Keywords: channel activation, CRISPR/Cas, endoplasmic reticulum (ER), N-linked glycosylation, protein translocation, transient receptor potential channels, TRP channels, post-translational modification, nonselective cation channel

ABSTRACT

Transient receptor potential cation channel subfamily C member 6 (TRPC6) is a widely expressed ion channel. Gain-of-function mutations in the human TRPC6 channel cause autosomal-dominant focal segmental glomerulosclerosis, but the molecular components involved in disease development remain unclear. Here, we found that overexpression of gain-of-function TRPC6 channel variants is cytotoxic in cultured cells. Exploiting this phenotype in a genome-wide CRISPR/Cas screen for genes whose inactivation rescues cells from TRPC6-associated cytotoxicity, we identified several proteins essential for TRPC6 protein expression, including the endoplasmic reticulum (ER) membrane protein complex (EMC) transmembrane insertase. We also identified transmembrane protein 208 (TMEM208), a putative component of a signal recognition particle (SRP)-independent (SND) ER protein-targeting pathway, as being necessary for expression of TRPC6 and several other ion channels and transporters. TRPC6 expression was also diminished by loss of the previously uncharacterized WD repeat domain 83 opposite strand (WDR83OS), which interacted with both TRPC6 and TMEM208. Additionally enriched among the screen hits were genes involved in N-linked protein glycosylation. Deletion of mannosyl (α-1,3-)glycoprotein β-1,2-N-acetylglucosaminyltransferase (MGAT1), necessary for generation of complex N-linked glycans, abrogated TRPC6 gain-of-function variant-mediated Ca2+ influx and extracellular signal-regulated kinase (ERK) activation in HEK cells, but failed to diminish cytotoxicity in cultured podocytes. However, mutating the two TRPC6 N-glycosylation sites abrogated the cytotoxicity of mutant TRPC6, and reduced its surface expression. These results expand the targets of TMEM208-mediated ER translocation to include multi-pass transmembrane proteins, and suggest that TRPC6 N-glycosylation plays multiple roles in modulating channel trafficking and activity.

TRPC6 is one of seven members of the canonical transient receptor potential (TRPC) subfamily of TRP channels (1,2). TRPC6 functions as a tetrameric non-selective cation channel (3), and assembles either as a homomer or as a heteromer with TRPC1, C3 or C7 (4-6). Activation and regulation of TRPC6 channel activity is complex and remains incompletely understood (7). TRPC6 is directly activated by diacylglycerol (3) and augmented by 20-hydroxyeicosatetraenoic acid (20-HETE) (8-10). It is best characterized acting downstream of Goq-
coupled receptors (11,12), but is also activated downstream of tyrosine kinases (13-15) and by reactive oxygen species (14,16-19). The ability of membrane deformation to activate TRPC6, directly (20) or indirectly (21), remains controversial (22) and may be cell type-specific (9,23-29). TRPC6 directly or indirectly mediates increases in intracellular calcium concentration (30-33), leading to activation of signaling pathways (34) that include calcineurin-NFAT (35-37), CREB (38-40), ERK (38), RhoA (41-43) and calpain-mediated proteolysis (44).

TRPC6 has a broad tissue and cell type expression profile, including smooth muscle cells, epithelial cells, endothelial cells, and immune cells (45,46). TRPC6 functions in animal and in vitro models (34) include differentiation, activation, and proliferation of myofibroblasts (47,48), modulation of organ fibrosis (49-50), promotion of pathologic cardiac hypertrophy (35,36) and pulmonary edema (51), modulation of glomerular diseases including diabetic nephropathy (52-56), promotion of neuronal survival and dendritic outgrowth (57,58), and regulation of leukocyte migration (59,60).

Human TRPC6 gene mutations are a cause of autosomal dominant focal segmental glomerulosclerosis (FSGS), a progressive glomerular kidney disease (61,62). Disease mutations are located within the cytoplasmic amino- or carboxyl- tails of the channel, predominantly in the ankyrin repeats and the coiled-coil sequences. Most mutations are reported to increase TRPC6-mediated current amplitude, delay channel inactivation and/or increase intracellular calcium levels (61-65). Other studies have reported disease-associated mutations impairing channel activity, at least in response to certain stimuli (64,66). Why TRPC6 mutations cause a renal-limited disease in humans despite the channel’s many reported functions in model systems remains unclear.

We do not yet know how the various disease-associated TRPC6 mutations cause a gain-of-function (GOF) phenotype. It has been suggested that mutations alter cell surface expression (15,61), although we (67) and others (68) have not found this to be the case. Cryo-EM structures demonstrate clustering of disease mutations at the interface between the ankyrin repeats and the carboxyl-terminal coiled-coil (69,70). This structure has prompted the hypothesis that the mutations alter allosteric gating, but confirmatory data is lacking. Although basal currents of TRPC6 GOF mutants are not of higher magnitude than those of the wild-type channel (67), they do lead to increased calcineurin-NFAT (67) and ERK (71) signaling in the absence of exogenous stimuli. We have hypothesized that some yet unidentified endogenous intermittent signal activates TRPC6 in this setting.

To better understand potential regulators of mutant TRPC6 and its downstream effects, we exploited the cytotoxic phenotype of cells overexpressing TRPC6 GOF mutants to perform a genome-wide CRISPR-Cas screen to identify genes whose inactivation rescued cells from cytotoxicity. The ER membrane protein complex (EMC), TMEM208 (recently identified as the mammalian homologue of SND2 (72)), and WDR83OS were revealed as necessary for effective expression of TRPC6 protein. Multiple enzymes involved in protein glycosylation were also identified as necessary for activity of TRPC6 GOF mutants. Loss of complex N-glycans on proteins due to MGAT1 deletion abolished TRPC6-mediated calcium influx without altering channel surface expression, whereas deletion of TRPC6 N-glycosylation sites diminished surface expression. In summary, TRPC6 expression requires the activities of two transmembrane insertases, while complex N-glycosylation of TRPC6 is required for TRPC6 channel function, but not for its surface expression.

Results
CRISPR/Cas screen utilizing the cytotoxicity of TRPC6 GOF mutants for selection
We considered that overexpression of TRPC6 with GOF mutations is detrimental to cellular survival or proliferation in light of unsuccessful attempts at generating stable cell lines constitutively expressing these mutant TRPC6 forms. Utilizing previously generated stable cell lines with inducible expression of wild-type or FSGS-mutant TRPC6 (67,71), we found enhanced cytotoxicity and impaired proliferation upon overexpression of GOF mutant, but not wild-type, TRPC6, as measured by cell count (Fig. 1A), MTT assay (Fig. 1B), and a cell viability/cytotoxicity assay (Fig. 1C).
CRISPR-screen identified genes necessary for TRPC6 function

Furthermore, we have been unable to maintain cultured podocytes transduced to express GOF TRPC6 mutants (data not shown), consistent with published data reporting enhanced podocyte apoptosis upon overexpression of GOF TRPC6 (73). CRISPR-Cas mediated knockout of TRPC6, but not PLCγ1 knockout or use of a no target control (NTC) single-guide RNA (sgRNA), abrogated the cytotoxic effect of tetracycline induction (Fig. 1D-F), suggesting that the cytotoxicity of GOF TRPC6 could be used in a positive selection CRISPR screen for genes that regulate TRPC6 function or toxicity.

We used a pooled library of lentiviral-encoded CRISPR-Cas sgRNAs (74) to identify genes necessary for the loss of cell viability induced by overexpression of the TRPC6 E897K GOF mutant (Supplemental Table 1). Three of the four sgRNAs targeting TRPC6 were enriched; the non-enriched sgRNA targets TRPC6 at a splice site, and is thus not predicted to target the cDNA construct driving TRPC6 GOF expression in our system. The top 63 gene hits identified in our screen using sgRSEA (single-guide RNA Set Enrichment Analysis) were entered into STRING (Search Tool for the Retrieval of Interacting Genes/Proteins; www.string-db.org). This generated a network (Fig. 2A) significantly enriched for protein-protein interactions (PPI enrichment p-value: <1.0 x 10^{-16}). Gene ontology (GO) process and component analysis identified enrichment of genes involved in N-linked glycosylation and in the ubiquitin-dependent endoplasmic reticulum-associated protein degradation (ERAD) pathway (75,76), and genes found in the nuclear outer membrane-endoplasmic reticulum membrane network and EMC (Fig. 2B). NCLN (Nicalin), NOMO1, and TMEM147, reported components of the Nodal Modulator Complex (77), as well as NOMO2 and NOMO3, were also among the screen hits. In validation experiments, we tested two sgRNA sequences distinct from those in the Brunello library (Table 1) for each of 12 screen hits for their ability to rescue cell viability upon induction of the TRPC6 R895C GOF mutant. These genes were chosen to represent various protein complexes or processes (EMC and ERAD pathways, N-linked glycosylation, the Nodal Modulator Complex), or because their potential mechanisms of action were unclear or of potential biological interest. A majority of these sgRNAs significantly enhanced cell viability following induction of TRPC6 R895C, as compared to a non-target control sgRNA (Fig. 2C).

To investigate the potential mechanism whereby knockout of these genes rescued cell viability, we examined TRPC6 protein levels (Fig. 2D). Guide RNAs targeting EMC2, EMC6, CCDC47, and TMEM208 substantially decreased TRPC6 protein levels. None of the tested sgRNAs significantly altered tetracycline induction of TRPC6 mRNA levels (Fig. 2E). The ability of the two WDR83OS sgRNAs to rescue cell viability correlated with their effect on reducing TRPC6 protein levels; testing several additional sgRNAs confirmed the association between loss of WDR83OS expression and decreased TRPC6 protein levels (Fig. 2F). However, we were unable to rescue TRPC6 expression by transfection of a WDR83OS expression construct (Fig. 2G), leaving in question this gene's status as a true modulator of TRPC6 expression. In contrast, the expression of a CRISPR-resistant TMEM208 construct rescued TRPC6 R895C expression in TMEM208 knockout cells (Fig. 2H), further validating TMEM208 as a modulator of TRPC6 protein levels. MGAT1 knockout significantly altered TRPC6 mobility on SDS-PAGE (Fig. 2D), consistent with the role of MGAT1 in generating hybrid and complex N-glycans (78).

The EMC and TMEM208 are each required for expression of multiple transmembrane proteins, but not for each other’s expression

The EMC is a 10-protein complex in mammalian cells (79) that functions as a transmembrane domain insertase, necessary for membrane insertion of tail-anchored proteins with moderately hydrophobic transmembrane domains (80) and for expression of various polytopic membrane proteins (81). In contrast, little is known about the function of TMEM208; it has been localized to the ER and implicated in regulation of autophagy and ER stress (82). We therefore explored the potential role of TMEM208 in modulating TRPC6 protein levels, and whether TMEM208 might be tied to EMC function. Expression of FLAG-TRPC6 is diminished in EMC2, EMC6 and TMEM208 knockout cells (Fig. 3A). EMC2 and EMC6

Furthermore, we have been unable to maintain cultured podocytes transduced to express GOF TRPC6 mutants (data not shown), consistent with published data reporting enhanced podocyte apoptosis upon overexpression of GOF TRPC6 (73). CRISPR-Cas mediated knockout of TRPC6, but not PLCγ1 knockout or use of a no target control (NTC) single-guide RNA (sgRNA), abrogated the cytotoxic effect of tetracycline induction (Fig. 1D-F), suggesting that the cytotoxicity of GOF TRPC6 could be used in a positive selection CRISPR screen for genes that regulate TRPC6 function or toxicity.

We used a pooled library of lentiviral-encoded CRISPR-Cas sgRNAs (74) to identify genes necessary for the loss of cell viability induced by overexpression of the TRPC6 E897K GOF mutant (Supplemental Table 1). Three of the four sgRNAs targeting TRPC6 were enriched; the non-enriched sgRNA targets TRPC6 at a splice site, and is thus not predicted to target the cDNA construct driving TRPC6 GOF expression in our system. The top 63 gene hits identified in our screen using sgRSEA (single-guide RNA Set Enrichment Analysis) were entered into STRING (Search Tool for the Retrieval of Interacting Genes/Proteins; www.string-db.org). This generated a network (Fig. 2A) significantly enriched for protein-protein interactions (PPI enrichment p-value: <1.0 x 10^{-16}). Gene ontology (GO) process and component analysis identified enrichment of genes involved in N-linked glycosylation and in the ubiquitin-dependent endoplasmic reticulum-associated protein degradation (ERAD) pathway (75,76), and genes found in the nuclear outer membrane-endoplasmic reticulum membrane network and EMC (Fig. 2B). NCLN (Nicalin), NOMO1, and TMEM147, reported components of the Nodal Modulator Complex (77), as well as NOMO2 and NOMO3, were also among the screen hits. In validation experiments, we tested two sgRNA sequences distinct from those in the Brunello library (Table 1) for each of 12 screen hits for their ability to rescue cell viability upon induction of the TRPC6 R895C GOF mutant. These genes were chosen to represent various protein complexes or processes (EMC and ERAD pathways, N-linked glycosylation, the Nodal Modulator Complex), or because their potential mechanisms of action were unclear or of potential biological interest. A majority of these sgRNAs significantly enhanced cell viability following induction of TRPC6 R895C, as compared to a non-target control sgRNA (Fig. 2C).

To investigate the potential mechanism whereby knockout of these genes rescued cell viability, we examined TRPC6 protein levels (Fig. 2D). Guide RNAs targeting EMC2, EMC6, CCDC47, and TMEM208 substantially decreased TRPC6 protein levels. None of the tested sgRNAs significantly altered tetracycline induction of TRPC6 mRNA levels (Fig. 2E). The ability of the two WDR83OS sgRNAs to rescue cell viability correlated with their effect on reducing TRPC6 protein levels; testing several additional sgRNAs confirmed the association between loss of WDR83OS expression and decreased TRPC6 protein levels (Fig. 2F). However, we were unable to rescue TRPC6 expression by transfection of a WDR83OS expression construct (Fig. 2G), leaving in question this gene's status as a true modulator of TRPC6 expression. In contrast, the expression of a CRISPR-resistant TMEM208 construct rescued TRPC6 R895C expression in TMEM208 knockout cells (Fig. 2H), further validating TMEM208 as a modulator of TRPC6 protein levels. MGAT1 knockout significantly altered TRPC6 mobility on SDS-PAGE (Fig. 2D), consistent with the role of MGAT1 in generating hybrid and complex N-glycans (78).

The EMC and TMEM208 are each required for expression of multiple transmembrane proteins, but not for each other’s expression

The EMC is a 10-protein complex in mammalian cells (79) that functions as a transmembrane domain insertase, necessary for membrane insertion of tail-anchored proteins with moderately hydrophobic transmembrane domains (80) and for expression of various polytopic membrane proteins (81). In contrast, little is known about the function of TMEM208; it has been localized to the ER and implicated in regulation of autophagy and ER stress (82). We therefore explored the potential role of TMEM208 in modulating TRPC6 protein levels, and whether TMEM208 might be tied to EMC function. Expression of FLAG-TRPC6 is diminished in EMC2, EMC6 and TMEM208 knockout cells (Fig. 3A). EMC2 and EMC6
proteins are each mutually dependent upon expression of the other (Fig. 3A), consistent with previous reports that knockout of one component of the EMC complex reduces expression of the entire complex (80). However, neither EMC component is affected by loss of TMEM208, nor is TMEM208 dependent upon expression of EMC2 or EMC6, suggesting that TMEM208 functions independently of the EMC. Expression of WDR83OS was not appreciably altered in any of the cell lines.

The expression of several additional transmembrane proteins was assessed in EMC- and TMEM208-deficient cells to address the possible requirement for TMEM208 and EMC genes for TRPC6 expression specifically, or for transmembrane protein expression in general (Fig. 3B, C). Expression plasmids encoding FLAG-tagged potassium channel KCN4/IK1 (Fig. 3B) and HA-tagged K-Cl cotransporter SLC12A4/KCC1 (Fig. 3C) were co-transfected with TRPC6 expression constructs into control (NTC) CRISPR treated cells or EMC2, EMC6 or TMEM208 knockout cells. Cytoplasmic red-fluorescent protein (RFP) expression plasmid was included as a control for transfection efficiency (Fig. 3B). Multi-membrane-spanning proteins KCN4 and SLC12A4 showed comparably poor expression in cells lacking either EMC component or TMEM208. In contrast, levels of the endogenous ER resident protein calnexin, a type 1 single transmembrane span protein, were not appreciably affected by loss of the EMC or of TMEM208. In sum, these results suggest that the EMC and TMEM208 are required for expression of diverse polytopic transmembrane proteins including TRPC6.

**TRPC6 interacts with TMEM208 and WDR83OS**

WDR83OS is a 106 amino-acid, predicted transmembrane protein of unknown function. Overexpressed, epitope-tagged TRPC6 and WDR83OS could be co-immunoprecipitated, and did not affect each other’s expression levels (Fig. 4A). WDR83OS lacking its carboxyl-terminal 27 amino acids, including a predicted transmembrane domain, was expressed at lower levels than full-length protein, but maintained its ability to immunoprecipitate TRPC6 (Fig. 4B). Interestingly, both WDR83OS constructs appear to preferentially interact with the lower molecular weight form of TRPC6, representing the immaturely N-glycosylated channel. A FLAG-tagged WDR83OS construct lacking amino acids 1-37 failed to produce detectable protein (data not shown).

FLAG-tagged TMEM208 was also capable of immunoprecipitating HA-TRPC6 when co-expressed (Fig. 4C). Truncated forms of TMEM208 lacking either the carboxyl-terminal 69 amino acids (including the predicted third transmembrane domain) or the amino-terminal 68 amino acids (including the predicted first two transmembrane domains) were still able to co-immunoprecipitate HA-TRPC6. However, compared to full-length TMEM208, the truncated mutants did not rescue TRPC6 expression as effectively when re-introduced into TMEM208 knock-out cells (Fig. 4D).

Interestingly, in addition to TRPC6, we detected endogenous WDR83OS in the FLAG-TMEM208 immunoprecipitates (Fig. 4C). To ensure that this interaction was not dependent upon the presence of overexpressed TRPC6, we repeated the experiments in the absence of overexpressed TRPC6 (Fig. 4E), with similar results. V5-tagged TMEM208 was also immunoprecipitated by full-length and carboxyl-truncated FLAG-WDR83OS (Fig. 4F). However, TMEM208 knockout did not affect WDR83OS protein levels (Fig. 3A, 4G), nor did WDR83OS knockout alter TMEM208 levels (Fig. 4G). Immunofluorescence microscopy demonstrated partial co-localization of overexpressed TRPC6, TMEM208, and WDR83OS in perinuclear and reticular patterns, intracellular structures suggestive of ER (Fig. 4H-J), providing evidence that these proteins have the opportunity to interact in vivo. Together, these results suggest that WDR83OS is a predominantly ER-localized protein capable of interacting with both TRPC6 and TMEM208.

**Lack of complex N-linked glycosylation impairs TRPC6 channel activity**

Differences in the N-linked glycosylation of TRPC3 and TRPC6 have been reported to account for their different basal channel activities (83). Specifically, elimination of the second extracellular loop N-glycosylation site of TRPC6 converted a tightly receptor-regulated channel to...
CRISPR-screen identified genes necessary for TRPC6 function

a constitutively active channel. We were therefore surprised that our screen identified numerous enzymes involved in N-linked glycosylation as potentially contributing to the toxicity of TRPC6 GOF mutants. Our initial efforts to examine this discrepancy have focused on the role of MGAT1, as knockout of this enzyme had the most robust effect on rescuing cell viability (Fig. 2C). We confirmed by enzymatic deglycosylation that the difference in TRPC6 mobility on SDS-PAGE observed in MGAT1 knockout cells reflects differences in N-glycosylation, and that mature TRPC6 glycosylation normally contains hybrid or complex N-glycans resistant to EndoH cleavage (Fig. 5A). Mutation of the two previously reported (83) N-glycosylation sites (N473 and N561) to glutamine (NN>QQ) abolished the difference in gel mobility of TRPC6 expressed in control or in MGAT1-deficient cells, and prevented further mobility shift upon PNGase treatment (Fig. 5B), confirming that these two asparagine residues are the only major sites of N-glycosylation in TRPC6. This allowed us to address whether the effects of MGAT1 knockout on TRPC6 functions are mediated directly through alterations in TRPC6 glycosylation, or might reflect impaired glycosylation of other endogenous proteins.

We assayed ERK phosphorylation as a surrogate marker of mutant TRPC6 activity, as we have previously demonstrated that TRPC6 GOF mutants activate ERK in a channel-dependent manner (71). Introduction of the double glycosylation mutation into TRPC6 R895C largely abrogated the channel's ability to increase phospho-ERK levels (Fig. 5C). TRPC6 R895C expressed in MGAT1 knockout cells also demonstrated little ability to activate ERK (Fig. 5D). However, TRPC6 R895C with immature glycosylation still slightly increased phospho-ERK levels compared to TRPC6 R895C NN>QQ (Fig. 5D; compare lanes 3 vs 4, and 5 vs 6).

To more directly ascertain the role of glycosylation on TRPC6 channel function, we examined intracellular calcium influx in response to the TRPC3 agonist, GSK1702934A (84,85). GSK1702934A induced an increase in Fura-2 fluorescence ratio in TRex293 cells expressing FLAG-TRPC6 R895C, but not in uninduced cells (Figure 6A, B). Compared to TRPC6 R895C cells with a no-target control (NTC) CRISPR construct, TRCP6 R895C cells with MGAT1 deletion showed a significantly diminished Fura-2 response to GSK1702934A. Whole cell voltage clamp experiments confirmed that TRPC6 R895C current densities in MGAT1 knockout cells were significantly lower than in control cells in response to agonist, but not at baseline (Fig. 6 C, D). Taken together, these results demonstrate that complex N-linked glycosylation is required for TRPC6 R895C-mediated channel activity and resultant calcium influx, ERK activation, and cytotoxicity.

Modulation of channel activity through regulation of surface expression has been reported for several TRPC channels, including TRPC6 (12,14,16,86-91). To test if glycosylation impacts surface expression of TRPC6, we compared surface biotinylation of TRPC6 R895C in control and MGAT1-deficient cells (Fig. 7A). As we previously reported (67), only the fully glycosylated, upper band of TRPC6 is expressed on the cell surface in control cells. However, the lower molecular weight form of TRPC6 present in MGAT1 knockout cells could be detected by surface biotinylation, with a similar ratio of surface-to-total TRPC6 R895C detected in control and MGAT1 knockout cells (Fig. 7B). We performed similar experiments comparing wild-type and the NN>QQ glycosylation-deficient TRPC6 transiently expressed in control NTC 293T cells (Fig. 7C, D). Unlike TRPC6 with immature N-glycans expressed in MGAT1-knockout cells, a significantly lower ratio of TRPC6 lacking N-glycosylation sites was available for surface biotinylation. This was not due to the R895C mutation itself, as the NN>QQ mutation diminished surface expression of TRPC6 R895C and wild-type TRPC6 to similar extents (Fig. 7C). These results suggest that some form of N-linked glycosylation is required for TRPC6 surface expression, whereas MGAT1-dependent hybrid or complex N-glycans are required for proper TRPC6 channel activity, but not for surface expression.

TRPC6 GOF cytotoxicity in podocytes requires TRPC6 N-linked glycosylation, but not MGAT1

Podocyte injury is a central driver of FSGS pathogenesis, and podocyte-specific overexpression of TRPC6 mutants induces mild
glomerular disease in mice (92). We therefore examined whether TRPC6 GOF mutations are also cytotoxic in an immortalized human podocyte cell line (93), and whether this phenotype is also dependent upon N-linked glycosylation. Human podocytes were transduced with lentiviral particles driving doxycycline-inducible expression of wild-type or R895C mutant TRPC6, with (NN) or without (QQ) N-linked glycosylation sites (Fig. 8A). Doxycycline-inducible, TRPC6 R895C expressing podocytes were further transduced with either control (NTC) or MGAT1-targeting LentiCRISPR virus (Fig. 8B). TRPC6 mobility shift served to confirm the efficient loss of MGAT1 activity. Expression of TRPC6 R895C, but not of wild-type TRPC6 or TRPC6 R895C lacking N-linked glycosylation sites, significantly decreased cell viability as assessed by MTT assay (Fig. 8C). CRISPR-mediated knockout of MGAT1, however, failed to significantly rescue the toxicity of TRPC6 R895C expression in podocytes (Fig. 8D), in contrast to its effect in HEK cells (Fig. 2C). In sum, these results suggest that TRPC6 GOF mutants are cytotoxic in a variety of cells, including podocytes, and that this phenotype is dependent upon TRPC6 N-linked glycosylation, but that the need for MGAT1-mediated complex glycans is cell-type specific.

Discussion

Previous studies have implicated numerous signaling cascades both upstream and downstream of TRPC6 channel activity. However, the role of these pathways in the potential adverse effects of TRPC6 GOF mutations remains unclear. Based on an unbiased, genome-wide CRISPR-Cas screen, we report here that efficient TRPC6 protein expression requires the expression of several proteins, including TMEM208, and components of the EMC complex. In addition, N-linked glycosylation of TRPC6 was found necessary at several stages for efficient TRPC6 function. Deletion of N-glycosylation sites limits surface expression of TRPC6, while blocking formation of hybrid and complex N-glycans through loss of MGAT1 impairs TRPC6 GOF-mediated current and calcium influx without reducing TRPC6 surface expression. Interestingly, dependence on MGAT1 function, but not on N-glycosylation, for TRPC6 GOF cytotoxicity appears to be cell type-specific. Together, these results advance our understanding of the requirements for proper TRPC6 channel expression and function, and establish multiple novel avenues for further investigation of TRPC6 channel regulation.

Multiple members of the EMC were identified in our screen of modulators of TRPC6 GOF toxicity, with validated hits EMC2 and EMC6 both necessary for effective TRPC6 expression. The EMC is an ER-resident multiprotein complex found in all eukaryotes (94). It functions as a transmembrane insertase required for the insertion and proper membrane topology of tail-anchored and multi-transmembrane proteins (80,95,96), including GPCRs, transporters and channels (81,97,98). Our results are in line with prior work (81) demonstrating that dPob/EMC is essential for TRP channel expression in the Drosophila eye.

Our data demonstrate a need for TMEM208 for the effective expression of TRPC6 and several additional polytopic transmembrane proteins. TMEM208 (hSnd2) and its yeast ortholog, Snd2, have been identified as members of an SRP-independent (SND) pathway that preferentially targets proteins with C-terminal transmembrane domains to the ER (72,99,100). Mammalian homologues of the other yeast Snd components, Snd1 and Snd3, remain undefined. Previous studies have largely focused on the importance of TMEM208 for ER translocation of carboxyl-terminal single transmembrane domain proteins (99,100). Our data suggest that TMEM208 is also required for the biosynthesis of several multi-pass transmembrane proteins, though delineation of the breadth of this TMEM208 requirement awaits further study. While loss of neither EMC2 nor of EMC6 affects TMEM208 protein levels, and loss of TMEM208 does not affect EMC2 or EMC6 levels, mass spectroscopy data suggest a physical interaction between Snd2 and EMC1 and EMC5 (72). Thus, TMEM208 and the EMC may cooperate in the ER membrane insertion of a variety of polytopic transmembrane proteins, including TRPC6.

WDR830S is a little studied gene that also emerged as a hit in our CRISPR screen. WDR830S is a ubiquitously expressed, predicted transmembrane protein evolutionarily conserved
in C. elegans and D. melanogaster. It is reported to interact with the Parkinson's disease P-type ATPase ATP13A2/PARK9 (101) and with the bile acid transporter ABCB11/BSEP (102). A homozygous splice site mutation in WDR83OS has been associated with a syndrome including hypercholanemia, intractable itching, intellectual disability, and dysmorphic features (103). While WDR83OS knockout affects TRPC6 protein levels, and WDR83OS can interact with both TRPC6 and TMEM208, our inability to rescue TRPC6 expression by overexpressing WDR83OS in WDR83OS knockout cells prevents definitive identification of this protein as required for TRPC6 function. It will be interesting to determine if WDR83OS knockout affects expression of other transmembrane proteins in addition to TRPC6, and to ascertain which sequences of TRPC6 are involved in binding to WDR83OS and TMEM208. In addition, the functional significance of the interaction between WDR83OS and TMEM208 will require an independent line of study.

A previous study has reported that N-linked glycosylation is necessary for the low basal ion channel activity of TRPC6 (83). In particular, the second extracellular loop N-glycosylation site (absent in the related TRPC3 channel characterized by higher basal activity) was found to mediate the tight receptor regulation of TRPC6. Deletion of this second glycosylation site, or of both glycosylation sites, did not prevent surface expression, but enhanced basal channel activity without significantly altering peak current densities after histamine stimulation (83). We were therefore surprised to find that preventing complex N-glycan formation through loss of MGAT1 significantly attenuated GSK1702934A-stimulated TRPC6 R895C current and channel-dependent calcium influx, as well as GOF mutant-induced ERK activation and cytotoxicity in HEK cells. Furthermore, mutating both N-glycosylation sites diminished TRPC6 surface expression and prevented TRPC6 GOF mutant-induced ERK activation, suggesting graded effects on the channel mediated by incomplete N-glycan maturation compared to a complete lack of glycosylation. This graded effect was most pronounced when examining the cytotoxic effect of TRPC6 R895C in podocytes. We cannot at present provide a satisfying synthesis of our results and those of Dietrich et al (83). Differences in experimental design, including the use of different mechanisms to activate the channel, the presence of the R895C mutation, and different overexpression methods, are potential factors contributing to the discrepant results. It is noteworthy that in addition to MGAT1, several additional genes involved in N-glycan formation were identified in our initial screen, including FUT8 and SLC35C1 involved in N-glycan fucosylation (104), supporting the notion that N-glycosylation directly or indirectly modulates TRPC6 activity.

We utilized the cytotoxic phenotype of overexpressed gain-of-function TRPC6 mutants to perform our screen agnostic as to the mechanism. We speculate that the cytotoxicity is due to calcium overload, as we have previously noted increased intracellular calcium levels in our Tet-inducible HEK cells (67,71), and calcium overload is known to activate multiple forms of cell death, including apoptosis and necrosis (105). The presence of FADD and TNFRSF10B in our initial list of screen hits suggests death receptor-mediated apoptotic signaling (106) may be involved. These hypotheses are being tested by ongoing experiments. Ultimately, the question of whether TRPC6 GOF-mediated cytotoxicity is involved in the development of FSGS will require testing in a robust model of the disease, one currently unavailable.

In summary, exploiting the cytotoxic effects of overexpressed TRPC6 GOF mutants, we have identified several biological processes necessary for TRPC6 expression and function. In addition to an expected role for EMC in TRPC6 expression, we have identified TMEM208 as a necessary factor for the expression of several polytopic transmembrane proteins, including TRPC6, thus expanding the role of the human homologue of SND2. Our results further suggest that N-glycosylation plays a critical role in TRPC6 function, affecting both surface expression and ion channel function. These findings imply a more complex role for glycosylation in the function and regulation of TRPC6 than previously envisioned. In addition, it is tempting to speculate that tissue or cell-type specific glycosylation may influence channel activity, possibly thus contributing to the renal-limited phenotype of human TRPC6 mutations.
A more detailed examination of these hypotheses will be the focus of future studies.

**Experimental procedures**

**Reagents and Plasmids** - TRex293 (Invitrogen) stable cell lines expressing FLAG-tagged TRPC6 wild-type, R895C, and E897K mutant channels were previously described (67), as were amino-terminal FLAG- and HA-tagged TRPC6 expression constructs (71). Conditionally immortalized human podocytes were maintained as previously described (93). Lentiviral transduction - HEK293T cells (ATCC CRL-3216) were transiently transfected using X-tremeGENE 9 with psPAX2, pCMV-VSV-G and either LentiCRISPR v2 or pCW57 constructs in a 2:1:3 weight/weight ratio. After 6 hours, fresh media was applied. Conditioned media containing viral particles was collected and cleared by centrifugation every 24 hours for 2 days. Human podocytes were transduced by incubating with virally conditioned media and hexadimethrine bromide (8 µg/ml) overnight, followed by selection with either 30 µg/ml blasticidin or 1 µg/ml puromycin.

**Cell proliferation and cytotoxicity studies** - Freshly trypsinized cells were counted and plated as indicated. Cells were cultured in complete media in the absence or presence of 50 ng/ml tetracycline, or 1 µg/ml doxycycline to induce TRPC6 expression. For assessment of cell viability by MTT, cells were plated at 5x10^3 cells per well in a 96-well plate and grown with or without tetracycline, or doxycycline, in complete media for 96 hours. Media were replaced with dye-free complete media containing MTT (0.5 mg/mL), and cells were incubated at 37°C for three hours. After removal of media, MTT crystals were solubilized in 0.1 N HCl in isopropanol, and absorbance was measured at 570 nm with background at 660 nm (SpectraMax5, Molecular Devices). For cytotoxicity and viability measurements using the MultiTox-Fluor Multiplex Cytotoxicity assay (Promega), 10^5 cells were plated per well of a 96-well plate and grown with or without tetracycline in complete media for 24 hours. Toxicity was then assayed per the manufacturer’s protocol.

**Genome-wide CRISPR screen** - Lentivirus containing the Brunello human CRISPR Knockout pooled plasmid library (74) in the lentivirus backbone was obtained from Addgene (#73178-LV). The positive selection screen and amplification of integrated sgRNA sequences were performed as outlined in (74) with minor adjustments. Briefly, stable Tet-induced TRPC6 E897K expressing TRex 293 cells (67) were first transduced with lentiCas9-
Blast. Approximately 9x10^7 cells were then infected with the Brunello CRISPR knockout library at an MOI of 0.35, followed by selection with puromycin (1 µg/mL). This provided an estimated representation of 400 cells per sgRNA. After 7 days of puromycin selection cells were trypsinized, and ~25% of the cell population (8.5 x 10^7 cells) was harvested for Next Generation Illumina sequencing. The remainder (2.6 x 10^8 cells) was treated with tetracycline (50 ng/mL) to induce TRPC6 E897K expression, resulting in a cytotoxic phenotype. After two weeks culture in the presence of TRPC6 E897K induction, surviving cells were harvested and genomic DNA isolated. Guide RNA amplification, and preparation for sequencing was performed using established protocols (74). Next Generation Sequencing was performed on an Illumina MiSeq machine. Read mapping and sgRNA enrichment was performed using the online CRISPRAnalyzeR (http://crispr-analyzer.dkfz.de/).

Validation of CRISPR screen hits - CRISPR knockout cells were made for each of the target genes chosen for further study. TRex293 cells expressing tet-inducible mutant TRPC6 R895C were transfected with the lentiCRISPR v2 plasmid containing one of two distinct sgRNAs for the target gene, followed by selection with puromycin (2 µg/mL). To confirm rescue of the TRPC6 R895C-induced cytotoxic phenotype, the CRISPR KO TRPC6 R895C cells were treated with tetracycline to induce TRPC6 R895C expression for 90h. Cell viability was quantified by MTT assay. FLAG-TRPC6 expression was evaluated by Western blot.

Calcium fluorescence ratio measurement - TRPC6 channel activity was assessed by Fura-2 fluorescence ratio measurement of intracellular calcium ion (Fura-2 QBT kit, Molecular Devices #R8197) in a 96-well format on a FlexStation 3 microplate reader with automated pipetting at the Harvard ICCB-Longwood screening facility. Cells were incubated with the Fura-2 dye for 1 hour at 37°C, then excited every 5 sec at wavelengths of 340 nm and 380 nm, with Fura-2 fluorescence emission read at 510 nm. Agonist or vehicle carrier was added after 30 seconds. Digitonin was added at the end of every experiment as a positive control for dye loading.

Electrophysiology – FLAG-TRPC6 R895C-expressing TRex293 stable cell lines transfected with control or MGAT1-targeting LentiCRISPR were grown on coverslips and mounted on an inverted microscope in a 200 µl open chamber (WPI, Sarasota, FL). Patch pipettes of resistance 1.5-3 MΩ were filled with a solution consisting of (in mM): 140 Cs methanesulfonate, 10 EGTA, 10 HEPES, 2.27 MgCl2, 1.91 CaCl2, and 1 Na ATP; pH 7.2 with CsOH. The bath solution contained (in mM): 145 NaCl, 5 KCl, 1 MgCl2, 2 CaCl2, 10 HEPES and 10 glucose; pH 7.4 with NaOH. Whole cell patch currents were recorded (Axopatch 200, Molecular Devices, Sunnyvale, CA) and digitized with a 1550B AD/DA board (Molecular Devices). To determine current-voltage relationships (I-V curves) in Clampex (pClamp11, Molecular Devices), a 500 ms ramp protocol from +100 to -100 mV was repeated every 10 seconds for the duration of the experiment (111). The bath reference electrode was a silver chloride wire with a 3 M KCl agar bridge. Data were filtered at 500 Hz, digitized at 10 kHz by Clampex, and analyzed offline by Clampfit subroutine (pClamp11). Holding potentials in whole cell patch experiments were expressed as V_h, the pipette potential. The ramp current measured at -60 mV was chosen to report whole cell conductance.

Immunoprecipitation and Western blotting – Experiments were performed essentially as previously described (71). After removing media and rinsing cells in cold PBS, cells were lysed in Tris-buffered saline (50 mM Tris-HCl, pH 7.4; 150 mM NaCl) containing 1% (v/v) NP-40, EDTA-free Complete protease inhibitor, and PhosStop (Roche Applied Sciences). Lysates were cleared by centrifugation at 17,000 x g for 15 minutes at 4°C. An aliquot was mixed with 4x SDS-sample loading buffer with β-mercaptoethanol, incubated at 95°C for 5 min, and used to assay protein expression by Western blot. For immunoprecipitation, cleared lysates were incubated with 20 µl of FLAG M2 or anti-HA-agarose slurry and incubated with constant agitation at 4°C for 2–3 h. Immunoprecipitated complexes were washed three times with lysis buffer and eluted by boiling in SDS sample loading buffer.
Mini-PROTEAN TGX and Tris/Tricine gels (Bio-Rad) were utilized for SDS-PAGE, followed by transfer onto PVDF membrane for immunoblotting as previously described (71). Surface biotinylation assay - Cells were washed with HBSS and incubated with 1 mg/mL Sulfo-NHS-SS-Biotin (Thermo Scientific #21331) at 4°C for 1 hour. The reaction was quenched with 5 mM Tris in HBSS, and cells were lysed in TBS 1% NP-40. Lysate was incubated with streptavidin-agarose beads at 4°C for 2 hours. Beads were washed, and biotinylated protein was eluted in sample loading buffer for Western blot. TRPC6 glycosylation mutants - The two known TRPC6 N-glycosylation sites (N473 and N561) were mutated to glutamine residues in the FLAG-hTRPC6 expression constructs using the QuikChange II XL Site-Directed Mutagenesis kit (Agilent Technologies #200521). Successful mutation was confirmed by Sanger sequencing. FLAG-TRPC6 wild-type or NN>QQ mutant was transfected into CRISPR NTC cells or into CRISPR MGAT1 knockout 293T cells. Differences in TRPC6 glycosylation were visualized by mobility shift on SDS-PAGE. Western blot was also used to identify alterations in p-ERK levels. Immunocytochemistry - HeLa cells were transfected with expression plasmids encoding FLAG-TRPC6, V5-WDR83OS or FLAG-WDR83OS, and V5-TMEM208. After 24 hours, cells were fixed in 4% paraformaldehyde and 4% sucrose in PBS, and permeabilized at room temperature with 0.3% Triton-X 100 in PBS. Cells were blocked with PBS containing 2% FBS, 2% BSA, 0.2% fish gelatin for 1 hour, followed by 2 h incubation with primary antibody directed against FLAG and V5. After rinsing, cells were incubated with secondary antibody for 1 hour before mounting. Confocal images were obtained on a Zeiss LSM510 upright confocal system at the Beth Israel Deaconess Confocal Imaging Core.

Figure 1. TRPC6 gain-of-function mutations are cytotoxic. A-C, equal numbers of TRex293 cells expressing the indicated tetracycline-inducible FLAG-TRPC6 construct were grown in the absence (open bars) or presence (shaded) of tetracycline. A, cells were trypsinized and counted after 90 hours of growth. B, colorimetric MTT assay was performed to compare metabolic activity after growth for 72 hours. C, relative cytotoxicity:viability ratio of the indicated TRPC6-expressing cells after 24 hours of induction. D-F. Tetracycline-inducible TRPC6 R895C-expressing cells were transfected with LentiCRISPR constructs encoding sgRNAs either with no target (NTC) or targeting TRPC6 or PLCγ1; two different sgRNA sequences were tested for each target. FLAG-TRPC6 expression was induced with tetracycline as indicated. D, expression of TRPC6, PLCγ1 and tubulin was assayed by Western blot. Cell count (E) and MTT assay (F) were performed after 72 hours of tetracycline induction. Shown are means ±SD and individual values. Statistical analysis was performed using two-way ANOVA with Tukey’s multiple comparisons test (C) or multiple t-testing using the Holm-Sidak method; **, p<0.01; ***, p<0.001; ns, p>0.05.
Figure 2. CRISPR screen identifies genes necessary for TRPC6 GOF cytotoxicity. A, protein-protein interaction network generated by STRING analysis utilizing the top 63 gene hits identified in the CRISPR screen. Only genes demonstrating at least one high confidence interaction with another hit are displayed.
CRISPR-screen identified genes necessary for TRPC6 function

B, false discovery rate (FDR) for cellular processes and components most overrepresented among the top CRISPR hits, as defined by gene ontology. C-E, tetracycline-inducible TRPC6 R895C-expressing cells were transfected with LentiCRISPR constructs encoding either no target control sgRNAs (NTC) or sgRNAs targeting the indicated genes identified in the screen. Two independent sgRNAs were tested per gene. Antibiotic-selected cells were grown in the absence or presence of tetracycline to induce FLAG-TRPC6 R895C expression. C, relative cell viability, calculated as the ratio of live cells cultured in the presence vs. absence of tetracycline for 96 hours. Bar shading groups genes found in a complex or involved in a particular biological process. D, Western blot analysis of FLAG-TRPC6 R895C expression after tetracycline induction in the indicated CRISPR cell lines. Tubulin served as a loading control. E, qPCR analysis of GAPDH-normalized TRPC6 RNA expression after tetracycline induction in the indicated CRISPR cell lines, as compared to NTC cells grown in the absence or presence of tetracycline. One-way ANOVA analysis with Dunnett’s multiple comparisons test compared to NTC with tetracycline; ****, p<0.0001; n.s., not significant. F, Western blot analysis of FLAG-TRPC6 R895C, WDR83OS and actin in cells transfected with control NTC CRISPR construct or four distinct WDR83OS targeting CRISPR constructs. Loss of FLAG-TRPC6 expression correlated with the degree of WDR83OS knockout achieved. G, tetracycline-inducible TRPC6 R895C-expressing cells transfected with LentiCRISPR constructs encoding sgRNAs with either no target (NTC) or targeting two distinct sequences in WDR83OS (WDR83OS 1 and 4) were transfected with empty vector (EV) or plasmid encoding CRISPR-resistant HA-tagged WDR83OS as indicated. Cell lysates were subject to immunoblotting after treatment without or with tetracycline (+Tet) as indicated. Transfection of HA-WDR83OS plasmid produced WDR83OS protein levels higher than endogenous levels seen in NTC cell lines, but failed to significantly alter FLAG-TRPC6 protein levels. H, control NTC CRISPR (TMEM KO -) or TMEM208 CRISPR knockout (TMEM KO +) TRPC6 R895C inducible cells were transfected with plasmid encoding a CRISPR-resistant V5-tagged TMEM208 construct (+) or empty vector (-) as indicated, followed by tetracycline-induction of TRPC6 expression. Cell lysates were analyzed by Western blot for expression of FLAG-TRPC6, TMEM208 and β–actin. V5-tagged TMEM208 (open arrowhead) runs as a slightly higher band than endogenous TMEM208 (solid arrowhead). The asterix marks a non-specific band.
Figure 3. EMC and TMEM208 are necessary for expression of a variety of multi-pass transmembrane proteins. A, FLAG-TRPC6 R895C expression was induced by tetracycline in cells with CRISPR-mediated knockout of EMC2, EMC6 or TMEM208, or expressing control sgRNA (NTC). Western blot analysis demonstrates that FLAG-TRPC6 expression is dependent upon each of these three genes (top panel). In contrast, EMC2 and EMC6 expression are dependent on each other, but not on TMEM208, whereas TMEM208 protein levels are not altered by loss of either EMC component. Levels of endogenous WDR83OS were not appreciably different in these cell lines. Asterisks mark non-specific bands. B, cells with CRISPR-mediated knockout of the genes indicated at the top of the panel were co-transfected with expression constructs for HA-tagged wild-type TRPC6, FLAG-tagged KCNN4, and RFP. Expression of the indicated proteins was then analyzed by Western blotting equal amounts of cell lysates. RFP was used as a control for transfection efficiency. C, the same CRISPR-modified cells as in (B) were co-transfected with expression constructs for FLAG-TRPC6 and HA-tagged SLC12A4/KCC1, lysed and analyzed by Western blot using the indicated antibodies. Endogenous calnexin was examined as a model single-pass type 1 transmembrane protein; actin served as a loading control.
Figure 4. TRPC6, WDR83OS, and TMEM208 interact with each other. A, HEK 293T cells were transfected with HA-tagged wild-type TRPC6 and FLAG-tagged WDR83OS as indicated, lysed and subjected to immunoprecipitation with anti-FLAG or anti-HA antibody. Whole lysates, and the FLAG and HA immunoprecipitates (IP) were probed with antibody against HA, WDR83OS and β-actin as indicated. The arrowhead marks endogenous WDR83OS. B, cells were transfected with HA-tagged TRPC6, and either full-length (1-106) or carboxyl-terminal truncated (1-79) FLAG-tagged WDR83OS as shown. Cell lysates and anti-FLAG immunoprecipitates were analyzed by SDS-PAGE followed by Western-blotting with HA or FLAG antibody as indicated. C, HEK cells were transfected with HA-TRPC6 and empty vector (-) or various FLAG-tagged TMEM208 constructs, including full-length TMEM208 (1-173), a carboxyl-terminal truncated construct (1-104), and an amino-terminal truncated form (69-173). Cell lysates and FLAG IP samples were subject to SDS-PAGE and Western-blotting with the indicated antibodies. Endogenous WDR83OS was detected in lysates and FLAG-TMEM208 immunoprecipitates. D, HEK cells were transfected with LentCRISPR v2 plasmids encoding control (NTC) or TMEM208-targeting sgRNA as indicated (sgRNA). These cells were then transfected with
plasmids encoding HA-TRPC6 and various FLAG-TMEM208 constructs as in (C), lysed and analyzed by SDS-PAGE followed by Western blotting (WB) with the indicated antibodies. Co-expression of full-length (1-173) FLAG-TMEM208 rescued TRPC6 expression in the TMEM208 knockout cells to a greater extent than did the carboxyl- (1-104) or amino- (69-173) truncated FLAG-TMEM208 constructs. The arrowhead in the middle panel marks endogenous TMEM208 present in control (NTC) CRISPR cells. E, lysates and FLAG immunoprecipitated material from HEK cells transfected with the indicated FLAG-TMEM208 expression constructs were subjected to SDS-PAGE and Western blot with anti-FLAG and anti-WDR83OS antibodies as indicated. Endogenous WDR83OS was detected in all FLAG-TMEM containing immunoprecipitates, but not in immunoprecipitates from cells transfected with empty vector (-). F, V5-TMEM208 was transfected into HEK cells with control vector (-), full-length (1-106) FLAG-WDR83OS or carboxyl-terminal truncated (1-79) FLAG-WDR83OS. Lysates and FLAG IP material were analyzed by Western blotting with antibodies against the FLAG-epitope or TMEM208 (TMEM) as indicated. G, HEK cells were transfected with LentiCRISPR v2 plasmids encoding sgRNAs without a target (NTC), targeting TMEM208 (TMEM) or targeting two different sequences of WDR83OS (WDR-1 and WDR-4). Cell lysates were subjected to SDS-PAGE and Western blot using the indicated antibodies. TMEM208 is highlighted by an arrowhead; the asterix marks a non-specific band. Tubulin served as a loading control. H-J, immunofluorescence microscopy of HeLa cells transiently transfected with (H) FLAG-TRPC6 and V5-TMEM208, (I) FLAG-TRPC6 and V5-WDR83OS, and (J) FLAG-WDR83OS and V5-TMEM208. Individual channels are shown in the left and middle panels; the composite image is shown on the right (merge). Scale bar denotes 10 µm.
Figure 5. N-linked glycosylation of TRPC6 R895C. A, Western blot analysis of tet-inducible FLAG-TRPC6 R895C-expressing cells with a control CRISPR sgRNA (NTC) or with MGAT1-knockout mediated by one of two sgRNAs. Lysates were treated as indicated with EndoH (to remove immature N-glycans), PNGaseF (to remove all N-glycans) or mock-treated prior to SDS-PAGE. B, FLAG-TRPC6 R895C or FLAG-TRPC6 R895C carrying mutations of both N-glycosylation sites, N473Q and N561Q, (NN>QQ) was expressed in two control (NTC) and two MGAT1 knockout cell lines. Lysates were subjected to PNGaseF treatment as indicated prior to SDS-PAGE and Western blot analysis. C, HEK cells transiently expressing FLAG-TRPC6 carrying the indicated mutations were lysed and subjected to Western blotting with the indicated antibodies. The increase in phospho-ERK levels induced by the R895C mutation was largely abrogated by the dual glycosylation site mutation. D, Western blot analysis of two control (NTC) and two MGAT1 knockout cell lines expressing FLAG-TRPC6 R895C with (NN) or without (QQ) N-glycosylation sites.
Figure 6. MGAT1 knockout diminishes TRPC6 R895C-mediated calcium influx and whole cell current in response to GSK1702934A.

A, time-course of Fura-2 fluorescence ratio in TRex293 FLAG-TRPC6 R895C cells. Control CRISPR (NTC) or MGAT1 knockout (MGAT1) cells were treated with or without tetracycline to induce TRPC6 expression as indicated prior to Fura2 imaging. GSK1702934A (final concentration 100µM) or DMSO vehicle control (no stim) was added after 30 seconds to activate TRPC6. Shown are mean ± SD from n=10-12 experiments performed on 3 different days. B, peak post-stimulation Fura2 fluorescence ratios from fluorescence traces shown in (A); shown are the mean and values from individual experiments. One-way ANOVA with Sidak’s multiple comparison test; **, p<0.005; *, p<0.05; ††††, p<0.0001 vs. all other groups. C, I-V curves before (dashed line) and after GSK1702934A (solid line) stimulation of representative individual TRex293 FLAG-TRPC6 R895C cells with control CRISPR (NTC) or MGAT1 knockout (MGAT1). D, baseline and GSK1702934A stimulated peak current density measured at -60 mV. Shown are the mean and values of each individual cell; two-way ANOVA with Sidak’s multiple comparison test; **, p<0.005 versus all other groups; all other pairwise comparisons not significant; n=7 per group.
Figure 7. Surface expression of TRPC6 glycosylation mutants. A, control (NTC) or MGAT1 knockout (MGAT1) cells expressing tet-inducible FLAG-TRPC6 R895C were subjected to surface biotinylation. FLAG Western blot analysis was performed on streptavidin-precipitates and whole lysate. B, ratios of surface-accessible-to-total FLAG-TRPC6 R895C in control and MGAT1 knockout cells; n=7-8; unpaired t-test, p=0.943. C, FLAG-tagged wild-type (WT) or R895C mutant TRPC6 with intact (NN) or mutant (QQ) N-linked glycosylation sites was transiently expressed in control NTC cells. Surface-biotinylated protein was isolated by streptavidin precipitation and compared to whole lysate by Western blotting. Actin served as a loading control and as a negative control for surface biotinylation. D, ratios of surface-accessible-to-total FLAG-TRPC6 WT and NN>QQ glycosylation mutant expressed in control (NTC) 293T cells; n=6 per group; paired t-test, p=0.0049.
Figure 8. Role of N-linked glycosylation and MGAT1 function in TRPC6 R895C-mediated cytotoxicity in podocytes. A, Western blot analysis of podocytes transduced with lentivirus constructs driving doxycycline-inducible expression of wild-type (WT) or R895C mutant TRPC6 with intact (NN) or mutant (QQ) N-linked glycosylation sites. TRPC6 expression was induced by addition of doxycycline in all samples except the first lane (-Dox). Actin served as a loading control. B, doxycycline-inducible TRPC6 R895C-expressing podocytes were transduced with LentiCRISPR virus with a no target control (NTC) sgRNA or sgRNA targeting MGAT1. Lysates from cells grown in the absence or presence of doxycycline were analyzed by Western blot for TRPC6 and actin. C, relative cell viability, measured as MTT assay absorbance from doxycycline-induced cells relative to uninduced cells. Podocytes expressing wild-type TRPC6 (WT), N-linked glycosylation mutant TRPC6 (NN>QQ), TRPC6 R895C mutant with intact (R895C) or mutated (R895C NN>QQ) glycosylation sites, as shown in (A) were examined. Shown are mean ± SD as well as individual means from each of three independent experiments; one-way ANOVA with Tukey’s multiple comparisons test; **, p<0.005 versus all other cell lines; all other comparisons not statistically significant. D, relative cell viability, measured as in (C), of control or MGAT1-knockout podocytes expressing TRPC6 R895 (as in B). Means ± SD, as well as individual means from each of three independent experiments, are shown; n.s., p=0.33 by two-tailed, paired t-test.
Transmembrane insertases and N-glycosylation critically determine synthesis, trafficking and activity of the nonselective cation channel TRPC6
