Abstract: This paper intends to use data to verify the correlation between safety culture, safety management system and safety knowledge, safety awareness, and safety habits, which is the correlation between the various parts of the behavior safety “2-4” model. Due to data limitations, the results are limited to the study of safety culture related relationships in coal mining enterprises. This paper first designed a questionnaire containing 30 questions, of which 1–5 questions represent safety culture, 6–22 questions represent safety management system, and 23–30 questions represent safety knowledge, safety awareness and safety habits. Employees of 27 coal mining enterprises in Shandong, Henan, Hunan and other places in China were surveyed and sampled by stratified random sampling, and 1514 valid questionnaires were obtained. After item analysis and correlation analysis, and it was found that, within the data of 1514 questionnaires, the item total correlation coefficients of questions 6, 9, 19 and 28 were all less than 0.2, indicating that the identification degree of these four items was poor, which was deleted. Using the data analysis of the remaining 26 questions in the questionnaire, it was found that the relationship between safety culture and the safety management system, the safety management system and safety knowledge, and safety awareness and safety habits is moderately related; safety culture and safety knowledge, safety awareness and safety habits are weakly related. The conclusion shows that the safety culture directly affects the safety management system; the safety management system directly affects the safety knowledge, safety awareness and safety habits; the safety culture indirectly affects safety knowledge, safety awareness and safety habits. However, why the expected strong correlation is not achieved, and whether the same conclusion can be obtained if the data scale is expanded or other types of enterprises are added for questionnaire measurement, these are questions worthy of further study, which is also the author’s next research content.

Keywords: safety culture; safety management; safety knowledge; safety awareness; safety habits

1. Introduction

Professor Fu in the project team where the author works put forward the behavior safety “2-4” model [1], as shown in Figure 1 below. The project team members used the model to analyze 748 coal mine accidents. For details, see the website information in Ref. [2] and several published papers. The paper deals with coal mine accident analysis [3] and accidents in other industries [1,4–8]. The behavior safety “2-4” model points out that safety culture directly affects the safety management system, the safety management system directly affects the safety knowledge, safety awareness and safety habits; the safety culture indirectly affects safety knowledge, safety awareness and safety habits. However, why the expected strong correlation is not achieved, and whether the same conclusion can be obtained if the data scale is expanded or other types of enterprises are added for questionnaire measurement, these are questions worthy of further study, which is also the author’s next research content.
the correlation between the safety culture, safety management system, safety knowledge, safety awareness and safety habits that caused the accident has not been studied. Therefore, this paper intends to use the questionnaire design method to obtain data to verify the correlation between safety culture, safety management system and safety knowledge, safety awareness and safety habits.

Ref. [9] analyzes the research status of China’s safety culture, and introduces the development, achievements and prospects of China’s safety culture, in which the author and the member of the project team (Gui Fu, Wei Jiang) are mentioned. This article is also a continuation of the safety culture research content of the author and author’s research team.

At present, scholars have studied the relationship between safety culture and safety management, safety culture and safety performance, safety culture and other related content. These studies are both qualitative and quantitative.

Regarding the relationship between safety culture and safety management, many scholars have found that safety culture has a direct or indirect impact on safety management. For example, Guldenmund [10] analyzed the safety culture of the core, performance and overall dimensions. It is concluded that, through the combination of these three safety cultures, the concept of safety culture can be reshaped and the analytical potential of safety culture in understanding the development and implementation of safety management systems can be enhanced. Robertson [11] conducted a safety culture survey using the university aviation program and found a relationship between safety management implementation and safety culture, safety improvement and safety culture, management commitment and safety culture. Hendershot [12] found that an effective process safety culture is very important to achieve effective process safety management, and a good safety culture is the key to excellent process safety management. Lin et al. [13] found that the intensity of safety culture has a direct or indirect impact on the safety management system and can affect the safety performance of the company. Rollenhagen and Wahlström’s [14] research shows that the safety of nuclear power plants cannot always be based on prescribed instructions. The management system and safety culture should solve this problem, and should better understand the structure and content of the management system and their impact on the safety of nuclear power plants. McDonald et al. [15] studied various aspects of the safety management system and safety culture of the four organizations and found that the
safety management systems and safety culture of the four organizations are largely consistent. There is no difference between the four organizations’ adherence to mission procedures and safety attitudes, but with different subcultures, indicating differences in the concept of safety culture. Grote [16] studied the uncertainty in management and proposed that safety culture is one of the means. It is suggested that the different roles and importance of safety culture depend on the selected uncertainty management method. It is required that any safety culture assessment must be evaluated through the matching between the uncertainty faced by the organization and the uncertainty forms selected to deal with. Gao et al. [17] established a model to explore the mediating role of safety management practices in the development of process safety culture. Four safety management practices, including organizing responsibilities/procedures, communication and coordination, safety training, and inspection and monitoring, have been found to have positive mediating effects on safety culture, with inspection and monitoring presenting the highest mediating effect.

For the research on safety culture and behavior, Fung et al. [18] investigated the relationship between people’s safety culture and behavior, attitude and cognition, and made a comparison. The research showed that organizational commitment has a high correlation with communication, supervisors, individuals, workers, risk-taking behavior and other aspects. Tylor [19] studied the safety culture model associated with the organization’s shared safety awareness to observable safety behavior, and used accident cases to study the relationship between safety culture and observable safety behavior. Ismail et al. [20] evaluated the impact of environmental behavior factors on the development of safety culture and found that the internal environment of the organization is weak and will affect safety behavior. In addition, through interviews with senior management, it was discovered that the company’s safety culture status was contributed by the established system. The Naevestada et al. [21] study found that safety cultures at different analytical levels influence different types of unsafe behaviors, which in turn influence the risk of work injuries. It is recommended to study the impact of culture on traffic safety at different levels of analysis (i.e., countries, departments, and organizations).

Regarding safety culture and safety performance research, Kalteh et al. [22] uses the keywords “Safety Culture and Safety Performance” and “Safety and Performance” to select English articles published in 2005–2017 from different databases, and evaluates the role of safety culture in safety performance in 31 articles extracted. It is found that improving the safety culture level can effectively reduce accidents and improve safety performance indicators. Feng et al. [23] uses a variety of techniques to collect data from 47 completed construction projects in Singapore. Research shows that the safety performance of construction projects depends on the synergies between safety investment, safety culture and engineering hazards. Chen et al. [24] explored the interactive relationship between Taiwan’s construction industry safety culture and corporate safety performance, and found that safety culture has certain predictive power and influence on Taiwan’s construction industry safety performance.

There are also related studies on the relationship between safety culture or safety management system and knowledge. For example, Vinodkumar et al. [25] used a questionnaire survey to measure employees’ cognition of six safety management practices and self-reported safety knowledge, safety motivation, safety compliance and safety participation. It turns out that safety knowledge and safety motivation are key factors in interpreting these relationships. Firoozi et al. [26] found that knowledge is an important source of capital for an organization and can only be correctly created and managed in a healthy cultural environment. The paper adopts a health, safety, environment and cultural model as a management model, which enables people to have a deep understanding of the health and safety culture that promotes the interaction and transformation process. Azer et al. [27] explored the relationship between organizational culture, knowledge management, and patient safety performance. The study found that different dimensions of organizational culture are associated with more effective knowledge management, and knowledge management is associated with better patient safety performance. Warszawska et al. [28] identified six aspects of safety culture through safety
culture assessments: knowledge and skills, awareness, information flow, monitoring and supervision, management commitment, and continuous improvement. Kuimet et al. [29] studied the links and developments between human resource management, organizational safety culture and knowledge management literature, which found that the concept and framework of human resource management can play an important role in the communication of safety knowledge within the organization.

This paper intends to use data to verify the relevance between safety culture, safety management system and safety knowledge, safety awareness, and safety habits.

2. Description of Research Methods and Content

This paper intends to use the questionnaire design method to obtain data to verify the correlation between safety culture, safety management system and safety knowledge, safety awareness and safety habits, as shown in Figure 2 below.

![Figure 2. Correlation between safety culture, safety management and safety knowledge, safety awareness, safety habits.](image)

The research method is to analyze the contents of safety culture, safety management, safety knowledge, safety awareness and safety habits in the literature [1], design multiple questions for each part of the content, form a questionnaire, and use the SPSS software (SPSS Inc., Chicago, IL, USA) to analyze the data obtained from the questionnaire. Finally, the correlation results of safety culture, safety management, safety knowledge, safety awareness and safety habits are obtained.

The definitions and contents of safety knowledge, safety awareness, safety habits, safety management system and safety culture are shown in literature [30]. It should be explained that this article does not attempt to separate safety knowledge, safety awareness and safety habits, but to use them as a concept to verify its relevance to safety culture and safety management. The reason is that, in the behavior safety “2-4” model, insufficient safety knowledge, poor safety awareness and poor safety habits are all indirect causes of accidents.

3. The Questionnaire Design

For the meaning of each part of safety culture, safety management system, safety knowledge, safety awareness, and safety habits, set up multiple questions, form a questionnaire, and outline the content of each question, as shown in Table 1 below.

| Category       | Questionnaire Subject Number | Summarization of Questionnaire Subject Content                                      |
|----------------|------------------------------|--------------------------------------------------------------------------------------|
| Safety culture | 1                            | The importance of safety                                                              |
|                | 2                            | The degree to which casualties can be prevented                                       |
|                | 3                            | Safety creates economic benefits                                                      |
|                | 4                            | The degree of safety integration into corporate management                             |
|                | 5                            | Safety is mainly determined by safety awareness                                       |

Table 1. Overview of questionnaire setting contents.
Table 1. Cont.

| Category | Questionnaire Subject Number | Summarization of Questionnaire Subject Content |
|----------|------------------------------|-----------------------------------------------|
| Safety management system | 6 | Awareness of safety inputs |
| | 7 | The role of safety regulations |

| | 30 | Emergency capability |

4. The Selection and Basic Situation of the Investigated Personnel

Since the distribution, filling and collection of the questionnaire will affect the daily work of the enterprise, and the questionnaire needs to be filled out voluntarily by the enterprise. After the inquiry, 27 coal mine enterprises are willing to assist in filling out the questionnaire. These 27 coal mine enterprises are located in Shandong, Henan, Hunan and other places in China. In each enterprise, stratified random sampling was used to sample a total of 1610 employees were selected, and 1610 questionnaires were issued. Excluding the questionnaires with too much reaction tendency and missed questions, 1514 valid questionnaires were obtained, and the effective recovery rate was 94%.

This section counts three parameters of the basic situation of the tested personnel: personnel structure, education level and working years.

4.1. Personnel Structure

The investigated personnel were mainly divided into four categories: (1) Management, that is, cadres at the middle level or above; (2) Foreman, that is, the leader who directly leads the front-line staff or “leads the team”, usually the squad leader, the team leader, etc.; (3) professional, called non-leading cadres in China, are characterized by higher consciousness and higher education level compared with front-line staff, and can generally complete a certain task independently; and (4) front-line staff, that is, those who directly perform on-site operations. The stratified random sampling method was used to extract testers. According to the proportion of each type of personnel, 249 management personnel, 332 professionals, 376 foremen, and 557 front-line staff, totaling 1,514 people, were selected, as shown in Figure 3.
This section counts three parameters of the basic situation of the tested personnel: personnel structure, education level and working years.

4.1. Personnel Structure

The investigated personnel were mainly divided into four categories: (1) Management, that is, cadres at the middle level or above; (2) Foreman, that is, the leader who directly leads the front-line staff or “leads the team”, usually the squad leader, the team leader, etc.; (3) Professional, called non-leading cadres in China, are characterized by higher consciousness and higher education level compared with front-line staff, and can generally complete a certain task independently; and (4) front-line staff, that is, those who directly perform on-site operations. The stratified random sampling method was used to extract testers. According to the proportion of each type of personnel, 249 management personnel, 332 professionals, 376 foremen, and 557 front-line staff, totaling 1,514 people, were selected, as shown in Figure 3.

4.2. Educational Level

Figure 4 describes the degree of education of employees in the coal mine enterprise under investigation. Among the “overall personnel”, high school education and above account for a relatively high proportion, reaching 77.5%, indicating that the overall level of cultural quality of the tested personnel is relatively high. Among them, the number with junior college education is the largest, accounting for 424 people, and accounting for 28% of the total sample. The lowest number of people with an education level below junior high school was 51, accounting for 3.4% of the total sample. The education level of the management and professionals is mostly junior college or above, accounting for 85.1% and 88.2%, indicating that the cultural quality of the management and technical personnel in the tested coal mines is relatively high.

4.3. Working Years

Figure 5 describes the working years of coal mine employees in the coal mine enterprise under investigation. The proportion of employees with “10 years of work experience” in “management, foremen, professionals, front-line staff” was 60.2%, 57.8%, 51.6%, and 62.7%, respectively; the proportion of “all personnel” was 58.5%. These people have accumulated a lot of technical and management experience in the long-term work. In work practice and training, these employees can tell more about their personal experience and lessons, which is helpful for enterprise safety work and other related work, and can reduce the accident rate of enterprise safety production.
4.3. Working Years

Figure 5 describes the working years of coal mine employees in the coal mine enterprise under investigation. The proportion of employees with “10 years of work experience” in “management, foremen, professionals, front-line staff” was 60.2%, 57.8%, 51.6%, and 62.7%, respectively; the proportion of “all personnel” was 58.5%. These people have accumulated a lot of technical and management experience in the long-term work. In work practice and training, these employees can tell more about their personal experience and lessons, which is helpful for enterprise safety work and other related work, and can reduce the accident rate of enterprise safety production.

![Proportion of Working Years](image)

**Figure 5.** Basic situation of the working years of the tested employees.

5. Questionnaire Measurement Results Item Analysis

The item analysis mainly analyzes the discrimination degree of the questionnaire items, and identifies whether the questionnaire items can clearly distinguish the degree of reaction of different test subjects. Item analysis is conducted for each safety culture level questionnaire item, and those items that are not discriminating or not highly discriminating are the items of the measurement questionnaire that need to be deleted.

5.1. Critical Ratio Method

The item analysis of the questionnaire uses the critical ratio method. Firstly, reverse scoring was performed on the reverse questions in the measurement items, and the total scores of all tested personnel on the measurement scale were calculated; the upper and lower 27% are the grouping criteria, and the first 27% of the total measurement score is set as high grouping, and the last 27% of the total measurement score is set as low grouping; Using the Independent sample t-test, the significant difference between the average scores of the high and low groups on each measurement item is tested. If the result of the t-test reaches a significant level, it indicates that the measurement item can identify the response of different test subjects, that is, the item has a high degree of discrimination. If the result of the t-test does not reach the significance level, or the t-statistic of the difference between the high and low group of the item is less than 3, it means that the degree of discrimination of the item is poor, and it may be considered to delete it. In this paper, reverse scoring is carried out for the reverse items in the measurement items, and the total score of all items is calculated, and the ranking is conducted.
according to the score. SPSS software was used to conduct the Independent sample \( t \)-test, and the mean significance difference between the low group and the high group on 32 items was obtained. The test results are shown in Table A1.

From the results of the Independent sample \( t \)-test in Table A1, the \( t \)-statistic values of the differences between high and low groups of the 30 items in the questionnaire are all greater than 3, and the significance level of the \( t \)-test is 0.000, indicating that the 30-measurement item has a high degree of discrimination and can identify the responses of different test groups.

5.2. Correlation Method

The correlation method is to calculate the correlation between the scores of each item and the total score of all items, that is, the total correlation coefficient of the items. The items with a total correlation coefficient less than 0.20 should be eliminated; the item with a total correlation coefficient between 0.20 and 0.29 can be barely used; the items with a total correlation coefficient between 0.30 and 0.39 are good and will be retained; the items with a total correlation coefficient greater than 0.40 are excellent and will be retained [31]. This paper calculates the correlation coefficient between the scores of 30 questions in the questionnaire and the total score. The results are shown in Table 2.

| Question | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   | 10  |
|----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Correlation coefficient | 0.338 | 0.451 | 0.364 | 0.309 | 0.327 | 0.196 | 0.446 | 0.326 | 0.185 | 0.470 |
| Question | 11  | 12  | 13  | 14  | 15  | 16  | 17  | 18  | 19  | 20  |
| Correlation coefficient | 0.285 | 0.338 | 0.363 | 0.378 | 0.404 | 0.326 | 0.383 | 0.269 | 0.153 | 0.367 |
| Question | 21  | 22  | 23  | 24  | 25  | 26  | 27  | 28  | 29  | 30  |
| Correlation coefficient | 0.322 | 0.452 | 0.336 | 0.330 | 0.329 | 0.289 | 0.261 | 0.097 | 0.300 | 0.350 |

It can be seen from Table 2 that the total correlation coefficient of the item in questions 6, 9, 19 and 28 is less than 0.2, indicating that the discrimination of these four items is poor and will be deleted. The total correlation coefficient of other items is between 0.20 and 0.50, and the item identification is better. The data of the remaining 26 questions are used to prove the relationship between safety culture, safety management system, safety knowledge, safety awareness, and safety habits.

6. Correlation Verification between Safety Culture and Safety Management System and Safety Knowledge, Safety Awareness and Safety Habits

By analyzing the data, the sample distribution is not particularly consistent with the normal distribution, and there is no linear relationship between the two. Therefore, Spearman rank correlation coefficient in correlation analysis is selected for analysis, and the value range of the correlation coefficient in the analysis result is between -1 and +1. The larger the absolute value is, the stronger the correlation was, and the symbol indicates the correlation direction. In addition, 0–0.09 is not correlated, 0.1–0.3 is weakly correlated, 0.3–0.5 is moderately correlated, and 0.5–1.0 is strongly correlated [32,33]. Tables 3–5 list the correlation coefficients between the three categories.

This paper studies the correlation between safety culture, safety management and safety knowledge, safety awareness, and safety habits. Since the behavior safety “2-4” model believes that safety culture directly affects safety management, and safety management directly affects safety knowledge, safety awareness, and safety habits, it is expected that safety culture and safety management are related, preferably having a strong correlation. The same is the relationship between safety management system and safety knowledge, safety awareness, and safety habits. However, the results obtained at the end of this paper are found to be moderately related, indicating that the
relevant relationship to be proved in this paper is successful, but further research is needed to prove whether the correlation can achieve strong correlation and what factors affect the correlation. This is the content of the next study. In the behavior safety “2-4” model, the safety culture indirectly affects safety knowledge, safety awareness, and safety habits through safety management system. The expectation is to prove that safety culture is related to safety knowledge, safety awareness and safety habits. The results obtained in this paper prove that the two are correlated and weakly correlated.

Therefore, this paper has succeeded in determining the correlation between safety culture, safety management and safety knowledge, safety awareness and safety habits through the questionnaire survey. The next step is to further study whether the relationship between safety culture and safety management, safety culture and safety knowledge, safety awareness, and safety habits can achieve strong correlation and factors affecting the correlation.

Table 3. Correlation coefficient between safety culture and safety management system.

| Control Variable | Coefficient | Safety Culture | Safety Management System |
|------------------|-------------|----------------|-------------------------|
| Safety culture   | Correlation coefficient 1.000 | 0.429 ** | 0.000 |
|                  | Significant (two-tailed) 0.000 | 1514 | 1514 |
| Safety management system | Correlation coefficient 0.429 ** | 1.000 | 0.000 |
|                  | Significant (two-tailed) 0.000 | 1514 | 1514 |

** When the confidence level (double test) is 0.01, the correlation is significant.

Table 4. Correlation coefficient between safety management system and safety knowledge, safety awareness and safety habits.

| Control Variable | Coefficient | Safety Management System | Safety Knowledge, Safety Awareness, Safety Habits |
|------------------|-------------|-------------------------|-----------------------------------------------|
| Safety management system | Correlation coefficient 1.000 | 0.376 ** | 0.000 |
|                  | Significant (two-tailed) 0.000 | 1514 | 1514 |
| Safety knowledge, safety awareness, safety habits | Correlation coefficient 0.376 ** | 1.000 | 0.000 |
|                  | Significant (two-tailed) 0.000 | 1514 | 1514 |

** When the confidence level (double test) is 0.01, the correlation is significant.

Table 5. Correlation coefficient between safety culture and safety knowledge, safety awareness and safety habits.

| Control Variable | Coefficient | Safety Culture | Safety Knowledge, Safety Awareness, Safety Habits |
|------------------|-------------|----------------|-----------------------------------------------|
| Safety culture   | Correlation coefficient 1.000 | 0.291 ** | 0.000 |
|                  | Significant (two-tailed) 0.000 | 1514 | 1514 |
| Safety knowledge, safety awareness, safety habits | Correlation coefficient 0.291 ** | 1.000 | 0.000 |
|                  | Significant (two-tailed) 0.000 | 1514 | 1514 |

** When the confidence level (double test) is 0.01, the correlation is significant.
7. Conclusions

In summary, the following conclusions are obtained:

(1) This paper designed a questionnaire with 30 questions, among which 1–5 questions represent safety culture, 6–22 questions represent safety management system, and 23–30 questions represent safety knowledge, safety awareness and safety habits.

(2) The questionnaires designed in this paper were used to measure the employees of 27 coal mines in Shandong, Henan, Hunan and other places in China. Sampling was carried out by stratified random sampling, and 1514 valid questionnaires were obtained.

(3) After project analysis and correlation analysis, it was found that the total correlation coefficients of questions 6, 9, 19 and 28 were all less than 0.2, indicating that the identification degree of these four items was poor, which was deleted.

(4) Using the data analysis of the remaining 26 questions in the questionnaire, it was found that the relationship between safety culture and safety management system, safety management system and safety knowledge, safety awareness, and safety habits are moderately related. Safety culture is weakly related to safety knowledge, safety awareness and safety habits through the analysis of the Spearman rank correlation coefficient between safety culture and safety management system and safety knowledge, safety awareness and safety habits. The correlation coefficient between the safety culture and safety management system is 0.429. The correlation coefficient between safety management system and safety knowledge, safety awareness and safety habits is 0.376. The correlation coefficient between safety culture and safety knowledge, safety awareness, and safety habits is 0.291.

(5) The conclusions in this paper can only prove the correlation and cannot prove the causal relationship.
