k_{d_1}) \) and \( N_{u_2} \equiv O_{C_2}(k_{d_2} - 2) \oplus O_{C_2}(k_{d_2} - 1) \) where \( k_{d_1} = E(\frac{1}{2}c_1(X)d_1), k_{d_2} = E(\frac{1}{2}c_1(X)d_2) + 1, u_1 = u|_{C_1} \) and \( u_2 = u|_{C_2} \). Moreover, \( z^i = C_i \cap z \) has cardinality \( k_d \) for \( i \in \{1,2\} \), and the tangent line to \( u(C_1) \) (resp. \( u(C_2) \)) at the point \( u(C_1) \cap u(C_2) \) is not mapped to the unique subline bundle of degree \( k_{d_2} - 1 \) (resp. \( k_{d_1} \)) of \( N_{u_2} \) (resp. \( N_{u_1} \)).

**Proposition 3.3** The image of the complement \( \mathbb{R}_+K \setminus \mathbb{R}_+K_{reg} \) under \( \mathbb{R}_+ev^d_{k_d} \) is of codimension at least two in \( \mathbb{R}_+X^{k_d} \).

**Proof:**

From Theorem 1.1, \( K \) is a divisor with normal crossings of \( \mathcal{M}^d_{0,k_d}(X) \). As a consequence, the locus of curves having more than two irreducible components or meeting in more than one single ordinary double point is of codimension at least two in \( \mathcal{M}^d_{0,k_d}(X) \). It suffices then to prove the result for curves \((u,C,z)\) such that \( C \) has two irreducible components \( C_1 \) and \( C_2 \) for which \( u(C_1), u(C_2) \) meet in a single ordinary double point away from \( u(z) \). For \( i \in \{1,2\} \), denote by \( z^i = C_i \cap z \), \( d_i = u_*(C_i) \in H_2(X;\mathbb{Z}) \) and \( k_{d_i} = \# z^i \). The morphism \( ev^d_{k_d} \) restricted to these curves is the composition of the restriction morphism \((u,C,z)\in K \mapsto ((u_1,C_1,z^1),(u_2,C_2,z^2)) \in \mathcal{M}^d_{0,k_{d_1}}(X) \times \mathcal{M}^d_{0,k_{d_2}}(X) \) and of the evaluation morphism \( ev^d_{k_{d_1}} \times ev^d_{k_{d_2}} : \mathcal{M}^d_{0,k_{d_1}}(X) \times \mathcal{M}^d_{0,k_{d_2}}(X) \to X^{k_d} \). Two cases are now to be considered depending on whether \( c_1(X)d_i \) is even or odd. In the first case, we can assume that \( k_{d_1} = \frac{1}{2}c_1(X)d_1 \).

Indeed, if \( k_{d_1} > \frac{1}{2}c_1(X)d_1 \) for example, then \( \dim(\mathcal{M}^d_{0,k_{d_1}}(X)) = c_1(X)d_1 + k_{d_1} - 3k_{d_1} - 2 = \dim(X^{k_d}) - 2 \) so that already the image of \( ev^d_{k_{d_1}} \times ev^d_{k_{d_2}} \) is of codimension 2 in \( X^{k_d} \). For the same reason, from Lemma 1.2, we can assume that at least one of the two curves \( u(C_1), u(C_2) \), say \( u(C_1) \), is balanced. Note that perturbing the \( k_{d_1} \) points \( u(z^1) \) in \( X^{k_{d_1}},u \) we can deform \( u(C_1) \) in order to separate it from \( u(C_2) \). It follows that the image of the restriction morphism \( K \to \mathcal{M}^d_{0,k_{d_1}}(X) \times \mathcal{M}^d_{0,k_{d_2}}(X) \) is of codimension at least one in \( \mathcal{M}^d_{0,k_{d_1}}(X) \times \mathcal{M}^d_{0,k_{d_2}}(X) \). Moreover, from Lemma 1.2, the image of non-balanced curves of \( \mathcal{M}^d_{0,k_{d_2}}(X) \) under \( ev^d_{k_{d_2}} \) is of codimension at least 1 in \( X^{k_{d_2}} \). It follows from these two remarks that we can also assume that \( u(C_2) \) is balanced. The only remaining thing to prove in this first case is that we can
assume that both $u(C_1)$ and $u(C_2)$ are real. If this would not be the case, they would be exchanged by the involution $c_X$. They would then meet at each real point in the configuration $x$. By hypothesis, there exists such real points. Now since the condition to have a marked point at the intersection point $C_1 \cap C_2$ is of codimension 2 in $\overline{M}_{0,k_d}(X)$, it creates a “ghost” component, we are done.

In the second case, we can for the same reason assume that $k_{d_1} = E(\frac{1}{2}C_1(X)d_1)$, $k_{d_2} = E(\frac{1}{2}C_1(X)d_2) + 1$ and then that $N_{u_1} \cong O_{C_1}(k_{d_1} - 1) \oplus O_{C_1}(k_{d_1})$ and $N_{u_2} \cong O_{C_2}(k_{d_2} - 2) \oplus O_{C_2}(k_{d_2} - 1)$. Moreover, we can assume that both $u(C_1)$ and $u(C_2)$ are real. Finally, the condition on the tangent line of $u(C_1)$ (resp. of $u(C_2)$) at the point $u(C_1) \cap u(C_2)$ can be obtained by perturbation of the configuration of points $u(z^1)$ and $u(z^2)$ in $X^{k_{d_1}}$ and $X^{k_{d_2}}$. It follows that the locus of curves which do not have all these properties is of codimension at least two in $\overline{M}_{0,k_d}(X)$. Hence the result. □

3.2 Proof of Theorem 2.2

Let $\underline{x}^0, \underline{x}^1 \in \mathbb{R}_r X^{k_d}$ be two regular values of $\mathbb{R}_r ev_{k_d}^d$ which belong to the same connected component of $\mathbb{R}_r X^{k_d}$ outside the divisor $\mathbb{R} D_{reg} = \mathbb{R}_r ev_{k_d}^d(\mathbb{R}_r K_{reg})$. We have to prove that $\chi^{d,p}(\underline{x}^0) = \chi^{d,p}(\underline{x}^1)$. Let $\gamma : [0, 1] \to \mathbb{R}_r X^{k_d}$ be a generic piecewise analytic path joining $\underline{x}^0$ to $\underline{x}^1$ and transversal to $\mathbb{R}_r ev_{k_d}^d$. Denote by $\mathbb{R} M_{\gamma}$ the fiber product $\mathbb{R}_r \overline{M}_{0,k_d}(X) \times \gamma [0, 1]$ and by $\mathbb{R} \pi_{\gamma}$ the associated projection $\mathbb{R} M_{\gamma} \to [0, 1]$. The integer $\chi^{d,p}(\gamma(t))$ is well defined for every $t \in [0, 1]$ but a finite number of parameters $0 < t_0 < \cdots < t_j < 1$ corresponding either to critical values of $\mathbb{R} \pi_{\gamma}$, or to the crossing of the wall $\mathbb{R} D_{reg} = \mathbb{R}_r ev_{k_d}^d(\mathbb{R}_r K_{reg})$. We can assume that the latter is crossed transversely by $\gamma$. Note also that from Lemma 3.2 and Proposition 3.1 critical points of $\mathbb{R} \pi_{\gamma}$ correspond to immersed irreducible curves $(u, C, z)$ with normal bundle isomorphic to $O_C(k_d - 2) \oplus O_C(k_d)$.

Lemma 3.4 The path $\gamma$ can be chosen such that when it crosses the wall of critical values of $\mathbb{R} \pi_{\gamma}$, only one real point $x_i(t)$ of $\gamma(t) = (x_1(t), \ldots, x_{k_d}(t))$ depends on $t$. Similarly, it can be chosen such that when it crosses the wall $\mathbb{R} D_{reg}$, either only one real point of $\gamma(t)$ depends on $t$, or only two points exchanged by $c_X$ depend on $t$. In the last case, this choice can be done such that in addition to the $k_d - 2$ constant points of $\gamma$, the corresponding family of curves in $\mathbb{R} M_{\gamma}$ has a common fixed real point in $\mathbb{R} X$.

Proof:

Let $(u, C, z)$, $C = C_1 \cup C_2$, be a stable map in $\mathbb{R}_r K_{reg}$. The tangent space to $\mathbb{R} D_{reg}$ at the point $u(z)$ consists of infinitesimal deformations of $u(z)$ for which $u(C)$ deforms into a reducible connected curve passing through this configuration of points. From Proposition 3.3 two cases are then to be considered. If $(u_1, C_1, z^1)$ and $(u_2, C_2, z^2)$ are balanced, where $z^1 = z \cap C_1$ and $u_i = u|_{C_i}$, we can assume that $u(C_2)$ has a real point in the configuration $u(z)$, say $u(z_{k_d})$. There exists then a real section $v_2$ of the normal bundle $N_{u_2}$ which vanishes at every point of $z^2$ except $z_{k_d}$ and which at the point $u(C_1) \cap u(C_2)$ does not belong to the image of the tangent line of $u(C_1)$ in $N_{u_2}$. Then, the infinitesimal deformation of $u(z_{k_d})$ in the direction $v_2(z_{k_d})$, the other points $u(z_1), \ldots, u(z_{k_d-1})$ being fixed, provides a vector transversal to $\mathbb{R} D_{reg}$ at the point $u(z)$. This proves the lemma in this case.

Assume now that $N_{u_1} \cong O_{C_1}(k_{d_1} - 1) \oplus O_{C_1}(k_{d_1})$ and $N_{u_2} \cong O_{C_2}(k_{d_2} - 2) \oplus O_{C_2}(k_{d_2} - 1)$, where $k_{d_i} = \#(z^i)$. If $u(z^2)$ has a real point, say $u(z_{k_d})$, then it suffices to deform $u(z_{k_d})$ in a real direction which does not project onto a fiber of the unique subline bundle of degree
$k_{d_2} - 1$ of $N_{u_2}$, the other points $u(z_1), \ldots, u(z_{k_{d_2}-1})$ being fixed, to define an infinitesimal deformation of $u(z)$ transversal to $\mathbb{R}D_{reg}$. Otherwise, $u(z^2)$ has at least two points exchanged by $c_X$, say $u(z_{k_d-1})$ and $u(z_{k_d})$. Choose two distinct real points $z'_d$ and $z''_d$ in the real part of $C_2 \setminus z^2$, and denote by $z' = (z_1, \ldots, z_{k_d-2}, z'_d, z''_d)$. Then $(u, C, z') \in \mathbb{R}^d_{K_{reg}}$, where $\tau' = \tau \circ (k_d - 1_k_d)$. Let $(u_t, C_t, z(t)) \in \mathbb{R}^d_{\mathbb{R}_{M_0, k_d}}(X)$ be a path transversal to $\mathbb{R}^d_{K_{reg}}$, such that only $u_t(z'_{k_d}(t))$ depends on $t$. Such a path exists from what we have already done. Choose a deformation $z_{k_d-1}(t), z_k(t)$ of the points $z_{k_d-1}, z_k$ of $C_0 = C$ such that $u_t(z_{k_d-1}(t))$ and $u_t(z_k(t))$ are exchanged by $c_X$. Then the path $(u_t, C_t, z(t)) \in \mathbb{R}^d_{\mathbb{R}_{M_0, k_d}}(X)$, where $z(t) = (z_1(t), \ldots, z_{k_d}(t))$, is transversal to $\mathbb{R}^d_{K_{reg}}$ at the point $(u, C, z)$. Moreover, only the points $u_t(z_{k_d-1}(t))$ and $u_t(z_k(t))$ depend on $t$, and the curves $u_t(C_t)$ have an additional real fixed point, namely $u_t(z'_d(t))$. The lemma is thus proved in this case.

Finally, assume that $(u, C, z)$ is a critical point of $\mathbb{R}^d_{\pi_{\gamma}}$ and that $u(z_{k_d})$ is real. Then $N_u \cong O_C(k_d - 2) \oplus O_C(k_d)$. Choose any infinitesimal deformation of $u(z)$ which fixes $u(z_1), \ldots, u(z_{k_d-1})$ and deforms $u(z_{k_d})$ in a real direction different from the one given by the unique subline bundle of degree $k_d$ of $N_u$. This deformation is transversal to the wall of critical values of $\mathbb{R}^d_{ev_{k_d}}$. Hence the result. $\square$

**Proof of Theorem 2.2:**

Choose a path $\gamma$ given by Lemma 2.1. We have to prove that the value of the integer $\chi^d_r(\gamma(t))$ does not change when $t$ crosses the parameters $t_0 < \cdots < t_j$. When this parameter corresponds to a critical value of $\mathbb{R}^d_{\pi_{\gamma}}$, this is given by the following Proposition 3.5. When this parameter corresponds to the crossing of the wall $\mathbb{R}^d_{D_{reg}}$, this is given by the following Proposition 3.7. $\square$

**Proposition 3.5** Let $(u, C, z) \in \mathbb{R}^d_M$ be a critical point of $\mathbb{R}^d_{\pi_{\gamma}}$, $l_0 \in \mathbb{N}^*$ be the vanishing order of $d((u, C, z))\mathbb{R}^d_{\pi_{\gamma}}$ and $t_0 = \mathbb{R}^d_{\pi_{\gamma}}(u, C, z) \in [0, 1]$. Then, there exists $\eta > 0$ and a neighborhood $W_0$ of $(u, C, z)$ in $\mathbb{R}^d_M$ such that the following alternative occurs:

1) Either $l_0$ is odd, then for every $t \in ]t_0 - \eta, t_0[, W_0 \cap \mathbb{R}^d_{\pi_{\gamma}}(t) = \{(u^+_t, C^+_t, z^+_t), (u^-_t, C^-_t, z^-_t)\}$ with $sp(u^+_t(C^+_t)) = -sp(u^-_t(C^-_t))$ and for every $t \in ]t_0, t_0 + \eta[, W_0 \cap \mathbb{R}^d_{\pi_{\gamma}}(t) = \emptyset$, or the converse.

2) Or $l_0$ is even, then for every $t \in ]t_0 - \eta, t_0 + \eta[, W_0 \cap \mathbb{R}^d_{\pi_{\gamma}}(t) = \{(u_t, C_t, z_t)\}$ and $sp(u_t(C_t))$ does not depend on $t \neq t_0$.

**Proof:**

Let us complexify the path $\gamma$ in the neighborhood of $t_0 \in [0, 1]$ in order to get an analytic path $\gamma_C : t \in \Delta_{t_0}(\eta) = \{z \in \mathbb{C} \mid |z - t_0| < \eta\} \rightarrow X^{k_2}$ such that for every $t \in \Delta_{t_0}(\eta)$, $\gamma_{\mathbb{C}}(t) = c_{\mathbb{C}} \circ \gamma_C(t)$ and $\gamma_{\mathbb{C}}|_{t_0 - \eta, t_0 + \eta} = \gamma$. Denote then by $\mathcal{M}_{\gamma}$ the fiber product $\mathcal{M}_{0, k_{d}}(X) \times \gamma [0, 1]$ and by $p_{\gamma}$ the associated projection $\mathcal{M}_{\gamma} \rightarrow \Delta_{t_0}(\eta)$. Denote also by $U \rightarrow \mathcal{M}_{\gamma}$ the restriction of $\mathcal{M}_{0, k_{d}}(X) \rightarrow \mathcal{M}_{0, k_{d}}(X)^\ast$. Hence, $U$ is a ruled surface over the smooth curve $\mathcal{M}_{\gamma}$. Denote by $c_{\mathbb{C}}$ and $c_{\mathbb{P}}$ the real structures on $\mathcal{M}_{\gamma}$ and $U$, so that the submersion $U \rightarrow \mathcal{M}_{\gamma}$ is $\mathbb{Z}/2\mathbb{Z}$-equivariant. Fix a real parametrization $\lambda \in \Delta \rightarrow (u_{\lambda}, C_{\lambda}, z_{\lambda}) \in \mathcal{M}_{\gamma}$ so that the projection $\mathcal{M}_{\gamma} \rightarrow \Delta_{t_0}(\eta)$ writes $\lambda \in \Delta \mapsto \eta \lambda_{0+1} + t_0$. Denote then by $N$ the holomorphic rank two vector bundle over $U$ whose fiber over $C_{\lambda}$ is the normal bundle $N_{u_\lambda}$. For $\lambda \neq 0$, we have $N_{u_{\lambda}} \cong O_{C_{\lambda}}(k_{d_2} - 1) \oplus O_{C_{\lambda}}(k_{d_2} - 1)$ and for $\lambda = 0$, $N_{u_0} \cong O_{C_{0}}(k_{d_2} - 2) \oplus O_{C_{0}}(k_{d_2})$. Thus, the projectivization $P(N)$ is a deformation of ruled surfaces over the disk $\Delta$ such that the fibers $P(N_{u_{\lambda}})$ over $\lambda \in \Delta \setminus \{0\}$ are isomorphic to $\mathbb{C}P^1 \times \mathbb{C}P^1$ and the fiber $P(N_{u_0})$ is isomorphic to the
ruled surface $P(\mathcal{O}_{\mathbb{C}P^1} \oplus \mathcal{O}_{\mathbb{C}P^1}(2))$. The path $\gamma_\mathbb{C}$ can be written $(x_1(t), \ldots, x_k(t))$ where only the last point $x_k(t) \in \mathbb{R}X$ depends on $t$ and $x_k(t)$ is never tangent to a rational curve of $M_\mathbb{C}$.

It follows that each ruled surface $P(N_{\mathbb{C}k})$ has a marked point $w_0$ which is the projectivization of the complex line generated by $x_k'(t_{\lambda}) \in N_{\mathbb{C}k}$, for $t_{\lambda} = \eta \lambda^{\nu_0+1} + t_0$. Since $\gamma_\mathbb{C}$ is transversal to the wall of critical values of $ev^1_{\mathbb{C}k}$, $w_0$ does not belong to the exceptional section of $P(N_{\mathbb{C}0})$.

Let $h_0$ be a real section of $P(N_{\mathbb{R}0})$ disjoint from the exceptional section and passing through $w_0$. This section can be deformed into an analytic family $(h_\lambda)_{\lambda \in \Delta}$ of sections of $P(N_{\mathbb{R}k})$ such that $h_\lambda$ passes through $w_\lambda$, $h_\lambda = h_\lambda$ and $h_\lambda$ is of bidegree $(1,1)$ in $P(N_{\mathbb{R}k})$ for $\lambda \neq 0$. Denote by $L_{\lambda} \subset N_{\mathbb{R}k}$ the subline bundle associated to $h_\lambda$ and by $M_{\lambda} = N_{\mathbb{R}k}/L_{\lambda}$. We have $\text{deg}(L_{\lambda}) = k_d - 2$ and $\text{deg}(M_{\lambda}) = k_d$. Moreover, the extension $0 \to L_{\lambda} \to N_{\mathbb{R}k} \to M_{\lambda} \to 0$ is non-trivial for $\lambda \neq 0$ and trivial for $\lambda = 0$. Fix an identification $U \cong \Delta \times \mathbb{C}P^1$ such that $z^\lambda$ is constant and let $\delta$ be a real generator of $H^1(\mathbb{C}P^1; \mathcal{O}_{\mathbb{C}P^1}(-2))$. There exists a holomorphic function $f : \Delta \to \mathbb{C}$ such that the extension class of $0 \to L_{\lambda} \to N_{\mathbb{R}k} \to M_{\lambda} \to 0$ is $f(\lambda)\delta \in H^1(\mathbb{C}P^1; M^\lambda_{\lambda} \otimes L_{\lambda}) = H^1(\mathbb{C}P^1; \mathcal{O}_{\mathbb{C}P^1}(-2))$. Then, $f(0) = 0$, $f(\lambda) \neq 0$ if $\lambda \neq 0$ and we define $i_f \in \mathbb{N}^+ \setminus \{0\}$ to be the vanishing order of $f$ at 0. Let $V_0, V_1$ be the two standard affine charts of $\mathbb{C}P^1$, chosen such that $z^\lambda_{k_d}(t_0)$ belongs to $V_0$. The deformation $N$ is then obtained as the gluing of the trivializations $V_0 = \Delta \times V_1 \times \mathcal{O}_{\mathbb{C}P^1}(k_d - 2) \oplus \mathcal{O}_{\mathbb{C}P^1}(k_d)$ and $V_1 = \Delta \times V_1 \times \mathcal{O}_{\mathbb{C}P^1}(k_d - 2) \oplus \mathcal{O}_{\mathbb{C}P^1}(k_d)$ with gluing maps:

$$(\lambda, z, (s_1, s_2)) \in V_0 \cap V_1 \mapsto (\lambda, z, (s_1 + f(t)\delta s_2)) \in V_1 \cap V_0.$$  

Now, note that the bundle $N$ has a tautological section $v^\lambda = \frac{d}{dz}u_\lambda$. This section vanishes at the fixed points $z^\lambda_1, \ldots, z^\lambda_{k_d-1}$. Denote its coordinates in the trivialization $V_0$ by $v^\lambda(z) = (\lambda, z, (s^\lambda_1(z), s^\lambda_2(z)))$. Since $(u_0, C_0, 0)$ is a critical point of $\pi_\gamma$, from Lemma 12, $v_0$ defines a non-zero element of $H^0(C_0; N_{\mathbb{R}0} \otimes \mathcal{O}_{\mathbb{C}0}(-z_0)) = H^0(\mathbb{C}P^1; \mathcal{O}_{\mathbb{C}P^1}(-2) \oplus \mathcal{O}_{\mathbb{C}P^1})$. It follows that the component $s^\lambda_0$ of $v^\lambda$ vanishes. Let us prove that the vanishing order of $s^\lambda_0(z_{k_d})$ at $\lambda = 0$ is $i_f$. Indeed, in the Taylor expansion of $s^\lambda_0$ all the terms of order less than $i_f$ define sections of $L_{\lambda}$ which vanish at the points $z^\lambda_1, \ldots, z^\lambda_{k_d-1}$. These are thus the zero section. Denote by $(s_1)^{(l_f)}$ (resp. $(s_2)^{(0)}$) the term of order $l_f$ (resp. 0) in the Taylor expansion of $s^\lambda_1$ (resp. $s^\lambda_2$). Then the triple $(\lambda, z, ((s_1)^{(l_f)})(z_{k_d}), (s_2)^{(0)}(z_{k_d}))$ defines a section of the bundle $N$. If $(s_1)^{(l_f)}(z_{k_d}) = 0$, then this section vanishes at the $k_d$ points $z_1, \ldots, z_{k_d}$. Since when $\lambda \neq 0$, $N_{\mathbb{R}k} \cong C_{\lambda}(k_d - 1) \oplus C_{\lambda}(k_d - 1)$, this is impossible and thus the vanishing order of $s^\lambda_0(z_{k_d})$ at $\lambda = 0$ is exactly $i_f$. Note that since by construction $L_{\lambda}$ contains $x_k'(t_{\lambda})$, where $t_{\lambda} = \eta \lambda^{\nu_0+1} + t_0$, the second component $s^\lambda_2$ is identically zero at the point $z^\lambda_{k_d}$. From $\pi_\gamma(u_\lambda, C_\lambda, z^\lambda) = u_\lambda(z^\lambda)$, we deduce that $d|_{(u_\lambda, C_\lambda, z^\lambda)\pi_\gamma(v_\lambda)} = v_\lambda(z^\lambda) = (0, \ldots, 0, v_\lambda(z^\lambda_{k_d}))$. Hence the vanishing order $l_0$ of $d|_{(u, C, z)\pi_\gamma}$ is the one of $s^\lambda_0(z_{k_d})$ at the point $\lambda = 0$, that is $i_f$.

Now, fix an orientation of the curves $\mathbb{R}C_\lambda, \lambda \in [-1,1]$, and denote by $[\mathbb{R}v_\lambda]$ the section of $P(\mathbb{R}N_{\mathbb{C}k})$ associated to the line bundle generated by $v_\lambda$. The latter is equipped with the orientation induced by the one of $\mathbb{R}C_\lambda$. Note that it is the real part of a section of $P(N_{\mathbb{C}k})$ with self-intersection zero, since the holomorphic line bundle generated by $v_\lambda$ has degree $k_d - 1$. Similarly, the real rank two vector bundle $\mathbb{R}N_{\mathbb{C}k}$ has an orientation induced by the ones of $\mathbb{R}C_\lambda$ and $T_{x_k}\mathbb{R}X$. Let $f_\lambda$ be a fiber of $P(\mathbb{R}N_{\mathbb{C}k})$ equipped with the orientation induced by the one of $\mathbb{R}N_{\mathbb{C}k}$. Then, for $\lambda \neq 0$, $([\mathbb{R}v_\lambda], f_\lambda)$ provides a basis of the lattice $H_1(P(\mathbb{R}N_{\mathbb{C}k}); \mathbb{Z})$. The section $\mathbb{R}h_\lambda = P(\mathbb{R}L_{\lambda})$ has bidegree $(1,1)$. Let $\epsilon \in \{+1\}$ be such that for $\lambda < 0$, $[\mathbb{R}h_\lambda] = [\mathbb{R}v_\lambda] + \epsilon f_\lambda \in H_1(P(\mathbb{R}N_{\mathbb{C}k}); \mathbb{Z})$. Then, for $\lambda > 0$, $[\mathbb{R}h_\lambda] = [\mathbb{R}v_\lambda] - (-1)^{i_f} f_\lambda \in H_1(P(\mathbb{R}N_{\mathbb{C}k}); \mathbb{Z})$. This follows from the local expression of $v_\lambda$ in the neighborhood of $z^\lambda_{k_d}$, which is of the form
From Lemma 3.4, the family $\eta > 0$ there exists the restriction $T$ of the fiber $D$. Remove a small disk $l$. It follows that if $t_0 = t_f$ is even, the spinor states of $(u_\lambda, C_\lambda, z^\lambda)$ and $(u_{-\lambda}, C_{-\lambda}, z^{-\lambda})$ coincide for every $\lambda \neq 0$, whereas they are opposite when $t_0 = t_f$ is odd. Indeed, in this last case, the homotopy classes of the loops of the bundle $RX$ of orthonormal frames that we construct in order to compute the spinor state (see §22) exactly differ from the class of a non-trivial loop in a fiber of $RX$. The result now follows from the fact that the projection $\pi_{\gamma}$ has been identified in the neighborhood of $(u, C, z) \in \mathbb{R}M_\gamma$ with the map $\lambda \in [-1, 1] \mapsto \eta^{|t_0+1|} + t_0 \in [t_0 - \eta, t_0 + \eta]$. □

**Remark 3.6** From the proof of Proposition 3.5 arise the following question. Are the generic critical points of the evaluation map $ev_{k_d}^d : M_{0,k_d}(X) \to X^{k_d}$ non-degenerate when $X$ is convex, e.g. when $X = \mathbb{C}P^3$?

**Proposition 3.7** Let $(u, C, z) \in \mathbb{R}M_\gamma$ be such that $C$ is reducible and $t_1 = \mathbb{R}\pi_{\gamma}(u, C, z) \in [0, 1]$. Then, there exists $\eta > 0$ and a neighborhood $W_1$ of $(u, C, z)$ in $\mathbb{R}M_\gamma$ such that for every $t \in [t_1 - \eta, t_1 + \eta]$, $W_1 \cap \mathbb{R}\pi_{\gamma}^{-1}(t) = \{(u_t, C_t, z_t)\}$. Moreover, $sp(u_t(C_t))$ does not depend on $t \neq t_1$.

**Proof**:

From Propositions 3.5 and the choice of $\gamma$, $(u, C, z)$ is a regular point of $\mathbb{R}\pi_{\gamma}$. Thus there exists $\eta > 0$ and a neighborhood $W_1$ of $(u, C, z)$ in $\mathbb{R}M_\gamma$ such that for every $t \in [t_1 - \eta, t_1 + \eta]$, $W_1 \cap \mathbb{R}\pi_{\gamma}^{-1}(t) = \{(u_t, C_t, z_t)\}$. Denote by $U \to W_1$ the universal curve, it has a unique singular fiber over $t = t_1$. The real part $\mathbb{R}U$ is thus homeomorphic to a cylinder $Cyl$ blown up at one point, that is to the connected sum of a cylinder and a Moebius strip. From Lemma 3.4 the family $u_t(C_t)$ passes through $k_d - 1$ fixed points. For every $t \neq t_1$, the restriction $T\mathbb{R}U|_{RC_t}$ projects onto a subline bundle of the normal bundle of $RC_t$ in $RX$ which is the real part of a holomorphic line bundle of degree $k_d - 1$. Assume that $k_d$ is odd, so that this line bundle can be used in order to compute the spinor state of $RC_t$, $t \neq t_1$. The case $k_d$ even will follow along the same lines. Fix a continuous family $(e_1^t(z), e_2^t(z), t \neq t_1, z \in RC_t)$ of orthonormal frames of the tangent space at $u_t(z)$ of the image of $\mathbb{R}U$ in $RX$. This family is completed in a family $(e_1(z), e_2(z), e_3(z))$ of orthonormal frames of $Tu_t(z)RX$. Remove a small disk $D$ around the blown up point of $Cyl$. In $H_1(Cyl \setminus D; \mathbb{Z}/2\mathbb{Z})$, the class of the fiber $[RC_{t_1+n}]$ equals the sum of the class of the fiber $[RC_{t_1-n}]$ and the class of the boundary $\partial D$. Equip these loops with a family of orthonormal frames of $T\mathbb{R}X$ as before and denote by $p(RC_t)$ and $p(\partial D)$ the loops of $RX$ thus obtained. These loops are related by $p(RC_{t_1+n}) = p(RC_{t_1-n}) + p(\partial D) + p_0 \in H_1(RX; \mathbb{Z}/2\mathbb{Z})$, where $p_0$ is a non-trivial loop in $\mathbb{R}C_{t_1+n}$. $z \in \mathbb{R}C_{t_1+n} \leftrightarrow (\lambda^{l_1}, z)$, whereas the classes $[R\lambda_{t_1}]$ and $f_{t_1}$ continuously depend on $\lambda \in [-1, 1]$.
fiber of $R_X$. This is suggested by the following picture.

Assume now that $\mathbb{R}X$ is orientable, or that if $C_1, C_2$ denote the two components of $C$, then the curves $(u|_{C_1}, C_1, z \cap C_1)$ and $(u|_{C_2}, C_2, z \cap C_2)$ are balanced. In the Moebius strip that is glued instead of the disk $D$, the boundary $\partial D$ is homologous to two times the core $A$ of the Moebius strip. Denote by $p(A)$ a loop in $R_X$ obtained by equipping every point $z \in A$ with an orthonormal frame $(e_1(z), e_2(z), e_3(z))$ of $T_{u(t)}\mathbb{R}X$, such that $e_1(z) \in T_z A$ and $(e_1(z), e_2(z))$ generates the tangent space of the Moebius strip at $z$ except in a neighborhood of a point $z_0 \in A$ where $(e_1(z), e_2(z), e_3(z))$ does a half twist around the axis $TA$ (which is necessary since the Moebius strip is not orientable). Then, one observes the relation $p(\partial D) = 2p(A) + p_0 \in H_1(R_X; \mathbb{Z}/2\mathbb{Z})$.

We finally deduce that $p(\mathbb{R}C_{t_1+\eta}) = p(\mathbb{R}C_{t_1-\eta}) \in H_1(R_X; \mathbb{Z}/2\mathbb{Z})$, so that $sp(u_{t_1+\eta}(C_{t_1+\eta})) = sp(u_{t_1-\eta}(C_{t_1-\eta}))$.

It remains to consider the case when $\mathbb{R}X$ is not orientable and the curves $(u|_{C_1}, C_1, z \cap C_1)$ and $(u|_{C_2}, C_2, z \cap C_2)$ are not balanced. In this case, the double cover of orientations $\mathbb{R}X \to \mathbb{R}X$ is non-trivial over $A_1 = u(\mathbb{R}C_1)$ and $A_2 = u(\mathbb{R}C_2)$. Denote by $\tilde{A}_1$ and $\tilde{A}_2$ the lifts of $A_1$ and $A_2$ in $\mathbb{R}X$. These are two immersed circles in $\mathbb{R}X$ which intersects in two ordinary double points $a_1$ and $a_2$. These points divide $\tilde{A}_1$ (resp. $\tilde{A}_2$) in two connected components $\tilde{A}_1^+$ and $\tilde{A}_1^-$ (resp. $\tilde{A}_2^+$ and $\tilde{A}_2^-$). Let $\tilde{x}_{k_d}$ be the lift of $x_{k_d}$ in $\mathbb{R}X$ given by the choice of an orientation on $T_{x_{k_d}}\mathbb{R}X$. For $t \neq t_1$ in the neighborhood of $t_1$, denote by $\mathbb{R}C_t$ the unique lift of $u(\mathbb{R}C_t)$ in $\mathbb{R}X$ which passes through $\tilde{x}_{k_d}$. Without loss of generality, we can assume that $\tilde{x}_{k_d} \in \tilde{A}_1^+$ and that for $t_+ \in ]t_1, t_1 + \eta[$ (resp. $t_- \in ]t_1 - \eta, t_1[$), $\mathbb{R}C_{t_+}$ is in the neighborhood of $\tilde{A}_1^+ \cup \tilde{A}_2^-$ (resp. $\tilde{A}_1^+ \cup \tilde{A}_2^-$). Denote by $p(\mathbb{R}C_{t_+})$ the loop of $R_X$ obtained by equipping the curve $\mathbb{R}C_{t_+}$ with a family of direct orthonormal frames $(e_1(z), e_2(z), e_3(z))_{z \in \mathbb{R}C_{t_+}}$ as before. Then, the difference $\lim_{t_+ \to t_1} p(\mathbb{R}C_{t_+}) - \lim_{t_- \to t_1} p(\mathbb{R}C_{t_-})$ is observed to be a loop of $R_X$ over $\tilde{A}_2$ which is invariant under the involution $inv_R : (e_1, e_2, e_3) \in R_X | x \mapsto (d_{x \text{ inv}(e_1)}, d_{x \text{ inv}(e_2)}, -d_{x \text{ inv}(e_3)}) \in R_X|_{inv(x)}$ where $inv$ is the involution of the covering $\mathbb{R}X \to \mathbb{R}X$. Indeed, its restrictions
4 A study of the polynomial $\chi^{d,g}$

As was done in [15], it is possible to understand how the invariant $\chi_r^{d,g}$ depends on the $n$-tuple $r$ in terms of a new invariant. The aim of this last paragraph is to explain this phenomenon in the case of $(X, c_X) = (\mathbb{CP}^3, \text{conj})$.

4.1 Invariants of the blown up projective space

4.1.1 Statement of the results

Let $(Y, c_Y)$ be the real algebraic 3-manifold obtained after blowing up a real point $x_0$ of $(\mathbb{CP}^3, \text{conj})$. Denote by $Exc \subset Y$ the exceptional divisor of the blow up, $l \subset Exc \cong \mathbb{CP}^2$ the class of a line and $f \subset Y$ the strict transform of a line in $\mathbb{CP}^3$ passing through $x_0$. The cone $NE(Y)$ of effective curves of $Y$ is of dimension 2, closed and generated by $l$ and $f$. Note that $Y$ is not convex. Indeed, if $u: \mathbb{CP}^1 \to Y$ has an image contained in $Exc$ which is not a line, then $H^1(\mathbb{CP}^1; u^*TY) \neq 0$. Note also that if $A \subset Y$ is an irreducible curve not contained in $Exc$, then $A$ is equivalent to $af + bl$ with $0 \leq b \leq a$, since $0 \leq A.\text{Exc} = a - b$.

Let $0 \leq k \leq d$ and $dy = d(f + l) - kl$, so that $c_1(Y).dY = 4d - 2k$. Denote by $k_{dy} = 2d - k$. Let $y \subset Y^{k_{dy}}$ be a generic real configuration of $k_{dy}$ distinct points of $Y$, and $r$ be the number of real points in this configuration which is assumed to be non-zero. There are then only finitely many connected rational curves in $Y$ passing through $y$ in the homology class $dY$. Moreover,
these curves are all irreducible and balanced and their number does not depend on the generic choice of \( y \), it is equal to the genus 0 Gromov-Witten invariant \( N_{d_Y} = GW(Y, d_Y, pt, \ldots, pt) \) (see [3]). Denote by \( R_{d_Y}(y) \) the subset of these curves which are real and by \( R_{d_Y}(y) \) its cardinality. Equip \( \mathbb{R}Y = \mathbb{R}P^3 \# \mathbb{R}P^3 \) with a spin structure \( s_Y \). This spin structure allows us to define a spinor state for each real curve \( A \in R_{d_Y}(y) \), as in [2.2]. Put then:

\[
\chi^{d_Y, s_Y}_r(y) = \sum_{A \in R_{d_Y}(y)} sp(A) \in \mathbb{Z}.
\]

**Theorem 4.1** Let \((Y, c_Y)\) be the blown up of \( \mathbb{C}P^3, \text{conj} \) at a real point \( x_0 \) and \( s_Y \) be a spin structure on \( \mathbb{R}Y \). Let \( 0 \leq k \leq d \), \( d_Y = d(f + l) - kl \) and \( k_{d_Y} = 2d - k \). Let \( y \) be a generic real configuration of \( k_{d_Y} \) distinct points of \( Y \) such that \( r = \#(y \cap \mathbb{R}Y) \) does not vanish. Then the integer \( \chi^{d_Y, s_Y}_r(y) \) does not depend on the choice of \( y \).

This integer \( \chi^{d_Y, s_Y}_r(y) \) is denoted by \( \chi^{d_Y, s_Y}_r \). We deduce from this Theorem 4.1 the following lower bounds in real enumerative geometry.

**Corollary 4.2** Under the assumptions of Theorem 4.1 denote by \( R_{d_Y}(y) \) the number of real irreducible rational curves passing through \( y \) in the class \( d_Y \) and by \( N_{d_Y} \) the associated Gromov-Witten invariant. Then, \( |\chi^{d_Y, s_Y}_r| \leq R_{d_Y}(y) \leq N_{d_Y} \). \( \square \)

### 4.1.2 Proof of Theorem 4.1

**Lemma 4.3** Let \( Y \) be the blown up of \( \mathbb{C}P^3 \) at a point and \( \text{Exc} \subset Y \) be the associated exceptional divisor. Then every morphism \( u : \mathbb{C}P^1 \to Y \) such that \( H^1(\mathbb{C}P^1; u^*TY) \neq 0 \) has an image contained in \( \text{Exc} \) which is a curve of degree greater than one.

**Proof:**

The manifold \( Y \) has a submersion \( p : Y \to \mathbb{C}P^2 = \text{Exc} \) whose fibers are rational curves. In fact, \( Y \) is isomorphic to the projectivization \( P(O_{\mathbb{C}P^2} \oplus O_{\mathbb{C}P^2}(1)) \). Denote by \( H = O_{\mathbb{C}P^2} \oplus O_{\mathbb{C}P^2}(1) \), \( L \subset p^*H \) the tautological subline bundle over \( Y \) and \( M = p^*H/L \). Denote by \( F \) the kernel of the morphism \( dp : TY \to T\mathbb{C}P^2 \), one has the isomorphism \( F \cong Hom(L, M) \cong L^* \otimes M \). Let \( u : \mathbb{C}P^1 \to Y \), from the short exact sequence

\[
0 \to O_{\mathbb{C}P^1}(u^*F) \to O_{\mathbb{C}P^1}(u^*TY) \to O_{\mathbb{C}P^1}(u^*T\mathbb{C}P^2) \to 0
\]

we deduce the long exact sequence

\[
\cdots \to H^1(\mathbb{C}P^1; u^*(L^* \otimes M)) \to H^1(\mathbb{C}P^1; u^*TY) \to H^1(\mathbb{C}P^1; (p \circ u)^*(T\mathbb{C}P^2)) \to \cdots
\]

Since \( \mathbb{C}P^2 \) is convex, \( H^1(\mathbb{C}P^1; (p \circ u)^*(T\mathbb{C}P^2)) = 0 \). Consider then the exact sequence

\[
0 \to u^*L \to (p \circ u)^*H \to u^*M \to 0
\]

Denote by \( b \) the degree of \( p \circ u : \mathbb{C}P^1 \to \mathbb{C}P^2 \), one has \((p \circ u)^*H \cong O_{\mathbb{C}P^1} \oplus O_{\mathbb{C}P^1}(b) \). We deduce the following alternative. Either \( u^*L \) is the unique subline bundle of \((p \circ u)^*H\) of degree \( b \), which implies \( \deg(u^*(L^* \otimes M)) = -b \) and \( H^1(\mathbb{C}P^1; u^*TY) \neq 0 \) as soon as \( b \geq 2 \). In this case, \( Im(u) \) is contained in \( \text{Exc} \). Or \( u^*L \) is not the unique subline bundle of \((p \circ u)^*H\) of degree \( b \), then \( \deg(u^*(L)) \leq 0 \) and \( \deg(u^*(M)) \geq b \). This implies that \( H^1(\mathbb{C}P^1; u^*(L^* \otimes M)) = 0 \) and thus \( H^1(\mathbb{C}P^1; u^*TY) = 0 \). \( \square \)
Proof of Theorem 4.1:
Let $\tau \in S_{k_d}$, having $\tau$ fixed points in $\{1, \ldots, k_{d'}\}$ and such that $\tau^2 = id$. Let $(\mathcal{M}_{0,k_d}(Y), c_{\mathcal{M},\tau})$ be the space of genus 0 stable maps of $Y$ having $k_{d'}$ marked points and realizing the homology class $d\tau$. This is a real algebraic subvariety of the variety $(\mathcal{M}_{0,k_d}(\mathbb{C}P^N), c_{\mathcal{M},\tau})$ associated to a real embedding $\pi : (Y, c_Y) \to (\mathbb{C}P^N, conj)$ such that $\pi_*d\tau = b$, see [2]. Denote by $\mathcal{M}_{0,k_d}(Y)^\#$ the complement in $\mathcal{M}_{0,k_d}(Y)$ of the locus of curves having a multiple component or a component included in $Exc$. This variety is smooth of dimension $c_1(Y)d_Y + k_{d'} = 3k_{d'}$, but not compact. However, the evaluation morphism $\mathcal{M}_{0,k_d}(Y)^\# \to Y^{k_{d'}}$ is proper over a generic path of $Y^{k_{d'}}$. Theorem 4.1 is then proven in the same way as Theorem 22. □

4.2 Relations between the coefficients of the polynomial $\chi^{d,s}(T)$

Denote once more by $(Y, c_Y)$ the real algebraic 3-manifold obtained after blowing up a real point $x_0$ of $(\mathbb{C}P^3, conj)$. Assume that the riemannian metric $g$ of $\mathbb{R}P^3$ fixed in [22] is flat in a neighborhood of $x_0$. Denote by $\overline{g}$ the associated metric of $\mathbb{R}P^3$ and by $\overline{R}_X$ the $SO_3(\mathbb{R})$- principal bundle of direct orthonormal frames of $\mathbb{R}P^3$. Let $\overline{P}_X \to \overline{R}_X$ be a $Spin_3$-principal bundle defining a spin structure $\overline{s}$ on $\mathbb{R}P^3$. Making a surgery in a neighborhood of $x_0$ which is small enough, the manifold $\mathbb{R}Y = \mathbb{R}P^{3+2}\#\overline{R}^3$ comes equipped with a riemannian metric $g\#\overline{g}$. Denote by $R_Y$ the associated $SO_3(\mathbb{R})$-principal bundle of direct orthonormal frames. The bundles $P_X$ and $\overline{P}_X$ glue together to form a $Spin_3$-principal bundle $P_Y$ over $R_Y$ which defines a spin structure on $\mathbb{R}Y$ denoted by $s\#\overline{s}$.

**Theorem 4.4** Let $(Y, c_Y)$ be the blown up of $(\mathbb{C}P^3, conj)$ at a real point $x_0$, $s$ be a spin structure on $\mathbb{R}P^3$ and $s\#\overline{s}$ be the associated spin structure on $\mathbb{R}Y$. Let $d \in \mathbb{N}^*$, $d_Y = d(f+l) - 2l \in H_2(Y; \mathbb{Z})$ and $k_d = 2d$. Then, for every integer $r$ between 2 and $k_d-2$, we have $\chi^{d,s} = \chi^{d,s} - 2\chi^{d_Y,s\#\overline{s}}$.

(The classes $f$ and $l$ in $H_2(Y; \mathbb{Z})$ have been defined in [1.1.1])

**Lemma 4.5** Let $u : \mathbb{C}P^1 \to \mathbb{C}P^3$ be a morphism passing through $x_0 \in \mathbb{C}P^3$, which is an immersion in the neighborhood of $u^{-1}(x_0)$. Denote by $N_u$ the normal bundle of $u$ in $\mathbb{C}P^3$ and by $z = u^{-1}(x_0) \subset \mathbb{C}P^1$. Let $Y$ be the blown up of $\mathbb{C}P^3$ at $x_0$, $\tilde{u} : \mathbb{C}P^1 \to Y$ be the strict transform of $u$ and $N_{\tilde{u}}$ be its normal bundle in $Y$. Then one has the isomorphism :

$$N_{\tilde{u}} \cong N_u \otimes \mathcal{O}_{\mathbb{C}P^1}(-z).$$

□

It follows in particular from this lemma that if $u$ is balanced, then so is $\tilde{u}$.

**Proof of Theorem 4.4**:
The begining of this proof is the same as the one of Theorem 3.2 of [15]. Let $x^+ = (x_1, \ldots, x_{k_d})$ be a generic real configuration of $k_d$ distinct points of $\mathbb{C}P^3 \setminus \{x_0\}$, $r+2$ of which are real. Let two such real points, say $x_{k_d-1}$ and $x_{k_d}$, converge to $x_0$ along a generic real tangency $\tau_0 \in P(T_{x_0}\mathbb{R}P^3)$. Denote by $z^\infty$ the configuration of points $(x_1, \ldots, x_{k_d-2}, x_0)$ in the limit. The rational curves in the set $\mathcal{R}_d(x^+)$ converge to immersed irreducible real rational curves passing through $z^\infty$ and either having the tangency $\tau_0$ at $x_0$, or having a real ordinary double point at $x_0$ which is the local intersection of two real branches. The latter are the
limit of exactly two curves of $\mathcal{R}_d(x^+)$, denote by $\text{Lim}^+(x_\infty)$ their set. Similarly, $x_\infty$ is the limit of a generic real configuration $x^-$ of $k_d$ distinct points of $\mathbb{CP}^3 \setminus \{x_0\}$, $r$ of which being real, when two complex conjugated points of $x^-$ converge to $x_0$ along a generic real tangency $\tau_0 \in P(T_{x_0}\mathbb{RP}^3)$. The rational curves in the set $\mathcal{R}_d(x^-)$ converge to immersed irreducible real rational curves passing through $x_\infty$ and either having the tangency $\tau_0$ at $x_0$, or having a real ordinary double point at $x_0$ which is the local intersection of two complex conjugated branches. The latter are the limit of exactly two curves of $\mathcal{R}_d(x^-)$, denote by $\text{Lim}^-(x_\infty)$ their set. It follows easily that

$$\chi_{n+2}^{d,g} - \chi_r^{d,g} = 2 \left( \sum_{A \in \text{Lim}^+(x_\infty)} sp(A) - \sum_{A \in \text{Lim}^-(x_\infty)} sp(A) \right).$$

For every curve $A \in \text{Lim}^+(x_\infty) = \text{Lim}^+(x_\infty) \cup \text{Lim}^-(x_\infty)$, denote by $A_Y$ its strict transform in $Y$. The curves $A_Y$, $A \in \text{Lim}^+(x_\infty)$, are exactly the elements of the set $\mathcal{R}_{d_Y}(y)$, for $y = (x_1, \ldots, x_{k_d-2}) \in Y^{k_d-2}$. When $A \in \text{Lim}^-(x_\infty)$, it follows from the construction of the spin structure $s \# \overline{s}$ that $sp(A_Y) = sp(A)$. We have thus to prove that when $A \in \text{Lim}^+(x_\infty)$, $sp(A_Y) = -sp(A)$. Let $(e_1(p), e_2(p), e_3(p))_{p \in \mathbb{RP}^3}$ be a loop in the bundle $R_Y$ of direct orthonormal frames of $\mathbb{RP}^3$ in the neighborhood of $x_\infty$ so that $sp(A_Y)$ is the obstruction to lift this loop as a loop in $P_Y$. Fix an orientation of $\mathbb{RP}^3$, which induces also an orientation of the normal bundle of $\mathbb{RP}^3$ in $\mathbb{RP}^3$, and let $\mathbb{RP}^3 \cap \mathbb{RP}^3 \text{Exc} = \{p_0, p_1\}$. We construct then the loop $(\tilde{e}_1(p), \tilde{e}_2(p), \tilde{e}_3(p))$ of $\mathbb{RP}^3$ as the concatenation of the four following paths. The path $(e_1(p), e_2(p), e_3(p))_{p \in [p_0, p_1]}$, then a path completely included in the fiber of $R_Y$ over $p_1$. This path is obtained from $(e_1(p_1), e_2(p_1), e_3(p_1))$ by having this frame turning of half a twist in the positive direction around the axis generated by $e_1(p_1)$. The end point of this path is thus the frame $(e_1(p_1), -e_2(p_1), -e_3(p_1))$. Then the path $(e_1(p), -e_2(p), -e_3(p))_{p \in [p_0, p_1]}$, finally, a path completely included in the fiber of $R_Y$ over $p_0$. This path is obtained from $(e_1(p_0), -e_2(p_0), -e_3(p_0))$ by having this frame turning of half a twist in the negative direction around the axis generated by $e_1(p_0)$. The end point of this path is thus the frame $(e_1(p_0), e_2(p_0), e_3(p_0))$, so that we have indeed constructed a loop in $R_Y$ which is homotopic to the initial loop $(e_1(p), e_2(p), e_3(p))_{p \in \mathbb{RP}^3}$. Remember that $\mathbb{RP}^3$ is obtained as the connected sum of $\mathbb{RP}^3$ and $\mathbb{RP}^3$ in the neighborhood of $x_0$. We may choose the radius of the ball used to perform the connected sum as small as we want, and have this radius converging to zero. In this process, the curve $\mathbb{RP}^3$ degenerates to the union of the curve $\mathbb{RP}^3 \subset \mathbb{RP}^3$ and two lines $\mathbb{RP}^3, \mathbb{RP}^3$ passing through $x_0$. The loop $(\tilde{e}_1(p), \tilde{e}_2(p), \tilde{e}_3(p))$ of $\mathbb{RP}^3$ degenerates to the union of a loop $(\tilde{e}_1, \tilde{e}_2, \tilde{e}_3)_{|\mathbb{RP}^3}$ of $\mathbb{RP}^3$ and two loops $(\tilde{e}_1, \tilde{e}_2, \tilde{e}_3)_{|\mathbb{RP}^3}$. By construction, the obstruction to lift $(\tilde{e}_1, \tilde{e}_2, \tilde{e}_3)_{|\mathbb{RP}^3}$ to $P_X$ is exactly $sp(A)$. Similarly, the homotopy class of the loop $(\tilde{e}_1, \tilde{e}_2, \tilde{e}_3)_{|\mathbb{RP}^3}$ differs from the one of $(\tilde{e}_1, \tilde{e}_2, \tilde{e}_3)_{|\mathbb{RP}^3}$ by a non-trivial loop in a fiber of $P_X$. We deduce that $sp(\mathbb{RP}^3) = -sp(\mathbb{RP}^3)$ independantly of the choice of a spin structure on $\mathbb{RP}^3$. It follows that $sp(A_Y) = sp(A)sp(\mathbb{RP}^3)sp(\mathbb{RP}^3) = -sp(A)sp(\mathbb{RP}^3)^2 = -sp(A)$. \[ \square \]
