Abstract

The 2-dimensional charge transport with parallel (in plane) magnetic field is considered from the physical and mathematical point of view. To this end, we start with the magnetic field parallel to the plane of charge transport, in sharp contrast to the configuration described by the theorems of Aharonov and Casher where the magnetic field is perpendicular. We explicitly show that the specific form of the arising equation enforce the respective field solution to fulfil the Majorana condition. Consequently, as soon any physical system is represented by this equation, the rise of fields with Majorana type behaviour is immediately explained and predicted. In addition, there exists a quantized particular phase that removes the action of the vector potential producing interesting effects. Such new effects are able to explain due the geometrical framework introduced, several phenomenological results recently obtained in the area of spintronics and quantum electronic devices. The quantum ring as spin filter is worked out in this framework and also the case of the quantum Hall effect.
I. INTRODUCTION

In 1937 Ettore Majorana propose a new representation to the celebrated Dirac equation, where the components of the spinor solution are related themselves by complex conjugation [11]. Due his personal problems, he could not have foreseen the whirlwind of activity that would follow: not only in particle physics but also in nanoscience and condensed matter physics (for a review about this issue in condensed matter see [14]). The recent storm of activity in condensed matter physics has focused on the ‘Majorana zero modes’ i.e. emergent Majorana-like states occurring at exactly zero energy that have a remarkable property of, if
they are considered as particles, being their own antiparticles (self-conjugated). Sometimes, this property is expressed as an equality between the particle’s creation and annihilation operators. As we will see below, there exists the general idea that any ordinary fermion can be though of as composed of two Majorana fermions: this is only a partial picture, the real fact is that there exists a particular representation were a fermion efectively can be represented as bilinear combination of two states of fractionary spin [8]. For example, the considered in condensed matter physics ”Majorana zero modes” are believed to exhibit the so called non-Abelian exchange statistics [4, 5] which endows them with a technological potential as building blocks of future quantum memory immune against many sources of decoherence. Recent advances in our understanding of solids with strong spin-orbit coupling, combined with the progress in nanofabrication, put the physical realization of the Majorana states to be considered as possible. In fact signatures consistent with their existence in quantum wires coupled to conventional superconductors and other type of devices have been reported by several groups [12].

By the other hand and with other motivations, Aharonov and Casher [1] proved two theorems for the case of a 2-D magnetic field. The first theorem states that an electron moving in a plane under the influence of a perpendicular inhomogeneous magnetic field has \( N \) ground-energy states, where \( N \) is the integral part of the total flux in units of the flux quantum \( \Phi_0 = 2\pi/e \equiv hc/e \) (m=1). The corresponding Dirac equation for the Aharonov-Casher-Theorem (ACT) configuration is [1]

\[
[\sigma_x (\partial_x - ieA_x) + \sigma_y (\partial_y - ieA_y)] \varphi = 0
\]  

(A)

We introduce the transformation

\[
\psi = e^{e\phi\sigma_z} \varphi
\]  

(B)

this transformation (phase) permits us to eliminate the magnetic field explicitly from the Dirac equation where \( \phi \) satisfies the relations

\[
\partial_x \phi = A_y, \quad \partial_y \phi = -A_x
\]

and \( \varphi \) is eigenfunction of \( \sigma_z \) (\( \sigma_z \varphi_s = s \varphi_s \)). Having into account that \( B(x,y) = \partial_x A_y - \partial_y A_x \) we arrive to

\[
B(x,y) = \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \phi
\]
It is easy to see that (asymptotically) for \( r \to \infty \) we have

\[
\phi(x, y) = \frac{\Phi}{2\pi} \ln \left( \frac{r}{r_0} \right)
\]

where

\[
\Phi = \int B(x, y) \, dx \, dy
\]

is the total magnetic flux through the \((x, y)\)-plane, \( r_0 \) is some real constant. Consequently we immediately obtain

\[
\varphi_s = \left( \frac{r_0}{r} \right)^{\frac{\Phi_s}{\Phi_0}} \psi_s(w)
\]

where \( w = x + isy \) and \( \psi_s(w) \) is an entire function of \( w \) because after the elimination of the magnetic field from the equation (A) it takes the simplest form

\[
(\partial_x + is\partial_y) \psi_s(w) = 0
\]

In order that \( \varphi_s \) to be square integrable function we should consider \( \Phi_s > 0 \) and \( \psi_s \) has to be a polynomial whose degree is not greater than \( N - 1 \), where \( N = \{\Phi/\Phi_0\} \), obtaining \( N \) independent solutions for \( \psi_s : 1, w, w^2, \ldots, w^{N-1}. \) Through this paper the same procedure as for the ACT configuration will be performed but in the case of ”in plane” (parallel) magnetic field [2,3,4,5].

The plan of this paper is as follows. Section II we obtain the conditions whether the magnetic field parallel to the charge transport can be ”removed” as in the ACT. In Section III we obtain the conditions fulfilled by the solution: types of spinors and flux quantization. Section III, the origin and conditions whether the quantum Hall effect appears from the ”in plane” magnetic field are explicitly shown. Magnetic field parallel and the quantum ring as an application (e.g. spin-filter) is the focus of Section V. The remanent Section are devoted to discuss, give some concluding remarks and perspectives.

II. MAGNETIC FIELD ”IN PLANE”

Now the magnetic field \( B \), in contrast to the ACT configuration described before, is parallel to the plane defined by \( x, y \) axis (usually denominated: "\( B \) in plane") where the particle lives. Explicitly the Dirac equation with the magnetic field parallel takes the following form:

\[
[\sigma_B \partial_B + \sigma_\perp (\partial_\perp - ie A_\perp) - ie \sigma_z A_z] \varphi = 0
\]

(1)
here, the subscripts \( B, \perp \) and \( z \) denote the direction of the \( B \) field in the plane, the direction of the component of the potential vector in the plane (obviously, perpendicular to the \( B \) direction) and the direction of component of the potential vector coincident with the \( z \) axis, respectively.

Defining \( \omega \) the angle of the magnetic field with respect the \( x \) axis in the plane \( x-y \), the transformation (B) takes in this case, the following general form.

\[
\psi = e^{i(\alpha \sigma_x + \beta \sigma_y)} \varphi = e^{i \phi \sigma_B \varphi} \quad (2)
\]

with

\[
\alpha = \lambda \cos \omega, \quad \beta = \lambda \sin \omega \quad (3)
\]

\[
|\phi|^2 = \lambda^2 (\cos^2 \omega + \sin^2 \omega) = \lambda^2 \Rightarrow |\phi| = \pm |\lambda| \quad (4)
\]

E.g. the projection of the field \( \phi \). Equation (1) explicitly written having account (2), is

\[
[\sigma_x \partial_x + \sigma_y \partial_y - ieA_\perp (\sigma_x \sin^2 \omega + \sigma_y \cos^2 \omega) - ie\sigma_z \sigma_\perp] \varphi = 0 \quad (5)
\]

It is easily seen that, when \( \omega = 0 \) \( B \) coincides with \( x-axis \) and when \( \omega = \pi/2 \), \( B \) coincides with the \( y-axis \). Also the Lie algebraic relation holds

\[
\sigma_B \sigma_\perp = (\cos \omega \sigma_x + \sin \omega \sigma_y) (-\sin \omega \sigma_x + \cos \omega \sigma_y) = i\sigma_z \quad (6)
\]

as expected.

Operating analogically as in the ACT configuration but having into account the new transformation and the physical situation, we obtain the conditions where the magnetic field can be eliminated. Precisely using expression (2) in (1) we obtain explicitly the following non trivial conditions in order to remove the magnetic field

\[
-\partial_\perp \phi = iA_z \quad \partial_B \phi = -A_\perp \sigma_\perp \quad (7)
\]

The first equation is precisely as in the ACT case but for the second one the interpretation is more involved and suggest, in principle, a complex structure for the field \( \phi \) in a doublet form. Knowing that the doublet can be written as

\[
\phi \equiv \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} \quad (8)
\]
the previous expressions take the following explicit form

\[- \partial \phi_1 = - \partial \phi_2 = iA_z \text{ and } \partial B \phi_1 = - \partial B \phi_2 = iA_\perp \quad (9)\]

Notice that above condition, in general, suggest the introduction of 2 real functions \(u\) and \(v\) as

\[
\phi \equiv \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} = \begin{pmatrix} \phi_1 \\ \phi_1^* \end{pmatrix} = \begin{pmatrix} u(x_\perp) + iv(x_B) \\ (u(x_\perp) + iv(x_B))^* \end{pmatrix}
\]

in such a manner that the the conditions to remove the magnetic field are automatically fulfiled as

\[- \partial \phi = iA_z \text{ and } \partial B \phi = A_\perp \quad (10)\]

Equation (9b) is nothing more that the Majorana condition over \(\phi\) that appear as consequence of the existence of a parallel magnetic field.

**A. Structure of the magnetic field: conditions over \(A\) and \(\phi\)**

The magnetic field that can be effectively generated \((B = \nabla \wedge A)\) from the vector potential components of our problem, namely \(A_z\) and \(A_\perp\).

The ”in plane” magnetic field is consequently

\[B_B = (\partial_\perp A_z - \partial_z A_\perp) \quad (11)\]

where the simplest possibility was took: \(A \neq A(x_B)\) e.g. the vector potential does not depends on the direction of the magnetic field, only on the plane defined by \(x_\perp\) and \(x_z\)(consistly as for the magnetic field in the ACT configuration). From (10) follows

\[B = i\partial_\perp^2 \phi = \frac{\Phi}{x_\perp} \quad (12)\]

where the total transversal flux to the plane per unit of longitude was used. Then, \(\phi\) is immediately obtained

\[\phi \cdot \sigma_B = -i (\Phi \sigma_B) x_\perp \left[ \ln \left| \frac{x_\perp}{l_0} \right| - \frac{C - x_\perp}{x_\perp} \right] \quad (13)\]

Putting the arbitrary constant \(C = 0\) for simplicity, the behaviour of the exponential function in (2) for \(\varphi\) determined

\[e^{-ie\Phi \cdot \sigma_B} = \left| \frac{l_0}{x_\perp} \right| \frac{\Phi^{x_\perp}}{\sigma_B^{x_\perp}} e^{-\frac{e \Phi \sigma_B}{x_\perp}} \quad (14)\]
with $l_0$ some real constant with units of length (its physical meaning will be analyzed later). As in the ACT case, the following condition must be fulfilled in order that $\varphi$ be normalizable and square integrable

$$\Phi s_B \geq 0$$  \hspace{1cm} (15)

($s_B$ is the spin in the B direction) due

$$\varphi = e^{-ie\phi \cdot \sigma_B} \psi (s, w)$$  \hspace{1cm} (16)

In the above expression, the function $\psi$ depends on the spin and some complex variable $w$ to determine from the simple Dirac-Weyl equation obtained after the procedure of explicit elimination of the magnetic field.

**B. Majorana, Dirac-Weyl states and discrete coordinates: conditions over $\psi(s, z)$**

the simple Dirac-Weyl equation obtained after ”removing the magnetic field” is

$$\left( e^{-ie\phi \cdot \sigma_B} \sigma_B \partial_B + e^{ie\phi \cdot \sigma_B} \sigma_\perp \partial_\perp \right) \psi (s, z) = 0$$  \hspace{1cm} (17)

to solve the equation a quantization should be imposed on the flow (strictly on the product $\phi \cdot \sigma_B$). This fact will induce an automatic discretization over the in plane transverse coordinate $x_\perp$.

$$\phi \cdot \sigma_B = n\pi, \hspace{0.5cm} n = 0, 1, 2, \ldots$$  \hspace{1cm} (18)

If above condition holds, we obtain

$$\left( \sigma_B \partial_B + \sigma_\perp \partial_\perp \right) \psi (s, z) = 0$$  \hspace{1cm} (19)

This expression is very important: this is a simple 2 dimensional Dirac equation *without* $A_\mu$. The particular phase introduced as ansatz plus a quantization condition indicate that the effect of the magnetic field (due the potential vector) can be removed.

**C. Analysis of the solution**

Looking the specific form of the above equations, there are two possibilities over the spin behaviour of $\psi$

i) $\sigma_B \psi (s, z) = s\psi (s, z)$ (eigenspinor of $\sigma_B$)
this case is compatible with the assumption that the state is eigenvector of the spin in the magnetic field direction. The Dirac equation is reduced to

\[
\left( \partial_B + \frac{iC}{s} \partial_\perp \right) \psi (s, z) = 0
\]

with \( C \) the charge conjugation operator. Then, \( \psi (s, z) \), and for instance \( \varphi (s, z) \) must fulfill the Majorana condition:

\[
C \varphi (s, z) = \pm c \varphi (s, z)
\]

Similarly as in the AC case, \( \psi (s, z) \) is an entire function of \( z = x_B + \frac{is}{s} x_\perp \) but the states solution is of Majorana type.

ii) \( \sigma_z \psi (s, z) = s \psi (s, z) \) (eigenspinor of \( \sigma_Z \)) in this case the spin remains as in the ACT situation (e.g. in the \( z \) direction). Now the Dirac equation is reduced to

\[
(\partial_B + is \partial_\perp) \psi (s, z) = 0
\]

Similarly as in the AC case, \( \psi (s, z) \) is an entire function of \( z = x_B + isx_\perp \), and the state solution is Dirac-Weyl.

The specific form of the equation (20) shows that the result is not casuality: the states are Majorana. The inclusion of the charge conjugation operator \( C \) due the symmetry of the physical scenario, enforces obviously, the Majorana condition over the states solution.

III. QUANTUM HALL EFFECT AND THE "IN PLANE" MAGNETIC FIELD

Is not difficult to see that, if the plane where the charges are moving is finite an "in plane" current transversal to the magnetic field \( B \) must appear (e.g in the \( x_\perp \) direction). This current will be quantized due the condition (18). This condition explicitly can be written

\[
\phi \cdot \sigma_B = (\Phi \sigma_z) \vec{x}_\perp \left[ \ln \left| \frac{x_\perp}{l_0} \right| - 1 \right] = n\pi, \quad n = 0, 1, 2, \ldots
\]

where \( \vec{x}_\perp = \sigma_\perp x_\perp \) is a new matrix valuated coordinate that its meaning will be analyzed later.

The explicit formula for the Hall current coming from the expression for the surface current

\[
n \times B = K_{\text{surface}}
\]
(n: unitary vector normal to the interface surface) this current is obviously perpendicular to the "in plane" magnetic field (e.g. $x_\perp$ direction). Due the quantization condition, the "emergent" Hall current also is quantized leading the QHE

$$\frac{\Phi \nu}{x_\perp} = \frac{2\pi N \hbar v}{e x_\perp} x_\perp = K_{\text{surface}}$$

(25)

where is the versor in the $x_\perp$ direction.

A. Generalized momentum operators and Majorana conditions

The interpretation of the non standard Dirac equation

$$[\sigma_B \partial_B + \sigma_\perp (\partial_\perp - i e A_\perp) - i e \sigma_z A_z] \varphi = 0$$

(26)

can be elucidated rewritten it as

$$\left[ \sigma_B (\partial_B - i e \sigma_B \sigma_z A_z) + \sigma_\perp (\partial_\perp - i e A_\perp) \right] \varphi = 0 \Rightarrow$$

$$\left[ \sigma_B \bar{\Pi}_B + \sigma_\perp \Pi_\perp \right] \varphi = 0$$

(27)

then, the question that immediately appears is: who is the operator $\bar{\Pi}_B$? The answer is obvious, using the algebra (6)$\sigma_B \sigma_\perp = i \sigma_\perp$ and the definition of the charge conjugation operator as function of the sigma matrices, is easy to see that

$$(\partial_B - i e \sigma_B \sigma_z A_z) = (\partial_B + i e C A_z)$$

(28)

As in ordinary non abelian gauge theories, the operator $\bar{\Pi}_B$ seems as equipped with a non abelian vector potential $\bar{A}_B \equiv - C A_z$. This conceptual interpretation will be utilized in the next section for the analisis of the quantum ring.

IV. MAGNETIC FIELD PARALLEL AND THE QUANTUM RING

Was recently pointed out[6], that the Rashba and Dresselhaus spin-orbit interactions in two dimensions can be regarded as a non-Abelian gauge field reminiscent of the standard Yang-Mills in QFT [13]. The explanation given in such references is that the physical field
generated by the gauge field brings to the electron wave function a spin-dependent phase. This phase generally is called the Aharonov-Casher phase. In ref. [6] the authors showed that applying on an AB ring this non-Abelian field together with the usual vector potential, is certainly possible make the interference condition completely destructive for one component of the spin while completely constructive for the other component of the spin over the entire energy range. This enables us to construct a perfect spin filter. However in [6] the magnetic field was perpendicular to the plane of the ring. Now we will proceed analogously but considering the in plane magnetic field to see the physical consequences over the physical states and over the spin control. In order to perform the analysis and to compare with the case described in [6], the same method and definitions will be used remitting to the reader to ref. [6] for more details.

The general Dirac equation whith the magnetic field parallel ("in plane") in cylindrical coordinates takes the form

\[
\begin{align*}
\left[ \sigma_\rho \partial_\rho + \frac{1}{\rho} \sigma_\varphi \partial_\varphi - ie(-\sigma_\rho A_\rho \sin(\omega - \varphi) + \sigma_\varphi A_\varphi \cos(\omega - \varphi)) - ie\sigma_2 A_z \right] \hat{\varphi} &= 0 \\
\left[ \sigma_\rho \partial_\rho + \frac{1}{\rho} \sigma_\varphi \left( \partial_\varphi - ie\sigma_2 \frac{\tilde{A}_z}{2i A_z} \right) - ie(-\sigma_\rho A_\rho \sin(\omega - \varphi) + \sigma_\varphi A_\varphi \cos(\omega - \varphi)) \right] \hat{\varphi} &= 0
\end{align*}
\]  

(29)

(30)

where in the last equation the properties of the algebra described in the previous paragraph have been used in order to introduce the "non abelian" potential. Notice that in our case is not only a trick in sharp contras with other references in the literature. The explicit form of the Pauli matrices in the configuration that we are interested in are

\[
\begin{align*}
\sigma_\rho &= \sigma_x \cos \varphi + \sigma_y \sin \varphi \\
\sigma_\varphi &= \sigma_y \cos \varphi - \sigma_x \sin \varphi \\
\sigma_B &= \sigma_\rho \cos(\omega - \varphi) + \sigma_\varphi \sin(\omega - \varphi) \\
\sigma_\perp &= \sigma_\varphi \cos(\omega - \varphi) - \sigma_\rho \sin(\omega - \varphi)
\end{align*}
\]

(31)

(32)

(33)

(34)

However, \( \varphi \) is the angular cylindrical coordinate, \( \omega \) is the angle of the magnetic field parallel to the plane measured from the axis \( x \) (e.g. \( \varphi = 0 \)) and the state is denoted as \( \hat{\varphi} \).
For the ring configuration, and having account the condition that the potential doesn’t depend on the direction of the magnetic field, the Dirac equation takes this non abelian form

\[
\left[ \frac{1}{\rho} \sigma_\varphi \left( \partial_\varphi - ie\sigma_\rho \widetilde{A}_z \right) \right] \widehat{\varphi} = 0
\]

then, the corresponding second order equation suggests the Hamiltonian for the magnetic field in plane as

\[
\mathcal{H}_{\text{ring}} = \frac{1}{\rho^2} \left( \partial_\varphi - ie\sigma_\rho \widetilde{A}_z \right)^2
\]

Notice the non-abelian character of the above equation, that was described in the previous paragraph.

A. Screening of Rashba term and ”in plane’ magnetic field

When the Rashba spin-orbit interaction is introduced, the following Hamiltonian is obtained

\[
\mathcal{H}_{\text{ring}}\big|_{B_{\text{plane}}} = \frac{\hbar^2}{2m^*R^2} \left( -i\partial_\varphi - \sigma_\rho \left( \right) \right)^2
\]

\[
\mathcal{H}_{\text{ring}}\big|_{B_z} = \frac{\hbar^2}{2m^*R^2} \left( -i\partial_\varphi - \frac{\phi_B}{c \pi R^2 B_z} - \left( \sigma_\rho \frac{\theta R}{2} \right)^2
\]

where \( \theta \equiv \frac{2m^*\alpha}{\hbar} \) plays the role of coupling constant of the Rashba term (the same units as in reference [6]). The main point is that the vector potential corresponding to the” in plane” magnetic field (perpendicular to the plane of the ring) is at the same non-abelian level that the Rashba term.

In the case treated by the authors in [6], the magnetic field is perpendicular having the Hamiltonian for the ring the following fashion

\[
\mathcal{H}_{\text{ring}}\big|_{B_z} = \frac{\hbar^2}{2m^*R^2} \left( -i\partial_\varphi - \frac{\phi_B}{c \pi R^2 B_z} - \left( \sigma_\rho \frac{\theta R}{2} \right)^2
\]

where is easily seen that \( \phi_B \) is not at the same ”non abelian” level of the Rashba term. Consequently, is this the explanation of the screening of the Rashba interaction by the ”in plane” magnetic field.
B. Physical consequences and effects

We know from Section II that we can select solutions that are eigenfunctions of $\sigma_z$. Besides this issue, the potential vector $A_z$ must come perpendicularly to the ring plane ($\hat{z}$ direction) in concordance with the ACT situation. Notice that, in sharp contrast with previous references, the effective Hamiltonian arises from the true Dirac equation with minimal coupling. As we can assume in general that we know the magnetic field ($B_{pl}$) in the plane:

$$e\tilde{A}_z \equiv 2ieA_z = 2ieB_{pl}R/h,$$

then

$$\mathcal{H}_{\text{ring}}|_{B_{\text{plane}}} = \frac{\hbar^2}{2m^*R^2} \left[ -i\partial_{\phi} - \sigma_{\rho} \left( \frac{(\theta - 4eB_{pl}) R}{2} \right) \right]^2$$

the interplay between the magnetic field parallel to the plane of the ring and the Rashba interaction is clearly seen.

Assuming free interaction into the 2 leads, in response to

$$\mathcal{H}_{\text{lead}} = -\frac{\hbar^2}{2m^*} \partial_x^2$$

we obtain (same units and notation that in ref.[6]) for the ring Hamiltonian the wave functions

$$\Psi_{\pm} = e^{i(\pm k_{\phi} \pm \phi_T)_{\rho}} e^{-i\beta_{\phi}^2/2} \chi_{\pm}$$

($\chi_{\pm}$ eigenfunctions of $\sigma_z$) with the eigenvalues

$$E = \frac{\hbar^2 k_{\phi}^2}{2m^*\rho^2}$$

where now the total phase is

$$\phi_T = \sqrt{1 + (\theta - 4eB_{pl})^2 \rho^2 - 1}$$

and

$$\beta = \arctan \xi$$

with $$(\theta - 4eB_{pl}) \equiv \xi$$

Notice the important fact that the total phase $\phi_T$ is identically zero if the following condition holds

$$\theta = 4eB_{pl}$$
As in [6] the first sign of $\Psi_{\pm\pm}$ denotes the sign of the momentum, and the second one of the spin. In the phase corresponding to Rashba interaction, an small radius $\rho$ of the ring was considered. Following similar task that in [6] in order to realize a perfect spin filter, the wave function (41) at $\varphi = 2\pi$ is

$$\Psi_{\pm\pm}(2\pi, k_\varphi) = e^{\pm 2\pi i k_\varphi} U_{\text{phase}} \chi_{\pm}$$

realizing the spin filter by adjusting parameters:

$$2\pi \phi_T = (2n + 1)\pi$$

At this point, two important cases must be considered:

1. **Case a)**

   Considering (43) and small radius $\rho$, the above condition is translated to

   $$\xi \rho = \sqrt{n + 3/2}, \quad n \in \mathbb{Z}$$

   $$= \sqrt{3/2}, \sqrt{5/2}, \sqrt{7/2}, \ldots$$

2. **Case b)**

   Case (a) must be complemented with a condition that only appears as an effect of the existence of the magnetic field in plane that is

   $$\xi = 0 \rightarrow \theta = 4eB_{pl}$$

   Both conditions, realize the perfect spin filter being the second condition possible **only** in the case when the magnetic field is "in plane", and it importance will be more evident in the coefficient transmission description, as follows.

   The eigenvectors of the phase factor $U_{\text{phase}} = e^{\pm 2\pi i \phi_T} e^{-i\beta \sigma_y/2}$ can be exactly computed,

   $${\tilde{\chi}}_+ = \begin{pmatrix} \frac{\sqrt{\xi^2 + 1 + 1}}{2} \\ \xi/2 \end{pmatrix}$$

   $${\tilde{\chi}}_- = \begin{pmatrix} \xi/2 \\ -\frac{\sqrt{\xi^2 + 1 + 1}}{2} \end{pmatrix}$$
Notice that when the critical value $\theta = 4eB_{pl}$ holds, then $\xi = 0$ consequently the eigenvectors $\tilde{\chi}_\pm$ goes automatically to $\chi_\pm$ (eigenvectors of $\sigma_z$) as expected in sharp contrast with similar results in [6] that they correctness is doubtful. Although there are several effective manners to compute the transmission coefficients, we following ref. [6] in order to compare the results with other works involving the similar devices. We first assume the amplitudes of the left-going and right-going wave functions separately for the left lead, the portion $0 < \varphi < \pi$ of the ring, the portion $\pi < \varphi < 2\pi$ of the ring, and the right lead. This amounts to sixteen amplitudes in total when we take the spin degree of freedom into account. The continuation of the wave function at $\varphi = 0$ and $\varphi = \pi$ give eight conditions and the conservation of the generalized momentum at $\varphi = 0$ and $\varphi = \pi$ give four conditions. Then, four degrees of freedom finally remain. The S-matrix of the quantum ring is obtained by expressing the four amplitudes of the out-going waves (the left-going wave on the left lead and the right-going wave on the right lead with spin up and down) in terms of the four amplitudes of the incoming waves (the right-going wave on the left lead and the left-going wave on the right lead with spin up and down). The off-diagonal $2 \times 2$ block of the $4 \times 4$ S–matrix give the transmission coefficients. In our case, the transmission coefficients are proportional to

$$T_{\parallel}, T_{\parallel} \propto |1 + e^{2\pi i \varphi_e}|^2$$

$$T_{\parallel}^\perp, T_{\parallel}^\perp \propto |1 + e^{-2\pi i \varphi_e}|^2$$

where $\parallel$ and $\perp$ denote respectively the spin up (49) and spin down (50) diagonalizing the phase factor $U_{phase} = e^{\pm 2\pi i \varphi_e}e^{-i\beta \sigma_y / 2}$.

Summarizing: in the case a) evidently $T_{\parallel}, T_{\parallel}^\perp, T_{\parallel}^\perp, T_{\parallel} = 0$, and in the case b) the transmission coefficients are constant, realizing together the perfect spin filter [6,7].

V. CONCLUDING REMARKS AND OUTLOOK

In this letter the 2-dimensional charge transport with parallel (in plane) magnetic field was considered. The starting point was reminiscent as the described in the Aharonov and Casher theorems but with the magnetic field parallel to the plane of charge transport. In this first paper, several important results were found of which we can conclude enumerating the following issues:

i) the specific form of the arising equation enforce the respective field solution to fulfil
the Majorana condition;

ii) when any physical system is represented by this equation the rise of fields with Majorana type behaviour is immediately explained and predicted;

iii) there exists a quantized particular phase that removes the action of the vector potential and this produces interesting effects being the Quantum Hall Effect (QHE) one of them that is straightforwardly explained;

iv) the interpretation of Dirac equation with a non abelian electromagnetic field appears in consequence of the conditions imposed on the fields, not as an added ”by hand”;

Also the quantum ring was treated as example where these new effects must appear.

As was mentioned in some references, the term non-abelian was introduced ”by hand” in order to reproduce the effects of the interaction of type RD. In our case, the ”non-abelian” term appears due to the presence of the field parallel to the transport plane of the charges. Therefore, and as we saw in the problem of the ring in Section 4, there is competition or screening between the effects produced by the interaction RD and from the parallel magnetic field. This competition brings two important consequences, namely:

1) new spin filter effects (different in essence to [6]) , as we have analyzed from Section 4

2) measurable effects of screening that could give a clear explanation of the new effects observed in planar nanostructures described in references [9].

In the second part of this letter [10], the relationship between the hidden symmetries of the particular physical systems described by this equation and the(e.g. nanostructures, composite particle states etc.)will be discussed and elucidated with a clear explanation about Majorana, zero modes and supersymmetry.

VI. ACKNOWLEDGEMENTS

We are very grateful to the CONICET (Argentina) and the Bogoliubov Laboratory of Theoretical Physics (BLTP-JINR) for their hospitality and finnancial support and to the professor R.G. Nazmitdinov for introduce me in the subject of the transport of charged particles in nanostructures.
