We construct the coordinate Bethe ansatz for all eigenstates of the open spin-$\frac{1}{2}$ XXZ chain that fulfill the phantom roots criterion (PRC). Under the PRC, the Hilbert space splits into two invariant subspaces and there are two sets of homogeneous Bethe ansatz equations (BAE) to characterize the subspaces in each case. We propose two sets of vectors with chiral shocks to span the invariant subspaces and expand the corresponding eigenstates. All the vectors are factorized and have symmetrical and simple structures. Using several simple cases as examples, we present the core elements of our generalized coordinate Bethe ansatz method. The eigenstates are expanded in our generating set and show clear chirality and certain symmetry properties. The bulk scattering matrices, the reflection matrices on the two boundaries and the BAE are obtained, which demonstrates the agreement with other approaches. Some hypotheses are formulated for the generalization of our approach.

PACS numbers:

INTRODUCTION

Quantum integrable systems [1–3] play important roles in various fields such as low-dimensional condensed matter physics, quantum field theory, statistical physics and Yang–Mills theory. Many methods have been developed for the analysis of integrable systems. Among them, the two most classic ones are the coordinate Bethe ansatz and the algebraic Bethe ansatz (ABA). The usage of the conventional coordinate Bethe ansatz and ABA has so far been restricted to one-dimensional integrable systems with $U(1)$ symmetry that guarantees the existence of some obvious reference states. For integrable systems without $U(1)$ symmetry, there are no obvious reference states and the conventional BA fails. Several methods including Baxter’s $T$-$Q$ relation [1] and Sklyanin’s separation of variables (SoV) method [4] have been developed to approach this remarkable problem.

In this paper we focus on the XXZ spin-$\frac{1}{2}$ chain with open boundaries. The non-diagonal boundary fields break the $U(1)$ symmetry which makes the problem of constructing Bethe vectors rather unusual. It was proved in [5–7] for the boundary parameters obeying a certain constraint, that the modified ABA can be applied and homogeneous conventional $T$-$Q$ relations exist. The eigenvalue problem of the open XXZ spin chain with generic integrable boundary conditions was first solved via the off-diagonal Bethe ansatz (ODBA) method [8, 9]. The Bethe-type eigenstates were then retrieved in [10] based on the ODBA solution and a convenient SoV basis [11–13]. Although the analytical form of the Bethe state with generic or constrained boundaries has been given, little is known about their inner structure.

In our recent papers [14, 15], we studied the eigenstates of the open XXZ chain under the phantom roots criterion (PRC). The PRC is equivalent to the constrained boundary condition proposed in [5, 6]. The PRC restricts the system parameters to a set of manifolds parameterized by an integer number $M$ but does not introduce any obvious symmetry like $U(1)$ symmetry. Under the PRC, the Hilbert space splits into two invariant subspaces whose dimensions are determined by the integer $M$. Two sets of factorized chiral states are selected here to span the subspaces respectively. In [14, 15] we constructed the phantom Bethe states in some simple cases and analyzed their properties such as the chirality and the corresponding spin current.

In this paper, the coordinate Bethe Ansatz method is generalized in full detail. Here we report on a formulation of “generalized” chiral coordinate Bethe ansatz (CCBA) in an open XXZ spin chain with non-diagonal boundary fields. We do this on the example of the system satisfying the PRC.

Our approach inherits the core ideas of conventional coordinate Bethe ansatz method and gives novel results. The novelty is two-fold: (i) we find that it is appropriate to use the basis vectors with chiral shocks, instead of the usual conventional computational basis; for this reason we also call it a chiral Bethe ansatz (ii) it turns out to be appropriate to enlarge the basis into a symmetric one by including linearly-dependent “auxiliary” vectors.

The paper is organized as follows. First, we introduce the open XXZ spin-$\frac{1}{2}$ chain under the phantom roots conditions. Two symmetrically enlarged sets of vectors are then constructed based on which we can expand the phantom eigenstates of the Hamiltonian. Next, we demonstrate how the chiral coordinate Bethe ansatz works in terms of these vectors for the $M = 0, 1, 2$ cases and generalize our method to the arbitrary $M$ case. In the last part of the main text, we specifically study the spin helix eigenstates. Some necessary proofs are given in the Appendices.

THE OPEN XXZ MODEL UNDER PHANTOM ROOTS CONDITIONS

We study the spin-$\frac{1}{2}$ XXZ chain with open boundary conditions

...
\[
H = \sum_{n=1}^{N-1} h_{n,n+1} + h_1 + h_N, \tag{1}
\]
where
\[
h_{n,n+1} = \sigma_n^x \sigma_{n+1}^x + \sigma_n^y \sigma_{n+1}^y + \cosh \eta \sigma_n^z \sigma_{n+1}^z - \cosh \eta I, \tag{2}
\]
\[
h_1 = \frac{\sinh \eta}{\sinh(\alpha_- \cosh(\beta_+))} \left( \cosh(\theta_-) \sigma_1^x + i \sinh(\theta_-) \sigma_1^y + \cosh(\theta_-) \sinh(\beta_-) \sigma_1^z \right), \tag{3}
\]
\[
h_N = \frac{\sinh \eta}{\sinh(\alpha_+ \cosh(\beta_+))} \left( \cosh(\theta_+) \sigma_N^x + i \sinh(\theta_+) \sigma_N^y - \cosh(\alpha_+) \sinh(\beta_+) \sigma_N^z \right), \tag{4}
\]
and \(\alpha_\pm, \beta_\pm, \theta_\pm\) are boundary parameters. We parameterize the anisotropy parameter of the exchange interaction as \(\Delta \equiv \cosh \eta \equiv \cos \gamma\) with \(\eta = i \gamma\).

This model is one of the most famous integrable systems [1, 2, 16, 17] without \(U(1)\) symmetry. The exact solutions of this model have been given by the ODBA method [8, 9]. A set of inhomogeneous Bethe ansatz equations (BAE) with at least \(N\) Bethe roots were constructed \([8–10]\) to solve the eigenvalue problem and the Bethe-type eigenstates were then retrieved \([9, 10]\) based on the ODBA solution.

An interesting observation is that some Bethe roots in the original inhomogeneous BAE can be chosen “phantom”, i.e. with infinite value of the root and hence not contributing to the energy, under some specific conditions like
\[
(N - 2M - 1) \eta = \alpha_- + \beta_- + \alpha_+ + \beta_+ + \theta_- - \theta_+ \mod 2\pi i. \tag{5}
\]
where \(M\) is an integer ranging from 0 to \(N - 1\). Under the phantom Bethe roots criterion (PRC) (5), the inhomogeneous BAE can reduce to homogeneous ones with \(M\) or \(M = N - 1 - M\) preserved finite Bethe roots \([5–7, 9]\) and the Hilbert space splits into two invariant subspaces \(G^+\) and \(G^-\), whose dimensions are determined by the integer \(M\) \([14, 15]\). The PRC also serve as the compatibility condition of the modified ABA method \([5, 18]\).

Under the constraint (5), the hermiticity of Hamiltonian (1) requires in the case \(|\Delta| < 1\) (the easy plane regime)
\[
\text{Re}[\alpha_\pm] = \text{Re}[\beta_\pm] = \text{Re}[\eta] = 0, \\
\text{Im}[\beta_\pm] = 0 \text{ and } \beta_+ = -\beta_-, \tag{6}
\]
and in the case \(|\Delta| > 1\) (the easy axis regime)
\[
\text{Im}[\alpha_\pm] = \text{Im}[\beta_\pm] = \text{Im}[\eta] = 0, \\
\text{Re}[\theta_\pm] = 0 \text{ and } \theta_+ = \theta_- \mod 2\pi i. \tag{7}
\]

In the following we show that the two sets of homogeneous BAE correspond to two invariant subspaces \(G^+_M\) and \(G^-_M\) respectively, and their solutions constitute the complete set of eigenstates and eigenvalues under the criterion (5). In addition, we construct explicit phantom Bethe vectors via a chiral coordinate Bethe ansatz, see below.

**ADDITON OF EXTRA AUXILIARY VECTORS TO THE BASES OF \(G^+_M\).**

Here we explain a perhaps most important and subtle feature of the chiral coordinate Bethe ansatz for open systems with non-diagonal boundary fields, satisfying the phantom roots criterion. Namely, we have two invariant subspaces, \(G^+_M\) and \(G^-_M\), and the eigenvectors of \(H\) for each subspace will be given by separate CCBA. Furthermore, the Bethe eigenvectors will be given not as a linear combination of independent original basis vectors, but as a linear combination of the original basis vectors plus other extra auxiliary vectors, which are linearly dependent and are added for convenience. Adding the extra vectors allows to symmetrize the basis and to make the CCBA coefficients elegant and simple. Below we remind of the definition of the basis vectors and show how the extra auxiliary vectors are constructed.

Define the following local left vectors on each site \(n\)
\[
\phi_n(x) = (1, -e^{\theta_- + \alpha_- + \beta_- + (2x - n + 1) \eta} \equiv (1, e^{z_{n,x}}) \tag{8}
\]
\[
z_{n,x} = \theta_- + \alpha_- + \beta_- + (2x - n + 1) \eta + i \pi. \tag{9}
\]
Here the second component of these states depends on the position index \(n\) and \(z_{n,x}\) serves as a phase factor of the state \(\phi_n(x)\). Let us introduce a set of factorized states
\[
(0, \ldots, 0, n_1, \ldots, n_k, N, \ldots, N)_{m_0} \otimes \otimes_{l_1=1}^{n_1} \phi_{l_1}(m_0) \otimes \otimes_{l_2=n_1+1}^{n_2} \phi_{l_2}(m_0 + 1) \otimes \otimes_{l_{k+1}=n_k+1}^{N} \phi_{l_{k+1}}(m_0 + k), \tag{10}
\]
\[0 < n_1 < n_2 < \cdots < n_k < N, \quad k \geq 0.\]

The structure of the states (10) is particular and is very different from the usual computational basis of up and down spins, used for instance to describe the Bethe eigenstates of a periodic XXZ spin chain. The number \(m_0\) defines the initial phase of the first qubit, and the phases of the subsequent qubits increment by an amount \(\eta\) from site to site except at the points \(n_1, \ldots, n_k\), where kinks occur. The states (10) are conveniently graphically represented in a form of trajectories, see Fig. 1. The nature of any state even in the presence of kinks is chiral. The full set of Bethe vectors (all eigenstates of the Hamiltonian) will be expressed by a chiral set (10) as explained below.

It was proved in \([14]\) that the bra vectors (10) with
\[
m_0 + k + m_N = M, \\
m_0 = 0, 1, \ldots, M, \quad m_N = 0, 1, \tag{11}
\]
are all independent and form a basis of the invariant subspace \(G^+_M\), with the dimension \(\dim G^+_M = d(M) = \sum_{n=0}^{[M]} \binom{N}{n} \).
The Hamiltonian $H$ has $d_+(M)$ left eigenvectors which are linear combinations of the $G_M^+$ basis states. The $G_M^+$ basis (11) consists of factorized states with 0 kink, 1 kink, etc. ... up to $M$ kinks, see Fig. 1, Upper Panel.

For our purpose it is convenient to enlarge the basis by adding to (11) extra chiral states of the form (10) with

$$m_0 + k + m_N = M,$$
$$m_0 = 0,1,\ldots M,\ m_N = 2,\ldots M,$$  \hspace{1cm} (12)

rendering the enlarged set of states

$$m_0, m_N = 0,1,\ldots M,\ m_0 + k + m_N = M,$$  \hspace{1cm} (13)

completely symmetric, see Fig. 1, Lower panel. For $M = 0$ and $M = 1$, the basis vector set (11) coincides with the enlarged set (13). For $M > 1$ the number of auxiliary vectors increases monotonically with $M$. For $M = 2,3,4$, the number of auxiliary vectors is $1, N+1, \frac{N^2+N+4}{2}$ respectively. For arbitrary $M \geq 2$, the number of additional vectors can be calculated on combinatorial grounds and is equal to

$$d_+^{M=2}(M) = \sum_{j=0}^{M-2} \sum_{k=0}^{j} \left( N - 1 \right) \left( k \right),$$  \hspace{1cm} (14)

It can be proved (see Appendix B) that all auxiliary vectors are linear combinations of the $d_+(M)$ basis vectors. The full generating set (13) contains in total

$$d_+^{total}(M) = \sum_{j=0}^{M} \sum_{k=0}^{j} \left( N - 1 \right) \left( k \right)$$  \hspace{1cm} (15)

vectors. Each vector from the set corresponds to a directed path in Fig. 1, Lower Panel.

Note that in the $G_M^+$ case, we deal with the bra vectors. In the following we show how to construct the auxiliary vectors for the ket $G_M^+$ basis.

**Adding auxiliary ket vectors to the basis of $G_M^+$**

Analogously, introduce the local ket states,

$$\tilde{\phi}_n(x) = \left( e^{-\theta_- - \alpha - \beta_+ + (2x-n+1)\eta} \right),$$  \hspace{1cm} (16)

and construct factorized states out of them

$$\langle 0,\ldots,0,m_1,\ldots,m_k,N,\ldots,N \rangle \rangle,$$

obtainable from bra vectors (10) via the replacement $\phi \rightarrow \tilde{\phi}$. Analogously to (11), the above ket states with

$$m_0 + k + m_N = \tilde{M},$$
$$m_0 = 0,1,\ldots \tilde{M},\ m_N = 0,1,$$  \hspace{1cm} (17)

where $\tilde{M} = N-1-M$, form a basis of the invariant subspace $G_M^-$ [14]. Adding additional ket states in analogy to (12), we get another fully symmetric set of ket vectors with

$$m_0, m_N = 0,1,\ldots \tilde{M},\ m_0 + k + m_N = \tilde{M},$$  \hspace{1cm} (18)

and their total number is

$$d_-^{total}(M) = \sum_{j=0}^{\tilde{M}} \sum_{k=0}^{j} \left( N - 1 \right) \left( k \right).$$  \hspace{1cm} (19)
PHANTOM BETHE EIGENSTATES IN $G_M^+$ FOR $M = 0, 1, 2$

$M = 0$ case

When $M = 0$, the invariant subspace $G_M^+$ consists of just one state, a spin-helix state (SHE) [19–21]

$$
\langle \Psi_0 | = \phi_1(0) \cdots \phi_N(0),
$$

(20)

with

$$
\langle \Psi_0 | H = \langle \Psi_0 | E_0, \\
E_0 = -\sinh(\eta) (\coth(\alpha_-) + \tanh(\beta_-)) \\
+ \coth(\alpha_+) + \tanh(\beta_+)),
$$

(22)

see [14, 15]. In the factorized state $\langle \Psi_0 |$, the qubit phase grows linearly, implying underlying chiral properties of the state. Indeed, for a Hermitian Hamiltonian in the easy plane regime, the SHE $\langle \Psi_0 |$ for $\beta_\pm = 0$ carries the magnetic current

$$
j^z = \frac{\langle \Psi_0 | j^z_1 | \Psi_0 \rangle}{\langle \Psi_0 | \Psi_0 \rangle} = 2 \sin \gamma,
$$

(23)

$$
\hat{j}^z_k = 2(\sigma^x_k \sigma^x_{k+1} - \sigma^y_k \sigma^y_{k+1}).
$$

For a Hermitian system in the easy axis regime (7), the SHE $\langle \Psi_0 |$ carries no magnetic current, i.e. $j^z = 0$. Remarkably, the SHE (20) has been produced experimentally in a system of cold atoms where the $z$-axis anisotropy of the Heisenberg interaction can be controlled by Feshbach resonance [22, 23].

$M = 1$ case

Define the following factorized states

$$
| n \rangle = e^{i \eta} \phi_1(0) \cdots \phi_n(0) \phi_{n+1}(1) \cdots \phi_N(1).
$$

(24)

The states $| 0 \rangle, | 1 \rangle, \ldots, | N \rangle$ span the subspace $G_M^+$ [14]. Consequently there exist $N+1$ Bethe eigenstates which are linear combinations of the basis vectors

$$
\langle \Psi_1^\alpha | = \sum_{n=0}^{N} | n \rangle f_n^\alpha, \quad \alpha = 0, 1, \ldots, N,
$$

(25)

where the greek upper index $\alpha$ enumerates the states of the $G_M^+$ multiplet.

Define the boundary parameters

$$
a_\pm = \frac{\sinh(\alpha_\pm + \eta)}{\sinh(\alpha_\pm)}, \\
b_\pm = \frac{\cosh(\beta_\pm + \eta)}{\cosh(\beta_\pm)}.
$$

(26)

The coefficients $\{f_n^\alpha\}$ can be written in the following coordinate Bethe ansatz form [14]

$$
f_n^\alpha = g_n \left( A_+^\alpha e^{i p n} + A_-^\alpha e^{-i p n} \right), \quad 0 \leq n \leq N,
$$

$$
g_0 = \frac{1}{1 - a_- b_-}, \\
g_N = \frac{1}{1 - a_+ b_+}, \\
g_1 = g_2 = \cdots = g_{N-1} = 1.
$$

(27)

Note that writing $f_n^\alpha$ as a product of the listed $g_n$ times a second factor allows this one to be a sum of plane waves for all sites $n$ even at the ends with $n = 0$ and $N$. The quasi-momentum $p(\alpha)$ is subject to Eq. (31) which is the consistency condition for the following relations for the amplitudes $A_\pm^\alpha$

$$
A_\alpha^\alpha = S_L(p(\alpha)) A_+^\alpha, \\
A_\alpha^n = e^{2iNp(\alpha)} S_R(p(\alpha)) A_+^\alpha,
$$

(28)

where $S_L(p)$ and $S_R(p)$ are the reflection matrices on left and right boundaries [24] respectively with

$$
S_L(p) = \frac{1 - a_- e^{i p}}{a_- - e^{i p}} \frac{1 - b_- e^{i p}}{b_- - e^{i p}},
$$

(29)

$$
S_R(p) = \frac{1 - a_+ e^{i p}}{a_+ - e^{i p}} \frac{1 - b_+ e^{i p}}{b_+ - e^{i p}}.
$$

(30)

The compatibility condition of Eq. (28) is exactly the BAE for $M = 1$

$$
e^{2iNp(\alpha)} \prod_{\sigma = \pm} a_\sigma - e^{i p} b_\sigma - e^{i p} = 1.
$$

(31)

The solutions of BAE (31) are denoted by $p(\alpha)$ with $\alpha = 0, \ldots, N$. The corresponding eigenvalue in terms of the Bethe root $p(\alpha)$ is given by

$$
E(\alpha) = 4 \cos(p(\alpha)) - 4 \Delta + E_0.
$$

(32)

For a Hermitian system, the single quasi-momentum $p(\alpha)$ can be real or purely imaginary. It has been proved in [14] that the invariant subspaces $G_M^+$ have additional internal structure when at least one of the additional constraints $a_\pm b_\pm = 1$ is satisfied.

Once the eigenstates are constructed, physical quantities can be calculated, e.g. the expectation value of the spin current. A qualitative analysis yields that the spin currents in the single particle multiplet can differ from the SHE current $j^z_{HS} = 2 \sin \gamma$ at most by $O \left( \frac{1}{N} \right)$ corrections in the easy plane regime. Consider a Hermitian Hamiltonian in the easy plane regime with the boundary parameters

$$
\beta_+ = \beta_- = 0, \quad \alpha_\pm = -i \gamma \pm i \frac{\pi}{2} \mod 2 \pi i,
$$

$$
\theta_- - \theta_+ = i(N - 1) \gamma \mod 2 \pi i.
$$

(33)

The explicit expressions of the current in the $N+1$ eigenstates are [14]

$$
j^z(\alpha) = \frac{\langle \Psi_1^\alpha \mid j^z \mid \Psi_1^\alpha \rangle}{\langle \Psi_1^\alpha \mid \Psi_1^\alpha \rangle}
$$

$$
= 2 \sin \gamma \left( 1 - \frac{4}{N} \frac{1 - \cos^2(p(\alpha))}{1 + \Delta^2 - 2 \Delta \cos(p(\alpha))} \right),
$$

(34)

$$
p(\alpha) = \frac{\pi \alpha}{N}, \quad \alpha = 0, \ldots, N.
It can be seen from the above that all phantom Bethe states are current carrying states: the upper and lower bounds for the current of the multiplet are of order of the SHS current $j_{SHS}$,

$$j_{SHS} \left( 1 - \frac{4}{N} \right) \leq j^\gamma (\alpha) \leq j_{SHS} = 2 \sin \gamma. \quad (35)$$

The upper bound is saturated; indeed $j^\gamma (0) = j^\gamma (N) = j_{SHS}$ since the respective Bethe states $\langle \Psi_1^{(\alpha)} \rangle$ with $\alpha = 0, N$ are in fact spin helix states, differing by an initial phase. The lower bound is approached most closely for $p(\alpha) \leq \gamma \leq p(\alpha + 1)$, and it can be saturated if an $\alpha$ satisfies $p(\alpha) = \gamma$, i.e. for some root of unity anisotropies.

In the following we omit the upper index $\alpha$ enumerating the physical BAE solutions for brevity of notation.

$$M = 2 \text{ case}$$

For $M = 2$, we follow the same procedure to construct the Bethe eigenstates, via a generating set (13), i.e. vectors $\langle 0, 0 \rangle, \langle 0, 1 \rangle, \ldots, \langle 0, N \rangle, \ldots, \langle N, N \rangle$.

Using convenient notations

$$w_\pm = a_\pm + b_\pm, \quad (36)$$

the action of $H$ on the set $\langle n, m \rangle$ is given by

$$\langle 0, 0 \rangle | H = (4\Delta a_- b_- - w_- - w_+) \langle 0, 0 \rangle | + 4\Delta (w_- - 2\Delta a_- b_-) \langle 0, 1 \rangle |, \quad (37)$$

$$\langle 0, 1 \rangle | H = (w_- - w_+ - 4\Delta a_- b_-) \langle 0, 1 \rangle | + 2 \langle 0, 2 \rangle | + 2 a_- b_- | 0, 0 \rangle |, \quad (38)$$

$$\langle 0, n \rangle | H = (w_- - w_+ - 4\Delta) \langle 0, n \rangle | + 2 \langle 0, n-1 \rangle | + 2 \langle 0, n+1 \rangle | + 2 \langle 1 - a_- b_- \rangle \langle 1, n \rangle |, \quad 2 \leq n \leq N-1, \quad (39)$$

$$\langle 0, N \rangle | H = (w_+ - w_- - 4\Delta) \langle 0, N \rangle | + 2 \langle 1 - a_- b_- \rangle \langle 1, N \rangle | + 2 \langle 1 - a_+ b_+ \rangle \langle 0, N-1 \rangle |, \quad (40)$$

$$\langle n, m \rangle | H = - (w_- + w_+ + 4\Delta) \langle n, m \rangle | + 2 \langle n-1, m \rangle | + 2 \langle n+1, m \rangle |$$

$$+ 2 \langle n, m+1 \rangle | + 2 \langle n, m-1 \rangle |, \quad 1 \leq n < m \leq N-1, \quad m-n > 1, \quad (41)$$

$$\langle n, n+1 \rangle | H = - (w_- + w_+ \langle n, n+1 \rangle | + 2 \langle n-1, n+1 \rangle | + 2 \langle n, n+2 \rangle |, \quad 1 \leq n \leq N-2, \quad (42)$$

$$\langle n, N \rangle | H = (w_+ - w_- - 4\Delta) \langle n, N \rangle | + 2 \langle n-1, N \rangle | + 2 \langle n+1, N \rangle | + 2 \langle 1 - a_+ b_+ \rangle \langle n, N-1 \rangle |, \quad 1 \leq n \leq N-2, \quad (43)$$

$$\langle N-1, N \rangle | H = (w_+ - w_- - 4\Delta a_+ b_+) \langle N-1, N \rangle | + 2 \langle N-2, N \rangle | + 2 a_+ b_+ \langle N, N \rangle |, \quad (44)$$

$$\langle N, N \rangle | H = (4\Delta a_+ b_+ - w_+ - w_-) \langle N, N \rangle | + 4\Delta (w_+ - 2\Delta a_+ b_+) \langle N-1, N \rangle |. \quad (45)$$

Obviously, the factorized states $\langle n, m \rangle$ span an invariant subspace $G_2^\pm$ of $H$. The respective phantom Bethe eigenstates belonging to $G_2^\pm$ can be written as a linear combination of $\langle n, m \rangle$ as

$$\langle \Psi_2 \rangle = \sum_{0 \leq n_1 < n_2 \leq N} \langle n_1, n_2 \rangle | f_{n_1, n_2} + \sum_{n=0, N} \langle n, n \rangle | f_{n, n}, \quad (46)$$

with yet unknown eigenvalue $E$. Later, for convenience, we extend the notation to a double sum over $0 \leq n_1 \leq n_2 \leq N$ with, however, $f_{n, n} \equiv 0$ for $n \neq 0, N$.

We write $E$ as

$$E = 2\Delta - 8\Delta + E_0, \quad (47)$$

where $E_0$ is defined in Eq. (22). The eigenvalue equation $\langle \Psi_2 \rangle | H = \langle \Psi_2 \rangle | E$ gives rise to the following recursive identities for the coefficients $f_{n, m}$.
We propose the following ansatz
\[
 f_{n,m} = g_{n,m} \sum_{\sigma_1, \sigma_2 = \pm} \left( A_{\sigma_1, \sigma_2}^{1,2} e^{i\sigma_1 n p_1 + i\sigma_2 m p_2} + A_{\sigma_2, \sigma_1}^{2,1} e^{i\sigma_2 n p_2 + i\sigma_1 m p_1} \right),
\]
where \( p_1, p_2 \) are quasi-momenta and the coefficients \( \{g_{n,m}\} \) are \( p \)-independent. We impose \( g_{n,m} \equiv 1 \) for \( n, m \neq 0, N \). Considering the bulk term Eq. (48) with \( m \neq n + 1 \) and using the ansatz (61), we get the expression of \( \Lambda \) and energy
\[
 \Lambda = 2 \cos(p_1) + 2 \cos(p_2),
\]
\[
 E = 4 \sum_{j=1}^{2} \cos(p_j) - 8 \Delta + E_0.
\]
To satisfy Eq. (48) with \( m = n + 1 \), we get the two-body scattering matrix [24]
\[
 A_{\sigma_2, \sigma_1}^{2,1} = S_{1,2}(\sigma_1 p_1, \sigma_2 p_2) A_{\sigma_1, \sigma_2}^{1,2},
\]
where \( S \) has the following symmetry and explicit form
\[
 S_{1,2}(p, p') = S_{2,1}(-p', -p)
 = -\frac{1 - 2\Delta e^{ip} + e^{ip' + ip}}{1 - 2\Delta e^{ip} + e^{ip' + ip}}.
\]
The ansatz (61) allows us to get the following expressions from Eqs. (49) and (50)
\[
 g_{n,N} = \frac{1}{1 - a_+ b_+}, \quad g_{0,n} = \frac{1}{1 - a_- b_-},
\]
\[
 2 \leq n \leq N - 2.
\]
The boundary dependent Eqs. (52) and (53) determine the following left and right reflection matrices respectively
\[
 A_{\sigma_1, \sigma_2}^{j,k} = S_L(p_j) A_{\sigma_1, \sigma_2}^{j,k},
\]
\[
 A_{\sigma_1, \sigma_2}^{j,k} = e^{2iNp_k} S_R(p_k) A_{\sigma_1, \sigma_2}^{j,k},
\]
\[
 (\Lambda - 2\Delta \delta_{n+1,m}) f_{n,m} = f_{n+1,m} + f_{n-1,m} + f_{n,m+1} + f_{n,m-1}, \quad 2 \leq n < m \leq N - 2,
\]
\[
 (\Lambda - 2\Delta \delta_{n,N-2}) f_{n,N-1} = f_{n+1,N-1} + f_{n-1,N-1} + f_{n,N-2} + (1 - a_+ b_+) f_{n,N}, \quad 2 \leq n \leq N - 2,
\]
\[
 (\Lambda - 2\Delta \delta_{m,n}) f_{m,n} = f_{m+1,n} + f_{m-1,n} + f_{m,n+1} + f_{m,n-1}, \quad 2 \leq m \leq N - 2,
\]
\[
 \Lambda f_{1,N-1} = f_{2,N-1} + f_{1,N-2} + (1 - a_+ b_+) f_{1,N} + (1 - a_- b_-) f_{0,N-1},
\]
\[
 (\Lambda - w_-) f_{0,m} = f_{0,m+1} + f_{0,m-1} + f_{m,1} - 2 \Delta f_{0,1}, \quad 2 \leq m \leq N - 2.
\]
where the reflection matrices \( S_L(p) \) and \( S_R(p) \) are given by Eqs. (29)-(30).
\[
 S_L(p) = -\frac{1 - a_- e^{ip}}{a_- - e^{ip}} \frac{1 - b_- e^{ip}}{b_- - e^{ip}},
\]
\[
 S_R(p) = -\frac{a_+ - e^{ip}}{1 - a_+ e^{ip}} \frac{b_+ - e^{ip}}{1 - b_+ e^{ip}}.
\]
The scattering matrix in (65) and reflection matrices in (29), (30) determine all the amplitudes \( A_{\sigma_1, \sigma_2}^{j,k} \). The consistency condition of our ansatz gives the BAE
\[
 e^{2iNp_j} S_{j,k}(p_j, p_k) S_R(p_j) S_k(l_j, p_k, -l_j)
 \times S_L(-l_j) = 1, \quad j, k = 1, 2, \quad j \neq k.
\]
One can verify that our BAE in (71) is consistent with the one given by the modified ABA [5] and the functional \( T-Q \) relation [6, 9], see Appendix A. Letting \( m \) in (52) and \( n \) in (53) take values 2 and \( N - 2 \) respectively and using the reflection matrices (29), (30), we have
\[
 g_{1,N} = g_{N-1,N} = \frac{1}{1 - a_+ b_+},
\]
\[
 g_{0,1} = g_{0,N-1} = \frac{1}{1 - a_- b_-},
\]
\[
 extending the result (66) to \( 1 \leq n \leq N - 1 \). Substituting the result in (72) into Eq. (54), we get the expression of \( g_{0,N} \)
\[
 g_{0,N} = \frac{1}{(1 - a_- b_-)(1 - a_+ b_+)}.
\]
The remaining coefficients \( f_{0,0} \) and \( f_{N,N} \) are derived from
Eqs. (57) and (58)

\[ g_{0,0} = \frac{a_b}{2\Delta(1-a_b)(w_- - 2\Delta a_-)} \]

\[ g_{N,N} = \frac{a_b}{2\Delta(1+a_+)(w_+ - 2\Delta a_+)} \]

Using Eqs. (113)-(115), we reparameterize the functions \( g_{n,m} \) in terms of \( \alpha_\pm \) and \( \beta_\pm \) as

\[ g_{n,m} = \begin{cases} 
1, & n, m \neq 0, N, \\
F_-(1), & n = 0, m \neq 0, N, \\
F_+(1), & n \neq 0, m = N, \\
F_-(1)F_+(1), & n = 0, m = N, \\
F_-(1)F_-(2), & n = m = 0, \\
F_+(1)F_+(2), & n = m = N, 
\end{cases} \]

where

\[ F_\sigma(k) = \delta_{k,0} - (1 - \delta_{k,0}) \frac{\sinh(\alpha_\sigma + (k-1)\eta)}{\sinh(\eta k)}, \]

\[ \times \cosh(\beta_\sigma + (k-1)\eta) \frac{\sinh(\alpha_\sigma + \beta_\sigma + k\eta)}{\sinh(\eta k)}, \sigma = \pm. \]

Note that for our further generalization (79) it is convenient to define \( F_\sigma(0) = 1 \) via (76), even though \( F_\sigma(0) \) does not appear in (75). One can prove that our ansatz (61), (75) satisfies all the relations (48)-(60), see Appendix D.

Remark. In the generic case, the invariant subspace \( G_2^+ \) is irreducible. However, on special manifolds, further internal structures appear, leading to the existence of one or more subspaces, which are invariant w.r.t. the action of the Hamiltonian. As an example, for \( a_+b_+ = 1 \), three invariant subspaces of \( G_2^+ \) appear. The details of this further structuring and the consequences for the BAE sets are discussed in Appendix E.

**GENERALIZATION FOR ARBITRARY \( M \)**

On the basis of our findings we formulate the following hypothesis: phantom Bethe vectors, i.e. Bethe states with infinite rapidities resp. momenta \( k_j = \pm \gamma_j \), are for general \( M \) given by a superposition of the states (10). We denote the vector \( \langle 0, \ldots, 0, \tilde{n}_1, \ldots, \tilde{n}_k, N, \ldots, N \rangle \) from (10) simply as \( \langle n_1, \ldots, n_M \rangle \), where some of the first site labels \( n_j \) may be identical to 0 and some of the last labels identical to \( N \).

We have seen in the \( M = 1,2 \) cases, that writing \( f_n \) or \( f_{n,m} \) as a product of certain prefactors \( g_n \) or \( g_{n,m} \) times a second factor allows this one to be a sum of plane waves for all sites even at the ends with \( n \) or \( m \) equal to 0 or \( N \). Analysing the \( M = 1,2 \) cases, we see that the prefactors \( g \) only depend on the number of site labels 0 resp. \( N \). This inspired us to formulate a general rule for the arbitrary \( M \) case with a certain prefactor \( g_{n_1,\ldots,n_M} = C_{m_0,m_N} \) where \( m_0 \) and \( m_N \) denote the number of site labels equal to 0 resp. \( N \) in the sequence \( n_1, \ldots, n_M \). Using this rule we find

\[ \langle \Psi_M \rangle = \sum_{n_1,\ldots,n_M} \langle n_1, \ldots, n_M | f_{n_1,\ldots,n_M} \rangle 
\]

\[ f_{n_1,\ldots,n_M} = C_{m_0,m_N} \sum_{r_1,\ldots,r_M} \sum_{\delta_1,\ldots,\delta_M = \pm} A_{\sigma_1,\ldots,\sigma_M}^{r_1,\ldots,r_M} \]

\[ \times e^{i \sum_{k=1}^{M} \sigma_k n_k p_{r_k}}, \]

where in (77) we sum over all configurations \( n_1, \ldots, n_M \) allowed by (13). The first sum in (78) is over all permutations \( r_1, \ldots, r_M \) of \( 1, \ldots, M \), while the coefficients \( C_{m_0,m_N} \) depend only on \( m_0, m_N \) and are given by remarkably simple expressions

\[ C_{m_0,m_N} = \prod_{k=0}^{m_0} F_-(k) F_+(l) \prod_{l=0}^{m_N} F_+(l). \]

where \( F_{\sigma}(m) \) are defined by Eq. (76). The amplitudes \( A_{\sigma_1,\ldots,\sigma_M}^{r_1,\ldots,r_M} \) are determined by the two-body scattering matrix \( S \) in (65) and the reflection matrices \( S_L, S_R \) in (29)-(30)

\[ A_{\sigma_1,\ldots,\sigma_M}^{r_1,\ldots,r_M} = S_{r_1} S_{r_2} \cdots S_{r_M} (\sigma_1 n_1, \sigma_2 n_2 + 1) \]

\[ \times A_{\sigma_2,\ldots,\sigma_M}^{r_2,\ldots,r_M} \]

\[ A_{\sigma_1,\ldots,\sigma_M}^{r_1,\ldots,r_M} = e^{2iN p_{r_1} + i \pi} S_R(p_{r_1}) A_{\sigma_1,\ldots,\sigma_M}^{r_1,\ldots,r_M} \]

The compatibility of the whole scheme is guaranteed by a set of transcendental equations for the quasi-momenta, the BAE

\[ e^{2iN p_{r_1} + i \pi} S_{r_1} S_{r_2} \cdots S_{r_M} (p_{r_1}, p_{r_2}, \ldots, p_{r_M}) S_R(p_{r_1}) \]

\[ \times A_{\sigma_1,\ldots,\sigma_M}^{r_1,\ldots,r_M} = 1, \quad r_1 = 1, \ldots, M. \]

The BAE (83) coincide with those obtained by other approaches [5, 6]. The corresponding eigenvalue in terms of quasimomenta \( \{ p_1, \ldots, p_M \} \) is

\[ E = 4 \sum_{j=1}^{M} (\cos(p_j) - \Delta) + E_0. \]

Analogously we construct the other set of eigenstates \( \langle \Psi_M \rangle \) belonging to \( G_{-M} \). The substitutions

\[ \alpha_\pm \rightarrow -\alpha_\pm, \quad \beta_\pm \rightarrow -\beta_\pm, \quad \theta_\pm \rightarrow i\pi + \theta_\pm, \]

leave the Hamiltonian invariant and give the following replacements

\[ M \rightarrow \tilde{M}, \quad a_\pm \rightarrow \tilde{a}_\pm, \quad b_\pm \rightarrow \tilde{b}_\pm, \]

where

\[ \tilde{a}_\pm = \frac{\sinh(\alpha_\pm - \eta)}{\sinh(\alpha_\pm)} \quad \tilde{b}_\pm = \frac{\cosh(\beta_\pm - \eta)}{\cosh(\beta_\pm)}. \]
The vectors in (13), (18), and the fundamental relations (102)-(111) all show the symmetry (85) and (86). This is sufficient to prove that the eigenstates \(|\Psi_M\rangle\) can be constructed in analogy to (77). Following (77), we make the ansatz

\[
|\Psi_M\rangle = \sum_{n_1, \ldots, n_M} \tilde{f}_{n_1, \ldots, n_M} |n_1, \ldots, n_M\rangle, \tag{88}
\]

with

\[
\tilde{f}_{n_1, \ldots, n_M} = \tilde{C}_{m_0, m_N} \sum_{r_1, \sigma_{r_1}, \ldots, \sigma_{r_M}} \tilde{A}_{r_1, \sigma_{r_1}, \ldots, \sigma_{r_M}} \times e^{i \sum_{k=1}^{M} \sigma_{r_k} n_k \bar{v}_{r_k}}. \tag{89}
\]

Substituting \(A_{r, \sigma_{r}}, \tilde{C}_{m_0, m_N}\) and \(\{p_1, \ldots, p_M\}\) in Eqs. (79)-(84) with \(\tilde{A}_{r, \sigma_{r}}, \tilde{C}_{m_0, m_N}\) and \(\{\tilde{p}_1, \ldots, \tilde{p}_M\}\) respectively and then using the substitutions (85), (86), we get another chiral coordinate Bethe ansatz, now for the \(G_M^\perp\) Bethe eigenvectors.

The chiral coordinate Bethe ansatz in Eqs. (77)-(83) and (88)-(89) are the main result of this paper. Eqs. (77)-(83) give the full set of Bethe vectors for the \(G_M^\perp\) invariant subspace and the dual Eqs. (88)-(89) give the full set of Bethe vectors for the \(G_M^\perp\) invariant subspace, in total, all \(2^N\) phantom Bethe vectors.

At present, it is difficult to prove our hypotheses in (78) and (89) completely. However, there are many arguments that corroborate our hypotheses. On one hand, we retrieve the same BAE which have been obtained by other approaches. On the other hand, the correctness of our conjecture for at least a part of the coefficients \(f_{n_1, \ldots, n_M}\) in (78) can be proved for arbitrary \(M\).

**SPIN HELIX EIGENSTATES**

Among the vectors constituting the \(G_M^\perp\) basis plus the auxiliary vectors, there are \(M + 1\) linearly independent spin helix states (SHS) of the form

\[
\langle \text{SHS}; m| = \bigotimes_{n=1}^N \phi_n(m) \propto \left(0, \ldots, 0, N, \ldots, N\right), \tag{90}
\]

\(m = 0, \ldots, M\),

which have the same chirality but different initial qubit phase.

Below we look for conditions under which these SHS become eigenstates of the Hamiltonian. Acting by the Hamiltonian \(H\) on these SHS and using Eqs. (102)-(105), we find

\[
\langle \text{SHS}; m|H| \text{SHS}; m\rangle = - \left(\frac{\sinh \eta \cosh(\alpha_- + \beta_- + 2m\eta)}{\sinh(\alpha_-) \cosh(\beta_-)} + \frac{\sinh \eta \cosh(\alpha_+ + \beta_+ + 2(M-m)\eta)}{\sinh(\alpha_+) \cosh(\beta_+)} \right) \langle \text{SHS}; m| \tag{91}
\]

where \(m\) is an arbitrary integer, and the integer \(M\) has the range \(0 \leq M \leq N - 1\). For a Hamiltonian under the PRC (5), the crossing parameter \(\eta\) can only take \(N - 2M - 1\) discrete values with relative positions equidistant in the complex plane [9]. Under this condition, the Hilbert space splits into two invariant subspaces [14] and remarkable singular peaks in the magnetization current of the associated dissipative quantum system occur [25], which can now be related to the existence of spin helix eigenstates and their generalizations in the spectrum of the effective Hamiltonian.

Under the PRC, two conventional BAE with \(M = \tilde{M} = N - M - 1\) regular Bethe roots appear, which correspond to two invariant subspaces \(G_M^\perp\) and \(G_{\tilde{M}}^\perp\), with the dimensions

\[
\dim G_M^\perp = \sum_{k=0}^{M} \binom{N}{k} \quad \text{and} \quad \dim G_{\tilde{M}}^\perp = \sum_{k=M+1}^{N} \binom{N}{k} = 2^{N} - \dim G_M^\perp.
\]

Our proposed chiral coordinate Bethe ansatz allows to construct the full set of Bethe eigenstates, separately for \(G_M^\perp\) and \(G_{\tilde{M}}^\perp\), as a linear combination over a symmetric set of vec-

**DISCUSSION**

We have analyzed the integrable open XXZ spin-\(\frac{1}{2}\) chain satisfying the phantom Bethe roots existence Criterion (PRC),

\[
\eta = \frac{\alpha_- + \beta_- + \alpha_+ + \beta_+ + \theta_- - \theta_+ + 2m\eta}{N - 2M - 1}, \tag{92}
\]

It is clear from the above that the SHS \(\langle \text{SHS}; m|\) becomes an eigenstate of \(H\) if one or two additional conditions are satisfied, namely:

(i) when \(\cosh(\alpha_- + \beta_- + M\eta) = 0\), \(\langle \text{SHS}; M|\) is an eigenstate of \(H\),

(ii) when \(\cosh(\alpha_+ + \beta_+ + M\eta) = 0\), \(\langle \text{SHS}; 0|\) is an eigenstate of \(H\),

(iii) when \(\cosh(\alpha_+ + \beta_+ + (M-m)\eta) = 0\), \(\cosh(\alpha_- + \beta_- + m\eta) = 0\), \(m \neq 0, M\), \(\langle \text{SHS}; m|\) is an eigenstate of \(H\),

and the corresponding eigenvalues are given by Eq. (91).
tors, spanning the respective chiral invariant subspace. The set of vectors contains spin helix states with “kinks”. Unlike in the periodic case, we have to treat the non-diagonal boundary fields which break the magnetization conservation, i.e. the $U(1)$ symmetry. The integer $M$ determines the maximum number of “kinks”. An exciting result is that the expansion coefficients for the open spin chain, in the chiral basis of SHS with kinks, have a very simple analytic form.

We demonstrated that for small $M$, the Bethe eigenstates have some unusual chiral properties such as high magnetization currents.

Our method can be generalized to other integrable open systems, not necessarily of quantum origin, such as the asymmetric simple exclusion process (ASEP) with open boundaries [26, 27], the spin-1 Fateev-Zamolodchikov model [28] and spin-$s$ integrable systems [29]. Potentially, a generalization of our results to the XYZ spin-$\frac{s}{2}$ chain [30] might exist, which is a challenging open problem.

The formulation of the chiral coordinate Bethe ansatz has become possible due to the existence of phantom Bethe roots, which appear both in open and periodically closed systems [15].

Another interesting question is how to obtain the eigenstates of non-Hermitian systems under PRC. Using our bases and the chiral coordinate Bethe ansatz method, we can always construct the left or right eigenstates which correspond to one subspace, whether the system is Hermitian or not. For a Hermitian system the dual states can be directly obtained. If the system is not Hermitian, the construction of the dual states is still challenging. A very intuitive example is the one-species ASEP with open boundary conditions, which belongs to the $M = 0$ case. The left steady state of the Markov matrix is a simple factorized state, while the right steady state has a very complicated structure, which however can be calculated exactly by other approaches, the matrix product approach [31] or the recursive approach [32].

Our results may lay the basis for further analytic studies and may possibly serve for a new understanding relevant for experimental applications, e.g. the experimental realization of the model and eigenstates by techniques presented in [22, 23].

**Appendix A: BAE resulting from modified ABA**

It has been proved under condition (5) there exists a conventional BAE [5, 6, 9],

$$
\left[ \frac{\sinh(x_j + \frac{i}{2})}{\sinh(x_j - \frac{i}{2})} \right]^{2N} \prod_{\sigma = \pm} \sinh(x_j - \alpha_\sigma - \frac{\eta}{2}) \sinh(x_j + \alpha_\sigma + \frac{\eta}{2})
$$

$$
\times \frac{\cosh(x_j - \beta_\sigma - \frac{\eta}{2})}{\cosh(x_j + \beta_\sigma + \frac{\eta}{2})} = \prod_{k \neq j}^{M} \sinh(x_j - x_k + \eta) \sinh(x_j - x_k - \eta)
$$

$$
\times \frac{\sinh(x_j + x_k + \eta)}{\sinh(x_j + x_k - \eta)} , 
\quad j = 1, \ldots, M. \tag{93}
$$

The above BAE, in terms of the single particle quasimomentum $p_j$

$$
e^{ip_j} = \frac{\sinh(x_j + \frac{i}{2})}{\sinh(x_j - \frac{i}{2})}, \tag{94}
$$

take the form [14]

$$
e^{2iNp_j} \prod_{\sigma = \pm} a_\sigma - e^{ip_j} = b_\sigma - e^{ip_j} 1 - a_\sigma e^{ip_j} 1 - b_\sigma e^{ip_j}
$$

$$
= \prod_{\sigma = \pm} \prod_{k \neq j}^{M} \frac{1 - 2\Delta e^{ip_j} + e^{ip_j + i\sigma p_k}}{1 - 2\Delta e^{ip_j + i\sigma p_k}}, \quad j = 1, \ldots, M, \tag{95}
$$

where $a_\pm$, $b_\pm$ are defined in (26). Valid physical Bethe roots \{$p_1, \ldots, p_M$\} satisfy the selection rules $e^{ip_j} \neq e^{ip_k}$, $e^{ip_j} \neq \pm 1$. We see that Eq. (95) is identical to our BAE (83) in the main text. The invariance of the Hamiltonian $H$ w.r.t. the substitution (85) under condition (5) allows to construct another set of homogeneous BAE by replacing $a_\pm$, $b_\pm$ and $M$ in (95) with $-a_\pm$, $-b_\pm$ and $\tilde{M} = N - 1 - M$ respectively, see [14]. The second set of BAE thus reads

$$
e^{2iN\tilde{p}_j} \prod_{\sigma = \pm} \tilde{a}_\sigma - e^{i\tilde{p}_j} = \tilde{b}_\sigma - e^{i\tilde{p}_j} 1 - \tilde{a}_\sigma e^{i\tilde{p}_j} 1 - \tilde{b}_\sigma e^{i\tilde{p}_j}
$$

$$
= \prod_{\sigma = \pm} \prod_{k \neq j}^{\tilde{M}} \frac{1 - 2\Delta e^{i\tilde{p}_j} + e^{i\tilde{p}_j + i\sigma \tilde{p}_k}}{1 - 2\Delta e^{i\tilde{p}_j + i\sigma \tilde{p}_k}}, \quad j = 1, \ldots, \tilde{M}, \tag{96}
$$

where $\tilde{a}_\pm$, $\tilde{b}_\pm$ are defined in Eq. (87).

**Appendix B: Linear dependence of the auxiliary vectors**

Here we show that all extra auxiliary bra vectors participating in the CCBA, are linear combinations of the basis vectors of $G_M^+$, and similarly, all extra auxiliary ket vectors are linear combinations of the $G_M^-$ basis vectors. For the proof, it is enough to demonstrate that any bra vector from the extended (symmetrized) bra set is orthogonal to any ket vector from the extended (symmetrized) ket set, i.e. (101).
To this end, define the function $y(n, v_n, \tilde{v}_n)$ as
\begin{align}
\phi_n(v_n)\phi_{\tilde{n}}(\tilde{v}_n) &= 1 - e^{2\nu(n, v_n, \tilde{v}_n)\eta}, \\
y(n, v_n, \tilde{v}_n) &= v_n + \tilde{v}_n - n + 1. 
\end{align}
(97)

When $y(n, v_n, \tilde{v}_n) = 0$, the local vectors $\phi_n(v_n)$ and $\tilde{\phi}_n(\tilde{v}_n)$ are orthogonal. Introduce the inner products
\begin{align}
\langle n_1, \ldots, n_M | m_1, \ldots, m_{-M} \rangle &= e^{\eta \sum_{j=1}^M n_j + \eta \sum_{k=1}^M m_k} \prod_{n=1}^N \left(1 - e^{2\nu(n, v_n, \tilde{v}_n)\eta}\right), \tag{98}
\end{align}
where $\langle n_1, \ldots, n_M |$ belongs to the extended $G^+_M$ set of vectors and $| m_1, \ldots, m_{-M} \rangle$ belongs to the extended $G^+_M$ set of vectors. Obviously,
\begin{align}
0 &\leq v_1 \leq v_2 \leq \ldots \leq v_N \leq M, \\
0 &\leq \tilde{v}_1 \leq \tilde{v}_2 \leq \ldots \leq \tilde{v}_N \leq \tilde{M}, \\
v_{n+1} - v_n &= 0,1, \quad \tilde{v}_{n+1} - \tilde{v}_n = 0,1. 
\end{align}
(99)

Appendix C: The proof of Eqs. (37)-(45)

It is easy to prove the following identities:
\begin{align}
\phi_n(x)\phi_{n+1}(x)h_{n,n+1} &= \sinh\nu \phi_n(x)\phi_{n+1}(x)\sigma_n^\pm - \sinh\nu \phi_n(x)\phi_{n+1}(x)\sigma_{n+1}^\pm, \tag{102}
\phi_n(x)\phi_{n-1}(x)h_{n,n-1} &= \sinh\nu \phi_n(x)\phi_{n-1}(x)\sigma_n^\pm - \sinh\nu \phi_n(x-1)\phi_{n+1}(x)\sigma_{n}^\pm, \tag{103}
\phi_1(x)h_1 &= \frac{\sinh\nu}{\sinh(\nu)\cosh(\nu)} \left(\cosh(\nu)\sinh(\nu) - \sinh(\nu + \nu + 2\nu)\right) \phi_1(x)\sigma_1^\pm, \tag{104}
\phi_N(x)h_N &= \frac{\sinh\nu}{\sinh(\nu)\cosh(\nu)} \left(\cosh(\nu + \nu + 2(\nu)\eta) - \cosh(\nu)\sinh(\nu)\right) \phi_N(x)\sigma_N^\pm, \tag{105}
\phi_{n,n+1}\phi_{n+1}(x)\phi_{n+1}(x)h_{n,n+1} &= \sinh\nu \sigma_n^\pm \phi_n(x)\phi_{n+1}(x) - \sinh\nu \sigma_{n+1}^\pm \phi_n(x)\phi_{n+1}(x), \tag{106}
\phi_{n,n+1}\phi_{n+1}(x)\phi_{n+1}(x)h_{n,n+1} &= \sinh\nu \sigma_{n+1}^\pm \phi_{n+1}(x) - \sinh\nu \sigma_{n+1}^\pm \phi_{n+1}(x), \tag{107}
\phi_1(x)h_1 &= \frac{\sinh\nu}{\sinh(\nu)\cosh(\nu)} \left(\cosh(\nu)\sinh(\nu) - \sinh(\nu + \nu - 2\nu)\right) \phi_1(x)\sigma_1^\pm, \tag{108}
\phi_N(x)h_N &= \frac{\sinh\nu}{\sinh(\nu)\cosh(\nu)} \left(\cosh(\nu + \nu - 2(\nu)\eta) - \cosh(\nu)\sinh(\nu)\right) \phi_N(x)\sigma_N^\pm. \tag{109}
\end{align}

We note the useful identities
\begin{align}
\phi_n(x)\sigma_n^\pm &= \pm \frac{\cosh\nu}{\sinh\nu} \phi_n(x) \mp \frac{\sinh\nu}{\sinh\nu} \phi_n(x) \pm, \tag{110}
\sigma_n^\pm \phi_n(x) &= \pm \frac{\cosh\nu}{\sinh\nu} \phi_n(x) \pm \frac{\sinh\nu}{\sinh\nu} \phi_n(x) \pm. \tag{111}
\end{align}

Using Eqs. (102)-(105) and (110) repeatedly, we get Eqs. (37)-(45). Some identities, used in our calculations, are:
\begin{align}
E_0 &= -w_- - w_+ + 4\Delta, \tag{112}
\sinh\nu \cosh(\nu + \nu + 2\nu) &= w_- - 2\Delta. \tag{113}
\end{align}
\[
\frac{\sinh \eta \cosh (\alpha_{\pm} + \beta_{\pm} + \eta)}{\sinh (\alpha_{\pm} \cosh (\beta_{\pm}))} = a_{\pm} b_{\pm} - 1, \quad (114)
\]
\[
\frac{\sinh \eta \cosh (\alpha_{\pm} + \beta_{\pm} + 2\eta)}{\sinh (\alpha_{\pm} \cosh (\beta_{\pm}))} = 2a_{\pm} b_{\pm} \Delta - w_{\pm}. \quad (115)
\]

**Appendix D: The proof of Eqs. (48)-(60)**

Define the auxiliary function
\[
W_{n,m} = \sum_{\sigma_1, \sigma_2 = \pm} (A_{1,2}^{1,2} e^{i \sigma_1 n_1 + i \sigma_2 n_2} + A_{2,1}^{2,1} e^{i \sigma_2 n_2 + i \sigma_1 n_1}),
\]
where \( n, m \) are arbitrary integers. Using BAE (71), the scattering matrix in (65) and reflection matrices in (29), (30), one can get the following properties of \( W_{n,m} \)
\[
\Lambda W_{n,m} = \sum_{\sigma = \pm 1} (W_{n+\sigma,m} + W_{n,m+\sigma}), \quad (117)
\]
\[
2\Delta W_{n+1,n+1} = W_{n+1,n+1} + W_{n,n}, \quad (118)
\]
\[
w_{-} W_{0,n} = a_{-} b_{-} W_{1,n} + W_{-1,n}, \quad (119)
\]
\[
w_{+} W_{n,N} = a_{+} b_{+} W_{n,N-1} + W_{n,N+1}, \quad (120)
\]
\[
(\Lambda - 2\Delta a_{-} b_{-} - 2\Delta) W_{0,0} = 2\Delta (w_{-} - 2\Delta a_{-} b_{-}) W_{0,1}, \quad (121)
\]
\[
(\Lambda - 2\Delta a_{+} b_{+} - 2\Delta) W_{N,N} = 2\Delta (w_{+} - 2\Delta a_{+} b_{+}) W_{N-1,N}. \quad (122)
\]

With the help of Eqs. (117)-(122), we can prove that our ansatz satisfies all the relations (48)-(60). For instance, Eq. (55) can be proved as follows
\[
(\Lambda - w_{-} - w_{+}) f_{0,N}
= g_{0,N} (\Lambda - w_{-} - w_{+}) W_{0,N}
= g_{0,N} [(1 - a_{-} b_{-}) W_{1,N} + (1 - a_{+} b_{+}) W_{0,N-1}]
= f_{1,N} + f_{0,N-1}. \quad (123)
\]

**Appendix E: Possibility of a further partitioning of the invariant subspaces on special manifolds**

Let us consider the special case: \( a_{\pm} b_{\pm} = 1 \). Under this specific condition, from Eq. (40) the SHS \( \{ 0, N \} \) is an eigenstate of \( H \)
\[
\langle 0, N | H = (w_{-} + w_{+} - 4\Delta) | 0, N \rangle. \quad (124)
\]

This SHS \( \{ 0, N \} \) corresponds to a special limiting case solution of BAE (71) with \( p_1 = -i \ln (a_{-}), \quad p_2 = -i \ln (a_{+}) \). In fact, both numerator and denominator on the left hand side of (71) become zero, but the ratio stays finite.

The bra vectors \( \langle 0, n |_n = 0, \ldots , N \) form another sub-subspace as follows
\[
\langle 0, 0 | H = (4\Delta - w_{-} - w_{+}) \langle 0, 0 | + 4\Delta (w_{-} - 2\Delta) \langle 0, 1 |,
\]
\[
\langle 0, n | H = (w_{-} - w_{+} - 4\Delta) \langle 0, n | + 2 \langle 0, n - 1 | + 2 \langle 0, n + 1 |, \quad 1 \leq n \leq N - 1,
\]
\[
\langle 0, N | H = (w_{-} + w_{+} - 4\Delta) \langle 0, N |. \quad (125)
\]

The phantom Bethe states belonging to the above invariant sub-subspace have the form \( \langle \Psi_2 | = \sum_{n=0}^{N} | 0, n | f_{0,n} \rangle \). Guided by Eq. (125) we propose \( f_{0,n} \) to be a sum of plain waves.
\[
f_{0,n} = A_{+} e^{ip} + A_{-} e^{-ip}, \quad n = 1, \ldots , N - 1, \quad (126)
\]
while \( f_{0,0}, f_{0,N} \) will be derived from the consistency conditions of (125). Following Eqs. (125) and (126) we obtain
\[
f_{0,0} = \frac{A_{+} + A_{-}}{2\Delta (w_{-} - 2\Delta)}, \quad f_{0,N} = \frac{f_{0,N-1}}{2 \cos (p) - w_{+}}, \quad (127)
\]
and
\[
\frac{A_{-}}{A_{+}} = - \prod_{u=a_{-},b_{-}} \frac{1 - 2\Delta e^{ip} + u e^{ip}}{1 - 2\Delta u + u e^{ip}} = -e^{2iNp}. \quad (128)
\]

The corresponding energy reads \( E = 4 \cos (p) + w_{-} - w_{+} - 4\Delta \) where \( p \) satisfies the reduced BAE
\[
e^{2iNp} = \prod_{u=a_{-},b_{-}} \frac{1 - 2\Delta e^{ip} + u e^{ip}}{1 - 2\Delta u + u e^{ip}}. \quad (129)
\]

We can also get the same BAE (129) by letting \( p_1, p_2 \) in the BAE (71) be \(-i \ln (a_{-})\) and \( p \) respectively (note that for the Hermitian case the constants \( a_{\pm}, b_{\pm} \) are real). Noticing that \( \pm p \) are equivalent solutions and excluding two trivial solutions \( p = 0, \pi \), BAE (129) has \( N \) independent non-trivial solutions.

Analogously, the bra vectors \( \langle n, N |, n = 0, \ldots , N \) form another sub-subspace. Suppose that \( \langle \Psi_2 | = \sum_{n=0}^{N} | n, N | f_{n,N} \rangle \). The coefficients \( f_{n,N} \) can be obtained via the following transformation
\[
f_{n,N} \rightarrow f_{0,N-n}, \quad \text{with} \quad a_{\pm}, b_{\pm}, w_{\pm} \rightarrow a_{\mp}, b_{\mp}, w_{\mp}.
\]

The corresponding energy is \( E = 4 \cos (p) + w_{+} - w_{-} - 4\Delta \) where the quasi-momentum \( p \) is a solution of the following BAE
\[
e^{2iNp} = \prod_{u=a_{\mp},b_{\mp}} \frac{1 - 2\Delta e^{ip} + u e^{ip}}{1 - 2\Delta u + u e^{ip}}. \quad (130)
\]

The remaining \( \binom{N}{2} - N \) eigenstates span the full \( G_{2}^{+} \) basis. The two reflection matrices in (29) and (30) become \(-1\) and \(-e^{2iNp_0} \) respectively. In this case, the “boundary terms” in Eq. (71) vanish and the BAE (71) acquire a simple form
\[
e^{2iNp_j} = \prod_{\sigma = \pm} \prod_{k \neq j} \frac{1 - 2\Delta e^{ip_j} + e^{ip_j} + i e^{ip_k}}{1 - 2\Delta e^{ip_j} + e^{ip_j} + i e^{ip_k}}, \quad j = 1, 2. \quad (131)
\]
To sum up, in the special case we consider, the set of Bethe root pairs \( \{ p_1, p_2 \} \) in the original BAE (71) splits into 4 subsets:

(i) one pair \( \{ p_1, p_2 \} = \{-i \ln(a_+), -i \ln(a_-)\} \) corresponding to \( \text{SHS} (0, N) \),
(ii) \( N \) pairs \( \{ p_1, p \} \) with \( p_1 = -i \ln(a_-) \) and \( p \) given by the solution of (129),
(iii) \( N \) pairs \( \{ p_1, p \} \) with \( p_1 = -i \ln(a_+) \) and \( p \) given by the solution of (130),
(iv) \( \binom{N}{2} - N \) pairs \( \{ p_1, p_2 \} \) given by the solution of BAE (131).

In total, there are \( 1 + N + \binom{N}{2} \) \( G_2^+ \) solutions, as expected.

Our example shows that there can be further partitionings of \( G_2^+ \), which for \( a_+ b_+ = 1 \) leads to three internal invariant subspaces of dimension 1, \( N/N \) within \( G_2^+ \) which are invariant w.r.t. the action of \( H \). Likewise, if just one of the two conditions \( a_+ b_\pm = 1 \) is satisfied, some internal invariant subspaces disappear, while others remain. Under other constraints (arising when the coefficients of some “unwanted” terms on the RHS of Eqs. (37)-(45) vanish) various internal invariant subspaces of \( G_2^+ \) can appear.
