1 Introduction

Recently a series of papers has been published concerning so-called strongly correlating liquids and their physical properties [1–6]. Liquids that exhibit these strong correlations have simpler thermodynamic, structural, and dynamical properties than liquids in general. A strongly correlating liquid is identified by looking at the correlations of the equilibrium fluctuations of the potential energy $U(r_1,\ldots,r_N)$ and virial $W(r_1,\ldots,r_N) \equiv -1/3 \sum_i r_i \cdot \nabla_r U(r_1,\ldots,r_N)$ [7] at constant volume:

$$R = \frac{\langle DW \Delta U \rangle}{\sqrt{\langle (\Delta W)^2 \rangle \langle (\Delta U)^2 \rangle}}. \quad (1)$$

Here brackets denote averages in the NVT ensemble (fixed particle number, volume, and temperature), $\Delta$ denotes the difference from the average. The virial $W$ gives the configurational part of the pressure [7],

$$pV = Nk_BT\sum_i p_i + W(r_1,\ldots,r_N). \quad (2)$$

Strongly correlating liquids are defined [1] as liquids that have $R \geq 0.9$.

The origin of strong $WU$ correlations was investigated in detail in references [3,4] for systems interacting via the Lennard-Jones (LJ) potential:

$$v(r) = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6. \quad (3)$$

The fluctuations of $W$ and $U$ are dominated by fluctuations of pair distances within the first neighbor shell, where the LJ potential is well approximated by an extended inverse power law (IPL) plus a linear term [3]:

$$v_{\epsilon I P L}(r) = Ar^{-n} + B + Cr. \quad (4)$$

The IPL term gives perfect $WU$ correlations, whereas the linear term contributes little to the fluctuations at constant volume: when one pair distance increases, others decrease, keeping the contributions from the linear term almost constant (this cancellation is exact in one dimension). The consequence is that LJ systems inherit some of the scaling properties of the IPL potential – they have a “hidden scale invariance” [4,8]. Prominent among the properties of strongly correlating liquids is that they have “isomorphs”, i.e., curves in the phase diagram along which structure, dynamics, and some thermodynamical properties are invariant in appropriate units [5,6]. The physics of strongly correlating liquids was briefly reviewed recently in reference [9].

Since the LJ system consists of two IPL terms, it is perhaps tempting to assume that a repulsive (inverse)
power law is necessary for the hidden scale invariance described above. In the present paper we use the modified Buckingham (exp-six) pair potential to show that this is not the case. The Buckingham potential was first derived by Slater from first-principle calculations of the force between helium atoms \[10\]. Buckingham later used this form of the potential to calculate the equation of state for different noble gases \[11\]. The Buckingham potential has an exponential repulsive term, while the attractive part is given by a power law \[12,13\]:

\[
v(r) = \epsilon \left( \frac{6}{\alpha - 6} \exp \left[ \alpha \left( 1 - \frac{r}{r_m} \right) \right] - \frac{\alpha}{\alpha - 6} \left( \frac{r_m}{r} \right)^\alpha \right).
\]

Here \( \epsilon \) is the depth of the potential well and \( r_m \) specifies the position of the potential minimum. The parameter \( \alpha \) determines the shape of the potential well. The Buckingham potential is better able to reproduce experimental data of inert gases than the LJ potential \[14–16\], but is also computationally more expensive (unless look-up tables are utilized \[7\]).

All simulation data in this paper were obtained from molecular dynamics in the NVT ensemble. The samples contained 1000 particles. The simulations were set up by instant cooling from a high temperature state point followed by an equilibration period, to ensure the simulations were independent from each other. The simulations were performed with the RUMD molecular dynamics package \[17\], which is optimized for doing computations on state-of-the-art GPU hardware.

### 2 Correlations in single-component Buckingham liquids

To compare the simulations with experiments \[18\], argon parameters from reference \[14\] were used; \( \alpha = 14.0, r_m = 0.3866 \text{ nm}, \epsilon/k_B = 123.2 \text{ K} \). As can be seen in Figure 1a, the single-component Buckingham (SCB) liquid is strongly correlating \( (R \geq 0.9) \) in parts of the phase diagram, particularly at high densities and/or temperatures. The correlation coefficients (Eq. (1)) of the Buckingham systems are very similar to those of argon and the LJ system (dotted line in Fig. 1). This is a first indication that the actual functional form of the repulsive part of the potential does not have to be an inverse power law in order for a system to exhibit strong \( WU \) correlations.

Another interesting property of the fluctuations is the quantity \( \gamma \) defined \[4,5\] as

\[
\gamma = \frac{\langle \Delta W \Delta U \rangle}{\langle (\Delta U)^2 \rangle}.
\]

When a system is strongly correlating \( (R \text{ is close to one}) \), \( \Delta W \approx \gamma \Delta U \). For IPL potentials \( \gamma \) is constant and equal to \( n/3 \) and \( R = 1 \). For non-IPL potentials, however, \( R < 1 \) and \( \gamma \) may change with temperature and density as seen in Figure 1b \[1,19\]. Especially for \( R < 0.9 \), we find \( \gamma \) changing rapidly. The curves are similar for the 20.0 mol/L SCB and SCLJ systems, except for a vertical offset.

Fluctuations in \( U \) and \( W \) are of course only directly accessible in simulations. For experimental systems one must revert to the use of thermodynamic quantities that reflect the fluctuations in \( U \) and \( W \). For instance, the configurational part of the pressure coefficient \( \beta_u^V = \frac{\partial(W/V)}{\partial T} V \) and the configurational part of the isochoric specific heat per unit volume \( c_V^T = \frac{\partial(U/V)}{\partial T} V \) can be used to to calculate \( \gamma \) for argon as follows \[1,3,5\]:

\[
\gamma = \frac{\beta_u^V}{c_V^T}.
\]

The values of \( \gamma \) for argon obtained in this way are plotted in Figure 1b, and the agreement with the Buckingham systems is good. This confirms that the Buckingham potential produces more accurate predictions of experimental argon data than the LJ potential.

Interestingly, low density argon has a higher correlation coefficient than high density argon. This is the opposite of what is found for the Buckingham and the LJ potentials. Furthermore, the buckingham data are in better agreement with the argon data at low density than at high density. At the present we do not have any explanation for these observations.
3 Isomorphs in binary Buckingham mixtures

Strongly correlating liquids are predicted to have isomorphs, which are curves in the phase diagram along which structure, dynamics, and some thermodynamical properties are invariant in appropriate reduced units [5,6]. Introducing reduced coordinates as $\tilde{r}_i = \rho^{1/3}r_i$, two state points (1) and (2) are defined to be isomorphic if pairs of microscopic configurations with same reduced coordinates $(\tilde{r}_i^{(1)} = \tilde{r}_i^{(2)})$ have proportional configurational Boltzmann weights:

$$e^{-U(r_1^{(1)}, ..., r_n^{(1)})/k_B T_1} = C_{12} e^{-U(r_1^{(2)}, ..., r_n^{(2)})/k_B T_2},$$

(8)

Here the constant $C_{12}$ depends only on the two state points and equation (8) is required to hold to a good approximation for all physically relevant configurations [6].

An isomorph is a curve in the phase diagram for which all points are isomorphic (an isomorph is a mathematical equivalence class of isomorphic state points). The isomorphic invariance of structure, dynamics, and some thermodynamical properties – all in reduced units – can be derived directly from equation (8) [5]. Only IPL liquids have exact isomorphs, but it has been shown that all strongly correlating liquids have isomorphs to a good approximation (Appendix A of Ref. [5]).

Among the thermodynamical properties that are isomorphic invariant is the excess entropy, $S_{ex} ≡ S - S_{ideal}$, where $S_{ideal}$ is the entropy of an ideal gas at the same temperature and density. In the following, isomorphic state points were generated by utilizing that the quantity $\gamma$ in equation (6) can be used to change density and temperature while keeping the excess entropy constant [5,6]:

$$\gamma = \left( \frac{\partial \ln T}{\partial \ln \rho} \right)_{S_{ex}}.$$

(9)

By choosing the density of a new isomorphic state point close to the density of the previous isomorphic state point, the temperature of the new state point can be calculated from the fluctuations by combining equations (6) and (9) [5]. In this way a set of isomorphic points can be obtained from one initial state point.

The predicted isomorphic invariance of the dynamics is most striking in viscous liquids, where the dynamics in general depend strongly on temperature and density. To demonstrate that systems interacting via the Buckingham potential have isomorphs, we study what we term a Kob-Andersen binary Buckingham (KABB) mixture with potential parameters being the same as for the original Kob-Andersen binary LJ (KABLJ) mixture [21]: $\epsilon_{AA} = 1.0$, $r_{m,AA} = 1.5$, $\epsilon_{AB} = 0.8\sqrt{2}$, $r_{m,AB} = 0.88\sqrt{2}$, $\epsilon_{BB} = 0.5$, $r_{m,BB} = 1.272$, $\alpha = 14.5$. The potentials were truncated and shifted at $r_{cut} = 2.5r_{m,ij}/\sqrt{2}$.

One of the predicted invariants on an isomorph is the structure of the system. To test this prediction, the radial distribution function in reduced coordinates $g(\tilde{r}) = g(\rho^{1/3}r)$ was plotted for isomorphic state points (Fig. 2a).

The structure is invariant for the large (A) particle pair correlation function to a very good approximation. For the AB and BB pairs the structure is less invariant. However, when a comparison is made with Figure 2b, it is clear that $g(\tilde{r})$ for the AB and BB pairs is still more invariant on an isomorph than on an isotherm (note that the density variation on the isomorph is larger than on the isotherm). This situation is similar to what is found for the KABLJ system [5].

To investigate the dynamics of the systems, the incoherent intermediate scattering function $F_s(q,t)$ is plotted in reduced units in Figures 3a and 3b. The presence of a plateau in $F_s$ shows that the system is in a viscous state,
when compared to the isotherm. In contrast to a non iso- morph where expressed in reduced units, especially when reduced units: $q = 7.25(\rho/1.2)^{1/3}$ and $q_B = 5.5(\rho/1.2)^{1/3}$. The solid lines represent isomorphic state points, while dashed lines show isothermal density changes for comparison. The dynamics are to a good approximation invariant on an isomorph when expressed in reduced units, especially when compared to the isotherm. In contrast to $g(\ell)$, this holds for both the A and the B particles.

![Fig. 3](image)

Fig. 3. (Color online) Incoherent intermediate scattering function for the A (a) and B (b) particles of the KABB system. The time is given in reduced units ($t = \rho^{1/3}T^{1/2}t$) and the $q$-vector is kept constant in reduced units: $q_A = 7.25(\rho/1.2)^{1/3}$ and $q_B = 5.5(\rho/1.2)^{1/3}$. The solid lines represent isomorphic state points, while dashed lines show isothermal density changes for comparison. The dynamics are to a good approximation invariant on an isomorph when expressed in reduced units, especially when compared to the isotherm. In contrast to $g(\ell)$, this holds for both the A and the B particles.

where the dynamics are highly state point dependent. The large difference in $F_\ell$ for the two isothermal state points confirms this (dashed lines). For the isomorph all $F_\ell$ data collapse more or less onto the same curve, showing that the dynamics are indeed invariant to a good approxima- tion on an isomorph. In contrast to the radial distribution functions, the invariance holds well for both types of particles.

To investigate the invariance in dynamics further, the coherent intermediate scattering function was calculated (Fig. 4). The coherent intermediate scattering function was calculated from the spatial transform of the number density $\rho(q)$ [7]. In order to obtain good results, it is necessary to average over time scales that are 10–15 times longer than what is usual for the intermediate scattering function. This is the reason that there are less state points shown for the coherent- than for the incoherent intermediate scattering function. The data confirm that the dynamics are invariant on the isomorph, especially when compared to the isothermal density change (dashed lines). However, the invariance seems to hold slightly better for the AB and BB parts, which is the opposite of what is seen for the structural invariance.

For systems described by a generalized LJ potential consisting of two IPL terms, the invariance of the structure leads to a prediction for the shape of an isomorph when plotted in the $U-W$ plane [6] (generalized LJ potentials are a sum of inverse power laws). Since the repulsive term in the Buckingham potential is described by an exponential function, it is not possible to derive an exact equation that describes the isomorph in terms of $U$ and $W$. Figure 5a shows that isomorphs for the KABB system agree well with the prediction for the 12–6 LJ system if $\alpha = 14.5$ (this value of $\alpha$ was chosen to demonstrate this feature). For $\alpha = 13.0$, there is a significant difference with the predicted shape at higher density and temperature. Figure 5b shows the isomorphs for both values of $\alpha$ after scaling $U$ and $W$ by the same isomorph-dependent factor, demonstrating the existence of a master isomorph [6]. This shows that master isomorphs exist not only in generalized LJ systems where they can be justified from analytical arguments [6].

![Fig. 4](image)

Fig. 4. (Color online) Coherent intermediate scattering function for different particle pairs on an isomorph in reduced units ($t = \rho^{1/3}T^{1/2}t$). The solid lines represent isomorphic state points, while dotted lines show isothermal density changes for comparison. Again, the $q$-vector is kept constant in reduced units: $q_{AA} = 7.34(\rho/1.2)^{1/3}$, $q_{AB} = 8.01(\rho/1.2)^{1/3}$ and $q_{BB} = 6.01(\rho/1.2)^{1/3}$. Also $F(q, \ell)$ is invariant on the isomorph. Contrary to what is seen for $g(\ell)$, the invariance holds better for the AB and BB parts.
4 The inverse-power-law (IPL) approximation

As mentioned in the introduction, a generic explanation [3–5] for the existence of strong correlations and isomorphs in non-IPL systems, is the fact that some pair potentials can be well approximated by an eIPL (Eq. (4)) as shown in Figure 6. Putting this explanation to the test, it was recently demonstrated that structure and dynamics of the KABLJ system can be reproduced by a purely repulsive IPL system even in the viscous phase [22]. In the following we demonstrate that this procedure works also for the KABB system, despite its non-IPL repulsion.

Following Pedersen et al. [22], we assume that the Kob-Andersen IPL (KABIPL) system used to approximate the KABB system has the form

\[ \psi_{\text{IPL}}(r) = A \epsilon_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^n \]  

where the parameters \( \epsilon_{ij} \) and \( \sigma_{ij} \) are the Kob-Andersen parameters for the different types of particles and the constants \( A \) and \( n \) are independent of particle type.

For IPL liquids it is known that \( W = (n/3)U \), so in principle the value of \( n \) could be calculated from \( \gamma \) determined from the \( WU \) fluctuations (Eq. (9)). For non-IPL liquids however, there is a slight state point dependence of \( \gamma \), so instead the slope of an isochore was used to determine \( n \) (Fig. 7a) making use of the identity [5]

\[ \gamma = \left( \frac{\partial W}{\partial U} \right)_V. \]  

For the Buckingham potential with \( \alpha = 14.5 \) we obtained \( \gamma = 4.904 \) and \( n = 14.71 \). This is lower than the \( \gamma = 5.16 \) which was found for the 12–6 LJ potential [22]. This is also consistent with the data in Figure 1b where the SCB system has a lower value of \( \gamma \) than the SCLJ system.

From equation (10) it follows that the total internal energy of the IPL system can be written as

\[ U^{\text{IPL}} = A \sum_{i>j} \epsilon_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^n. \]
calculate the excess isochoric specific heat using \[7\] and are in the same (supercooled) state.

The scaling factor \(A\) was determined from the slope of the mean values of the virial and the potential energy (marked by yellow crosses). (b) The method used to find the value of \(A\) of equation (12), \(U_IPL = \sum_{i>j} \epsilon_{ij}(\sigma_{ij}/r_{ij})^6\) was calculated from configurations drawn from the KABB simulations and plotted against the energy obtained during the simulations; the value of \(A\) was then obtained from the slope of the mean energies (again marked by yellow crosses).

The scaling factor \(A\) was determined from the slope of the mean values of the energies in a \(U, U_IPL\) plot (Fig. 7b), where \(U_IPL\) is given by equation (12) evaluated on configurations from simulations of the KABB mixture [22]. Using these parameters, simulations of the KABIPL systems were performed and the results were compared with the results of the KABB system. In Figure 8 the incoherent intermediate scattering function of the two systems is plotted for comparison. The KABIPL reproduces the dynamics of the KABB system very well. It should however be noted that in spite of the good reproduction of the dynamics, the KABIPL had a stronger tendency to crystallize than the KABB system at the two lowest temperatures due to the absence of attractive forces. The good agreement shown in Figure 8 only holds if both systems are in the same (supercooled) state.

From the fluctuations in the potential energy one can calculate the excess isochoric specific heat using [7]:

\[C_V^{ex} = C_V - \frac{3}{2} N k_B \frac{\langle (\Delta U)^2 \rangle}{k_BT^2}. \quad (13)\]

In Figure 9a \(C_V^{ex}\) is plotted for different isochors calculated from KABB and KABIPL simulations. The heat capacities for the two systems follow each other closely, although there is a small and systematic difference increasing with density. This is similar to what was found for the KABLJ system [22], but the deviations are slightly larger for the KABB mixture. Figure 9b shows that the excess heat capacity to a good approximation obeys density scaling, \(C_V^{ex}/N = f(\rho^5/T)\), and Rosenfeld-Tarazona scaling, again in good agreement with results for the KABLJ system [23].

5 Conclusion

The Buckingham potential has been shown to be strongly correlating like the Lennard-Jones potential. In spite of...
its exponential repulsion, the Buckingham potential’s dynamics and heat capacity can be closely approximated by a purely repulsive IPL system. In particular the system has good isomorphs in the phase diagram. These findings are very similar to those found for Lennard-Jones systems. We conclude that the existence of strong correlations and isomorphs is not dependent on the repulsion being an inverse power-law.

The centre for viscous liquid dynamics “Glass and Time” is sponsored by the Danish National Research Foundation (DNRF).
