ABSTRACT: We use radial quantization to compute Chern-Simons partition functions on handlebodies of arbitrary genus. The partition function is given by a particular transition amplitude between two states which are defined on the Riemann surfaces that define the (singular) foliation of the handlebody. The final state is a coherent state while on the initial state the holonomy operator has zero eigenvalue. The latter choice encodes the constraint that the gauge fields must be regular everywhere inside the handlebody. By requiring that the only singularities of the gauge field inside the handlebody must be compatible with Wilson loop insertions, we find that the Wilson loop shifts the holonomy of the initial state. Together with an appropriate choice of normalization, this procedure selects a unique state in the Hilbert space obtained from a Kähler quantization of the theory on the constant-radius Riemann surfaces. Radial quantization allows us to find the partition functions of Abelian Chern-Simons theories for handlebodies of arbitrary genus. For non-Abelian compact gauge groups, we show that our method reproduces the known partition function at genus one.

1 Introduction

Chern-Simons gauge theory connects many different topics in mathematics and physics. On closed manifolds it is a topological theory that can be used to compute knot invariants [1], while on manifolds with boundaries it acquires additional boundary degrees of freedom that connect it to gravity in three dimensions [2–5] and to the theory of the fractional quantum Hall effect [6, 7]. As remarked in [8], one intriguing feature distinguishes Chern-Simons theory from conventional topological field theories, such as topological Yang-Mills theories on Riemann surfaces or four-manifolds: the latter can be interpreted in terms of the cohomology ring of some classical moduli space of connections, while Chern-Simons, in general, cannot. In fact Chern-Simons theory is intrinsically a quantum theory that is best described by a Hilbert space. When the three-manifold on which the theory is defined has special characteristics, the theory simplifies and may become computable. One remarkable example is the case of Seifert manifolds studied in [8]. Another case which could lead to exact computations is that of handlebodies [9]. The latter is interesting for various reasons. One of the most fascinating is that in order to test any conjectured holographic dualities relating pure gravity in three dimensions to a conformal field theory [10] (or an ensemble average thereof [11–13]), one would need to know the partition function of $SL(2, \mathbb{C})$ Chern-Simons theory on a negatively curved manifold, whose boundary is a Riemann surface. Handlebodies are the simplest such manifolds for a fixed genus of the boundary [14].
The reason why one may think that a Chern-Simons theory may be exactly soluble on handlebodies is that these spaces are *almost* factorized as the topological product $[0, R] \times \Sigma$. We say “almost” because the closed Riemann surface $\Sigma$ defining the foliation of the space becomes singular at one of the extrema of the interval $[0, R]$. The simplest example of this foliation is the solid torus handlebody, that is the direct product of a disk $D^2$ and a circle $S^1$. Its singular foliation is $D^2 \times S^1 \approx [0, R] \times T^2$. The $\approx$ sign means that the two-torus leaf $T^2 = S^1 \times S^1$ becomes singular at the end $r = 0$ of the interval $[0, R]$, where one of the two $S^1$ cycles degenerates. By interpreting $r \in [0, R]$ as time, we can quantize the theory and define a Hamiltonian that evolves in $r$. This allows us to rewrite the partition function of the theory as a transition amplitude between some initial state $|i\rangle$ at $r = 0$ and some final state $|f\rangle$ at $r = R$. We will show in this paper that the condition that the initial state is a “shrunken,” degenerate surface imposes a restriction on the initial state that, combined with the constraints descending from gauge invariance and the independence of the scalar product from the complex structure, completely fixes the partition function.

Let us describe now more precisely the procedure that we shall follow and the organization of this paper. We study partition functions of Chern-Simons theory of compact gauge groups on handlebodies using a radial quantization. First, we establish the equivalence between three quantities: Euclidean path integrals with holomorphic boundary condition, transition amplitudes under radial evolution with a coherent state as the final state, and wave functions integrated over the gauge orbit. Second, we map a Wilson loop inserted in a path integral to a “blown-up” operator defined on the Riemann surface, which in the radial quantization acts on a seed wave function and defines an initial state of definite holonomy along the contractible cycles. Together with an appropriate choice of normalization, this procedure singles out a unique vector in the Hilbert space obtained by a canonical quantization of Chern-Simons theory on the Riemann surface. Moreover, we find that requiring that such “blown-up” operator must be gauge-invariant corresponds to selecting a particular class of framings of the original Wilson loop. We are thus able to establish a precise state-operator correspondence associating each vector in the Hilbert space of the canonically quantized Chern-Simons theory on $\Sigma$ to an explicitly computed partition function with insertions of Wilson loops. We first consider the Abelian $U(1)$ gauge group on the solid torus, then on handlebodies of arbitrary genus and finally we study general compact simple groups on the solid torus.

In section 2, we study the $U(1)$ Chern-Simons theory, first on a torus handlebody and then on handlebodies defined by higher-genus Riemann surfaces. In section 3, we move on to consider the case of a general non-Abelian simple compact Lie group on the torus handlebody. Appendices A and B respectively summarize essential facts about the Riemann theta function and quadratic differentials on a Riemann surface.

### 2 The Abelian case

To study Chern-Simons theory with gauge group $U(1)$ on the genus-$g$ handlebody $M$, we define a singular foliation on $M$ as $M = \Sigma \times [0, R]$. The constant-radius leaves are closed Riemann surfaces, $\Sigma$, and the initial surface $\Sigma_0$ at $r = 0$ is degenerate. The final surface
$\Sigma_R$ is at $r = R$. On $\Sigma$ we specify the complex structure by giving the period matrix $\Omega$, for which $\Sigma$ has area $\det \text{Im} \Omega$, and which defines the basis $\{\omega_I | I = 1, \ldots, g\}$ of Abelian differentials and the local complex coordinate $z$ on $\Sigma$. Since we will be considering either Abelian gauge fields at genus $g$ or non-Abelian gauge fields at genus one, the period matrix will suffice to define the complex structure; we will not need to give explicit definitions of either Teichmüller or moduli space coordinates. We also use the notation $\omega_I = \omega_I(z) dz$, and when it can be done unambiguously we keep the index $I$ implicit.

The integration measure on $\Sigma$ is normalized to $d^2x = dz \wedge d\bar{z}/(-2i)$, so that $\int_\Sigma d^2x \omega_I(z) \bar{\omega}_J(\bar{z}) = (\text{Im} \Omega)^{IJ}$.

One of our goals is to establish the equivalence of three different quantities. The first is a path integral, in which on the final surface $\Sigma_R$ we impose a holomorphic boundary condition that fixes the antiholomorphic part $A_{\bar{z}} d\bar{z}$ of the gauge connection $A$, while on the initial surface $\Sigma_0$ we fix the component of $A$ along the contractible cycles. The second is a transition amplitude under radial evolution, from an initial state of definite holonomy along the contractible cycles to a coherent final state. The third is a wave function in a coherent state basis, obtained by integrating over the gauge orbit a seed wave function which is an eigenstate of the holonomy operator along the contractible cycles.

These quantities will be compared to the Chern-Simons partition functions that are identified with the wave functions obtained by a holomorphic quantization on the Riemann surface $\Sigma$ [15–17]. The basis wave functions spanning the gauge-invariant Hilbert space were explicitly given in [16] as

$$Z(A_{\bar{z}}, \mu; \Omega) = e^{+k\pi u(\text{Im} \Omega)^{-1} u/\tilde{F}(\Omega)^{1/2}} e^{+i \frac{i \pi}{6} \int_\Sigma d^2x \partial_\chi \partial_{\bar{z}} \chi \theta \left[ \frac{k}{0} \right]} (k\mu, k\Omega),$$

(2.1)

$$A_{\bar{z}} d\bar{z} = \partial_{\bar{z}} \chi d\bar{z} + i\pi u(\text{Im} \Omega)^{-1} \omega, \quad \mu \in \mathbb{Z}^g_k, \; k/2 \in \mathbb{Z}. \quad (2.2)$$

The complex number $u$ defines the harmonic part of the differential $A_{\bar{z}} d\bar{z}$ while the integer-valued vector $\mu$ labels the independent vectors spanning the basis of the Hilbert space. Moreover, $k$ is the Chern-Simons level, $\chi$ is a periodic function on $\Sigma$, and $\theta[a][b](u, \Omega)$ is the Riemann theta function with characteristics [18], as defined in (A.1). $\tilde{F}(\Omega)^{1/2}$ is the “holomorphic square root” of the scalar Laplace determinant on $\Sigma$ [19],

$$\frac{\det' \Delta}{\text{Im} \det \Omega} = |\tilde{F}(\Omega)|^2 \exp(-S_{\text{ZTL}}).$$

(2.3)

The obstruction to holomorphic factorization [20], $S_{\text{ZTL}}$, is the nonholomorphic part of the Liouville action defined by Zograf and Takhtajan (see [19, 21]). For genus one on the flat metric, $\tilde{F}(\Omega)^{1/2}$ coincides with the Dedekind eta function: $\tilde{F}(\tau)^{1/2} = \eta(\tau)^1$.

### 2.1 The torus case

As a warm-up, we first consider the case where $M$ is the solid three-dimensional torus. On each constant-radius surface $\Sigma = T^2$ (which is a two-torus) the period matrix is the

\[ S_L = S_{\text{ZTL}} - \pi i \tau/6 + \pi i \tau/6. \]
modular parameter \( \tau \equiv \tau_1 + i \tau_2 \) and defines the global holomorphic coordinate \( z \) on the torus. From this, we can define local real coordinates \( x^{1,2} \) by \( z \equiv x^1 + ix^2 \), where \( x^1 \sim x^1 + 1 \) parametrizes the contractible cycle on \( M \). The restriction to \( T^2 \) of a one-form field \( A \), \( (A_1 dx^1 + A_2 dx^2) \), satisfies

\[
\begin{align*}
A_1 &= A_z + A \bar{z} \\
A_2 &= i(A_z - A \bar{z})
\end{align*}
\]

(2.4)

Although these real coordinates are also valid locally on higher-genus Riemann surfaces, for those cases we will use a better description, given in terms of Strebel differentials [22].

In the next subsections, we establish the equivalence between the three quantities mentioned earlier: the partition function given as a path integral, the transition amplitude, and the gauge invariant wave function obtained from an appropriate “seed” wave function.

**The path integral.** We impose a holomorphic final condition, fixing \( A_z d\bar{z}|_{\Sigma_R} = \partial_z \chi d\bar{z} + i \pi u \tau_2^{-1} \bar{z} \), as in (2.2); on the torus, \( \bar{z} = d\bar{z} \). In addition, as initial condition we fix the component of \( A \) along the contractible cycle \( x^1 \) to some \( A_1|_{\Sigma_0} = A_1^{(0)} \). The corresponding Chern-Simons partition function \( Z(A_z|_{\Sigma_R}, A_1^{(0)}; \tau) \) is given by the path integral

\[
Z(A_z|_{\Sigma_R}, A_1^{(0)}; \tau) \equiv C \int_{A_1|_{\Sigma_0} = A_1^{(0)}_{A_1|\Sigma_0}} DA \exp(iCS + IQ),
\]

(2.5)

where

\[
I_{CS} = - \frac{k}{4\pi} \int_M AdA - \frac{i k}{2\pi} \int_{\Sigma_R} d^2x A_z A_{\bar{z}},
\]

\[
I_Q = + \frac{k}{4\pi} \int_{\Sigma_0} d^2x (A_1 A_2 + f_B[A_1]).
\]

(2.6)

In (2.6), the boundary term \( I_Q = (k/4\pi) \int_{\Sigma_0} d^2x (A_1 A_2 + f_B[A_1]) \), with \( f_B[A_1] \) an arbitrary functional of \( A_1 \), is an appropriate choice for fixing \( A_1 \) on the initial surface \( \Sigma_0 \). The normalization constant \( C \) may depend on the complex structure and it can be fixed only by imposing additional conditions on the partition function. The path integral makes the wave function gauge invariant. An explanation about the gauge invariance of \( Z(A_z|_{\Sigma_R}, A_1^{(0)}; \tau) \) is in order. We are considering the gauge group \( U(1) \), not \( \mathbb{R} \). The distinction is that \( U(1) \) includes large gauge transformations defined on the boundary \( \Sigma_R \) of the handlebody \( M \). A large gauge transformation that has a non-trivial winding along a homotopy cycle of \( \Sigma_R \) that is contractible in \( M \) cannot be extended smoothly to \( M \). This implies that the partition function is a sum of terms that are not related by bulk gauge transformations.

Integrating out \( A_r \), the path integral imposes \( F_{12} = 0 \) [17], so we get

\[
Z(A_z|_{\Sigma_R}, A_1^{(0)}; \tau) = C \int_{A_1|\Sigma_0 = A_1^{(0)}} DA_1 DA_2 \delta(F_{12}) \exp\left(-\frac{ik}{2\pi} \int_M d^2x r A_2 \partial_t A_1\right)
\]

\[
\times \exp\left(-\frac{k}{2\pi} \int_{\Sigma_R} d^2x A_z A_{\bar{z}} + \frac{k}{4\pi} \int_{\Sigma_R} d^2x A_{\bar{z}} A_1 - \frac{k}{4\pi} \int_{\Sigma_R} d^2x A_1 A_1\right)
\]

\[
\times \exp\left(+\frac{ik}{4\pi} \int_{\Sigma_0} d^2x f_B[A_1]\right).
\]

(2.7)
The standard procedure is to express \((A_1 dx^1 + A_2 dx^2)\) as a flat connection, resulting in a chiral Wess-Zumino-Witten path integral on the final surface [17].

**The transition amplitude.** We turn now to the coherent state method. The first term in (2.7) (the bulk term) defines the symplectic structure of the theory, implying that \(A_1\) and \(A_2\) are conjugate variables and satisfy upon quantization the equal-radius canonical commutation relation:

\[
[A_1(x), A_2(y)] = -i \left( \frac{2\pi}{k} \right) \delta^{(2)}(x, y) \quad (2.8a)
\]

\[
\Leftrightarrow [A_\bar{z}(x), A_z(y)] = -\frac{\pi}{k} \delta^{(2)}(x, y). \quad (2.8b)
\]

Here \(\delta^{(2)}(x, y)\) denotes the delta function with respect to the \((x^1, x^2)\)-coordinates. Moreover, define the \(A_1\)-eigenstate \(|A_1\rangle\) as a translation from the \(A_1 = 0\) eigenstate \(|0\rangle\) effected by applying the conjugate momentum \(\hat{A}_2\)

\[
|A_1\rangle \equiv C \exp \left( \frac{i k}{2\pi} \int d^2x \hat{A}_2 A_1 \right) |0\rangle. \quad (2.9)
\]

Here too \(C\) is a normalization constant, which we leave arbitrary for the time being. Using (2.9) together with (2.4), we can construct the wave function of the coherent state \(|A_z\rangle\) in the \(|A_1\rangle\)-basis,

\[
\langle A_1|A_z\rangle = C \exp \left( -\frac{k}{2\pi} \int d^2x A_z^2 + \frac{k}{\pi} \int d^2x A_z A_1 - \frac{k}{4\pi} \int d^2x A_1^2 \right), \quad (2.10)
\]

which satisfies the defining properties (with \(A_\bar{z} = A_1^*\))

\[
\hat{A}_z(x) \langle A_1|A_z\rangle = \frac{1}{2} \left( A_1(x) + \frac{2\pi}{k} \frac{\delta}{\delta A_1(x)} \right) \langle A_1|A_z\rangle = A_z(x) \langle A_1|A_z\rangle, \quad (2.11a)
\]

\[
\hat{A}_1(x) \langle A_\bar{z}|A_1\rangle = \left( + \frac{\pi}{k} \frac{\delta}{\delta A_\bar{z}(x)} + A_\bar{z}(x) \right) \langle A_\bar{z}|A_1\rangle = A_1(x) \langle A_\bar{z}|A_1\rangle. \quad (2.11b)
\]

Let us consider the transition amplitude, from an \(A_1\)-eigenstate \(|A_1^{(0)}\rangle\) on the initial surface \(\Sigma_0\), to a coherent state \(|A_R^{(0)}\rangle\) on the final surface \(\Sigma_R\), as we radially evolve the system with the Hamiltonian read off from (2.7):

\[
\langle A_R^R|e^{-iHR}|A_1^{(0)}\rangle
\]

\[
= \int DA_1^R \langle A_R^R|A_1^R\rangle \langle A_1^R|e^{-iHR}|A_1^{(0)}\rangle \quad (2.12)
\]

\[
= C \int DA_1^R \exp \left( -\frac{k}{2\pi} \int_{\Sigma_R} d^2x A_R^2 + \frac{k}{\pi} \int_{\Sigma_R} d^2x A_R A_1^R - \frac{k}{4\pi} \int_{\Sigma_R} d^2x (A_1^R)^2 \right) \quad (2.13)
\]

\[
\times \int_{A_1^{(0)}|\Sigma_R = A_1^R} DA_1 DA_2 \delta(F_{12}) \exp \left( -\frac{ik}{2\pi} \int_M d^2x dr A_2 \partial_r A_1 \right)
\]

\[
= C \int_{A_1^{(0)}|\Sigma_R = A_1^R} DA_1 DA_2 \delta(F_{12}) \exp \left( -\frac{ik}{2\pi} \int_M d^2x dr A_2 \partial_r A_1 \right) \quad (2.14)
\]

\[
\times \exp \left( -\frac{k}{2\pi} \int_{\Sigma_R} d^2x A_\bar{z}^2 + \frac{k}{\pi} \int_{\Sigma_R} d^2x A_\bar{z} A_\bar{z}^R - \frac{k}{4\pi} \int_{\Sigma_R} d^2x (A_\bar{z}^R)^2 \right).
\]
This is identical to the partition function \( \mathcal{Z}(A_\Sigma|\Sigma_R, A_1^{(0)}; \tau) \), with the boundary term \( f_B[A_1] = 0 \), and \( A^{R}_2 = A_1|\Sigma_0 \). In both cases, we have imposed the initial condition \( A_1|\Sigma_0 = A_1^{(0)} \). The equivalence between \( \mathcal{Z}(A_\Sigma|\Sigma_R, A_1^{(0)}; \tau) \) and \( \mathcal{Z}(A_\Sigma|\Sigma_R, A_1^{(0)}; \tau) \) holds for arbitrary genus because it only relies on a local decomposition of the complex coordinate \( z \) into real coordinates that is independent of the topology of the surface \( \Sigma \). From now on, without ambiguity, we drop the superscript \( R \) from \( A^{R}_2 \).

Next, we evaluate eq. (2.14) and find out what it computes for the torus case. We parametrize the \( A_{1,2} \) that solve the constraint \( F_{12} = 0 \) by

\[
\begin{cases}
A_1(r, x^1, x^2) = a_1(r) + 2\pi n + \partial_1\lambda_0(r, x^1, x^2) \\
A_2(r, x^1, x^2) = a_2(r) + \partial_2\lambda_0(r, x^1, x^2),
\end{cases}
\tag{2.15}
\]

where \( \lambda_0(r, x^1, x^2) \) is a periodic function on \( \Sigma \), and the shift in \( A_1 \) by \( 2\pi n \) with \( n \in \mathbb{Z} \) comes from the large gauge transformations that are singular inside the bulk. Note that a shift in \( \lambda_0(r, x^1, x^2) \) by any \( x^1 \)-independent function \( f_2(r, x^2) \) also solves \( F_{12} = 0 \) and leaves the integrand of the path integral invariant, thus the \( x^1 \)-independent modes can be factored out of the path integral and consistently discarded.\(^2\) On the other hand, shifting \( \lambda_0(r, x^1, x^2) \) by some \( f_1(r, x^1) \) changes the boundary action, so these modes cannot be factored out from the path integral. We restrict our initial condition to \( A_1|\Sigma_0 = a_1(0) \) with \( a_1(0) = \text{constant} \); this is a natural choice since the initial surface is in fact degenerate, so \( \lambda_0(r = 0, x^1, x^2) = \lambda_0(r = 0, x^2) \) is independent of \( x^1 \). The integration measure in (2.14) satisfies [17]

\[
DA_1DA_2\delta(F_{12}) = Da_1Da_2D\lambda_0,
\tag{2.16}
\]

i.e. the change of variables (2.15) has unit Jacobian. Here a prime denotes discarding \( x^1 \)-independent functions. Moreover, as in (2.2), \( A_z = \partial_z\chi + i\pi u\tau_2^{-1} \). The amplitude (2.14) becomes

\[
(A_z|e^{-iHR}|a_1(0)) = Ce^{+\frac{k\pi}{2}u\tau_2^{-1}u + \frac{k}{4\pi}\int_{\Sigma_R} d^2x \partial_\chi \partial_\chi}
\times \int D\lambda_0 \exp \left( -\frac{k}{2\pi} \int_{\Sigma_R} d^2x \partial_1\lambda_0 \partial_2\lambda_0 \right) \tag{2.17}
\times \sum_{n \in \mathbb{Z}} \exp \left( +ik\pi u(a_1(0) + 2\pi n) - \frac{k}{4\pi}(a_1(0) + 2\pi n)\tau_2(a_1(0) + 2\pi n) \right)
\]

\[
= e^{+\frac{k\pi}{2u}u\tau_2^{-1}u + \frac{k}{4\pi}\int_{\Sigma_R} d^2x \partial_\chi \partial_\chi \theta \left[ \frac{a_1(0)}{2\pi} \right]} \tag{2.18}
\]

In arriving at (2.17), we integrated out \( a_2(r) \) to obtain an \( r \)-independent \( a_1(r) = a_1 \). Together with the initial condition \( A_1(r = 0) = a_1(0) \), this means \( a_1(R) = a_1(0) \). We also defined \( \tilde{\lambda}_0 \equiv \lambda_0 + \chi \).

The path integral on \( \tilde{\lambda}_0 \) equals \( \det^{-1/2}(2k\pi \partial_\chi \partial_\chi) \). We are still free to choose the constant \( C \). Besides removing ultraviolet divergences in the functional determinant, it can

\(^2\)This can be shown more rigorously using the BRS formalism [23].
be further fixed by requiring that eq. (2.18) be a section of a projectively flat connection on the moduli space of complex structures [15]. This is simply the requirement that the scalar product of the base wave functions (2.18) must be independent of the complex structure. By making this choice we get $1/\hat{F}(\Omega)^2 = 1/\eta(\tau)$.

Let us compare this to the wave functions $Z(A_\phi, \mu; \Omega)$ (2.1) obtained from holomorphic quantization, that span the gauge-invariant Hilbert space. On the genus $g = 1$ torus $\Sigma = T^2$, they are given by

$$Z(A_\phi, \mu; \tau) = \frac{e^{\frac{i \pi}{k} u \tau^2 u^{-1}}}{\eta(\tau)} e^{\frac{i}{2} \pi \int_{x} d^2x \partial_\chi \partial_{\bar{\chi}} \theta \left[ \frac{\mu}{k} \right]} (k u, k \tau),$$

where $A_\phi = \partial_\z \chi + i \pi u \tau_2^{-1}$, and $\mu = 0, 1, \ldots, k - 1$.

As we set $a_1(0)/2\pi = \mu/k$, we see that the wave function $(A_\phi | e^{-i HR} | a_1(0))$, or equivalently the path integral $Z(A_\phi | \Sigma_R, A_1^{(0)}; \tau$) in (2.7) with $f_B[\Sigma_R] = 0$, differs by a $\tau_1$-dependent phase in the theta function from the function $Z(A_\phi, \mu; \tau)$ in (2.19). So, the wave functions $(A_\phi | e^{-i HR} | a_1(0))$ with $a_1(0)/2\pi = \mu/k$, $\mu = 0, 1, \ldots, k - 1$ exhibit a dependence on the complex structure different from that of the basis wave functions (2.19).

We cannot reabsorb this difference into a redefinition of the constant $C$ without giving up one of the objectives of our paper, which is to establish a state-operator correspondence associating each state obtained by applying Wilson loops to the vacuum to the partition function of Chern-Simons on a solid torus containing the same Wilson loop. So, once we normalize the vacuum and the vacuum partition function, we cannot further normalize separately the other partition functions. What we can do is to understand where the discrepancy comes from and try to fix it by appropriately changing the definition of the Wilson loop operator.

To find the meaning of this discrepancy, we consider a different basis on the torus. We define global coordinates $(\phi, t)$ which both have unit period, so that $z = \phi + \tau t, \phi \sim \phi + 1, \tau \sim \tau + 1$ and

$$\begin{cases}
A_\phi = A_z + A_{\bar{z}} \\
A_t = \tau A_z + \bar{\tau} A_{\bar{z}}
\end{cases} \Leftrightarrow \begin{cases}
A_z = (\tau - \bar{\tau})^{-1} (-\bar{\tau} A_\phi + A_t) \\
A_{\bar{z}} = (\tau - \bar{\tau})^{-1} (\bar{\tau} A_\phi - A_t)
\end{cases}.$$  

(2.20)

In particular, $A_\phi = A_1$, but $A_t = \tau_2 A_2 + \tau_1 A_1 \neq A_2$ in general. The conjugate variables $(A_\phi = A_1, \tau_2^{-1} A_t)$ are related to the previous conjugate variables $(A_1, A_2)$ by a canonical transformation which simply shifts $A_2$ by a term linear in $A_1$. The canonical commutation relation is

$$[A_\phi(x), A_t(y)] = -i \tau_2 \left( \frac{2\pi}{k} \right) \delta^{(2)}(x, y)$$

(2.21a)

$$\Leftrightarrow [A_z(x), A_{\bar{z}}(y)] = -\frac{i \pi}{k} \delta^{(2)}(x, y).$$

(2.21b)

Here $\delta^{(2)}(x, y)$ is again the delta function in the $(x^1, x^2)$ coordinates. Similarly to (2.9), we define the $A_\phi$-eigenstate $|A_\phi\rangle$ by translating the $A_\phi = 0$ eigenstate $|0\rangle \equiv |0\rangle$, but this

---

\(^3\)In the genus-1 case $C$ is in fact independent of the complex structure, as can be seen by an explicit computation [23].
time with the operator $\hat{A}_t$,

$$|A_\phi\rangle \equiv C \exp \left( + \frac{ik}{2\pi} \tau_2^{-1} \int d^2 x \hat{A}_t A_\phi \right) |0\rangle \text{ and } |0\rangle \equiv |0\rangle. \quad (2.22)$$

The eigenstates $|A_\phi\rangle$ and $|A_\phi\rangle$ are related by a pure phase,

$$|A_\phi\rangle = \exp \left( + \frac{ik}{4\pi} \tau_1 \tau_2^{-1} \int d^2 x A_\phi^2 \right) |A_\phi\rangle. \quad (2.23)$$

By using (2.20), we see that the wave function of the coherent state $|A_z\rangle$ in the $|A_\phi\rangle$-basis differs from (2.10)

$$\langle A_\phi | A_z \rangle = C \exp\left(-\frac{k}{2\pi} \int_\Sigma d^2 x A_z^2 + \frac{k}{\pi} \int_\Sigma d^2 x A_\phi - \frac{ik}{4\pi} \tau \tau_2^{-1} \int_\Sigma d^2 x A_\phi^2\right). \quad (2.24)$$

Repeating the same calculations as above, one finds that

$$(A_z|e^{-iHR}|a_\phi(0)) = C e^{\frac{k\pi}{2\tau_2} u_\tau^{-1} \tau + \frac{ik}{2\pi} \int_\Sigma R d^2 x \partial_z \chi \partial_\chi} \times \int D\lambda_0 \exp\left(-\frac{k}{2\pi} \int_\Sigma R d^2 x \partial_1 \lambda_0 \partial_2 \lambda_0 \right)$$

$$\times \sum_{n \in \mathbb{Z}} \exp\left(iku(a_\phi(0) + 2\pi n) + \frac{ik}{4\pi} (a_\phi(0) + 2\pi n) \tau (a_\phi(0) + 2\pi n) \right)$$

$$= \left[ \frac{a_\phi(0)-2\pi}{2\pi} \right] (ku, k\tau), \quad (2.25)$$

where we normalized $C$ as in eq. (2.18). This is exactly one of the (2.19) when we set $a_1(0)/2\pi = \mu/k$. Thus, we learn that to get an answer holomorphic in the complex structure $\tau$ we need a particular choice of canonical variables $(A_\phi, A_t)$, or equivalently a particular choice of eigenstate $|A_\phi\rangle$. In terms of the path integral $Z(A_z|\Sigma_R, a_\phi(0); \tau)$, this corresponds to a particular choice of the boundary term, namely: $f_B[A_1] = \tau \tau_2^{-1} A_1^2$.

**The gauge-invariant wave function.** Under a gauge transformation

$$A_z \longrightarrow ^\lambda A_z \equiv A_z - \partial_z \lambda, \quad (2.27)$$

a holomorphic wave function $\Psi[A_z]$ obtained from Kähler quantization transforms as $\Psi[A_z] \rightarrow (U(\lambda) \cdot \Psi)[A_z] \equiv \exp\left(-\frac{k}{2\pi} \int_\Sigma d^2 x \partial_2 \lambda \partial_2 \lambda + \frac{k}{\pi} \int_\Sigma d^2 x \partial_2 \lambda A_z \right) \Psi[^\lambda A_z]. \quad (2.28)$

Here $\lambda$ can include large gauge transformations. Thus, starting from any “seed” wave function $\Psi_0[A_z]$ we can integrate over the gauge group to construct a gauge-invariant wave function:

$$\Psi[A_z] \equiv \int D\lambda (U(\lambda) \cdot \Psi_0)[A_z]. \quad (2.29)$$
This formula includes a sum over large gauge transformations, so the most general $\lambda$ is

$$\lambda \equiv \lambda_0 + \lambda', \quad \text{ (2.30)}$$

where $\lambda_0$ is periodic on the torus, while the multivalued large gauge parameter $\lambda'$ enters in the integral only through its derivatives, which are single-valued on the torus; they are given by

$$\begin{align*}
\partial_2 \lambda' &= +i\pi(m + n\tau)\tau_2^{-1}, \\
\partial_2 \lambda' &= -i\pi(m + n\tau)\tau_2^{-1},
\end{align*}$$

(2.31)

If we take $(A_\xi | a_1(0)))$ to be a seed wave function $\Psi_0[A_\xi]$ which is not necessarily gauge-invariant and integrate over all gauge transformations including the large transformations $m, n \in \mathbb{Z}$, we reproduce the theta function in (2.19). To see this, we impose again the conditions (2.2) $A_\xi = \partial_\xi \chi + i\pi u\tau_2^{-1} \equiv \partial_\xi \chi + \partial_\xi \chi'$ and $a_\phi(0) = 2\pi \mu/k, \mu \in \mathbb{Z}$ and find

$$\int D'\lambda(U(\lambda) \cdot \Psi_0)[A_\xi]$$

\begin{align*}
&= \sum_{m,n \in \mathbb{Z}} \int D'\lambda_0 \exp \left( -\frac{k}{2\pi} \int_{\Sigma} d^2x \partial_1 \lambda_0 \partial_2 \lambda_0 + \frac{k}{\pi} \int_{\Sigma} d^2x A_\xi \partial_1 \lambda_0 \right) \\
&\quad \times \exp \left( -\frac{k}{2\pi} \int_{\Sigma} d^2x A_\xi - \frac{k}{2\pi} \int_{\Sigma} d^2x \partial_1 \lambda' \partial_2 \lambda' + \frac{k}{\pi} \int_{\Sigma} d^2x A_\xi \partial_2 \lambda' \right) \\
&\quad \times \exp \left( +\frac{k}{\pi} \int_{\Sigma} d^2x A_\xi a_1(0) - \frac{k}{\pi} \int_{\Sigma} d^2x \partial_1 \lambda a_1(0) + \frac{i k}{4\pi} \tau_2^{-1} \int_{\Sigma} d^2x (a_1(0))^2 \right) \\
&= \sum_{m,n \in \mathbb{Z}} C \int D'\lambda_0 \exp \left( -\frac{k}{2\pi} \int_{\Sigma} d^2x \partial_1 \lambda_0 \partial_2 \lambda_0 + \frac{k}{\pi} \int_{\Sigma} d^2x A_\xi \partial_1 \lambda_0 \right) \\
&\quad \times \exp \left( -\frac{k}{2\pi} \int_{\Sigma} d^2x A_\xi^2 + i\pi k m - 2\pi ik m \left( \frac{a_1(0)}{2\pi} \right) \right) \\
&\quad \times \exp \left( +2k \int_{\Sigma} d^2x A_\xi \left( \frac{a_1(0)}{2\pi} - n \right) + i\pi k \left( \frac{a_1(0)}{2\pi} - n \right) \tau \left( \frac{a_1(0)}{2\pi} - n \right) \right) \\
&= C \exp \left( +\frac{k}{2\pi} \int_{\Sigma} d^2x \partial_2 \chi \partial_1 \chi + \frac{k\pi}{2} u\tau_2^{-1} \right) \int D'\lambda_0 \exp \left( -\frac{k}{2\pi} \int_{\Sigma} d^2x \partial_2 \lambda_0 \partial_1 \lambda_0 \right) \\
&\quad \times \sum_{m,n \in \mathbb{Z}} \exp \left( i\pi k m n + 2\pi i ku \left( \frac{a_1(0)}{2\pi} - n \right) + i\pi k \left( \frac{a_1(0)}{2\pi} - n \right) \tau \left( \frac{a_1(0)}{2\pi} - n \right) \right) \\
&= e^{\frac{k}{2\pi} \int_{\Sigma} d^2x \partial_2 \chi \partial_1 \chi} \frac{e^{i\frac{k\pi}{2} u\tau_2^{-1} u}}{\eta(\tau)} \theta \left[ \frac{\mu}{k} \right] \left( ku, k\tau \right), \quad \text{ (2.36)}
\end{align*}$$

which is exactly $\mathcal{Z}(A_\xi; \mu; \tau)$ in (2.19). In arriving at (2.35), the constant $C$ was fixed as in (2.18) using the normalization condition $C \det^{-1/2}(-\frac{k}{2\pi} \partial_2 \partial_1) = \eta(\tau)^{-1}$ and we used that $k/2 \in \mathbb{Z}_{>0}, m \in \mathbb{Z}$ and $k a_1(0)/2\pi = \mu \in \mathbb{Z}$, so the summand does not depend on $m$.

Because of this, in the last line we discarded the infinite sum over $m \in \mathbb{Z}$. Similarly, the same calculation done with $(A_\xi | a_1(0))$ as seed wave function reproduces (2.17). Notice that discarding the sum over $m$ means simply to remove identical gauge copies from the
definition of the gauge-invariant wave function. This is a standard part of the construction of a gauge invariant, normalizable state or operator using an integral (and/or sum) over gauge transformations. Its analog in the context of three-dimensional gravity is explained for instance in [14].

2.1.1 Blowing up Wilson loops

One can insert into the path integral a gauge-invariant Wilson loop operator defined along a loop \( C \) on \( M \), as

\[
\hat{W}_\mu[C] \equiv \mathcal{P} \exp \left( i\mu \oint_C \hat{A} \right), \quad \mu \in \mathbb{Z}.
\] (2.37)

\( \mathcal{P} \) means path-ordering, and the U(1) charge \( \mu \) is integer-valued such that \( \hat{W}_\mu[C] \) is invariant under large gauge transformations defined on \( C \). We restrict \( C \) to be a path that runs along the non-contractible cycle of \( M \), and without loss of generality put it at the origin \( r = 0 \) of the solid torus.

We would like to map \( \hat{W}_\mu[C] \) to a “blown-up” operator in radial quantization, which acts on a state defined on \( \Sigma \). To this end, recall that the \( A_1 \)-eigenstate \( |A_1\rangle \) is the translation of the \( A_1 = 0 \) eigenstate \( |0\rangle \) by the operator \( \hat{A}_2 \) given in (2.9),

\[
|A_1\rangle \equiv \exp \left( +\frac{ik}{2\pi} \int_{\Sigma} d^2x \hat{A}_2 \right) |0\rangle.
\] (2.38)

The initial surface \( \Sigma_0 \) is degenerate but the Wilson loop operator \( \hat{W}_\mu[C_2] \), with \( C_2 \) at \( r = 0 \) running along the \( x^2 \)-direction, can be “blown-up” and identified with the translation operator defined in (2.38) acting on the Hilbert space on \( \Sigma \),

\[
\hat{W}_\mu[C_2] = \mathcal{P} \exp \left( i\mu \oint_{C_2} dx^2 \hat{A}_2 \right)
\] (2.39)

\[
\rightarrow \hat{W}_\mu[\Sigma, 2] \equiv \exp \left( i \int_{\Sigma} d^2x \mu \hat{A}_2 \right) = \exp \left( i \int_{\Sigma} d^2x \left( i\mu \hat{A}_z - i\mu \hat{A}_\bar{z} \right) \right).
\] (2.40)

Alternatively, choosing \( A_t \) as the conjugate momentum from (2.22) we have

\[
|A_\phi\rangle \equiv \exp \left( +\frac{ik}{2\pi} \tau_2^{-1} \int_{\Sigma} d^2x \hat{A}_t A_\phi \right) |0\rangle.
\] (2.41)

We can also define a “blown-up” version of the Wilson loop operator \( \hat{W}_\mu[C_t] \), with \( C_t \) at \( r = 0 \) running along the \( t \)-direction, and identify it with the translation operator in (2.41),

\[
\hat{W}_\mu[C_t] = \mathcal{P} \exp \left( i\mu \int_0^1 dt \hat{A}_t \right)
\] (2.42)

\[
\rightarrow \hat{W}_\mu[\Sigma, t] \equiv \exp \left( i\tau_2^{-1} \int_{\Sigma} d^2x \mu \hat{A}_t \right) = \exp \left( i \int_{\Sigma} d^2x \left( \tau \tau_2^{-1} \mu \hat{A}_z + \bar{\tau} \tau_2^{-1} \mu \hat{A}_{\bar{z}} \right) \right).
\] (2.43)

Gauge invariance and framing. Both \( C_2 \) and \( C_t \) trace the same closed loop at the origin, though with twists differing by \( \tau_1 \). One may wish to assign a framing to this loop by defining a vector field on it [1, 24], thereby extending this loop into a ribbon. Such a
vector field must be periodic under the global identification \((x^1, x^2) \sim (x^1 + \tau_1, x^2 + \tau_2)\) — now that we are away from the degenerate \(r = 0\) surface. The simplest choice is that corresponding to \(C_t\), while that corresponding to \(C_2\) does not respect the periodicity.

In the language of the “blowing-up” procedure, this fact translates to demanding that the “blown-up” Wilson loop operator on \(\Sigma\) must be gauge-invariant. Both of the original Wilson loops \(\hat{W}_\mu[C_2]\) and \(\hat{W}_\mu[C_t]\) are invariant under gauge transformations defined on the loops. But among their “blown-up” versions, only \(\hat{W}_\mu[\Sigma, t]\) is gauge-invariant on \(\Sigma\). \(\hat{W}_\mu[\Sigma, 2]\) is not invariant under large transformations with a non-trivial winding along the \(\phi\)-direction, which were not well-defined transformations on the original loop \(C_2\). Gauge invariance thus selects \(\hat{W}_\mu[\Sigma, t]\) as the preferred operator on \(\Sigma\).

Note that the \(\hat{W}_\mu[\Sigma, t], \mu \in \mathbb{Z}\), are not the only gauge-invariant operators. The most general gauge invariant “blown-up” operator on \(\Sigma\) with constant coefficients\(^4\) takes the form

\[
\hat{W}[\Sigma; \mu, N] = \exp \left( i \mu \int_\Sigma d^2x \left( \tau \tau_2^{-1} \hat{A}_z + \tau_2^{-1} \hat{A}_z \right) + i N \tau_2^{-1} \int_\Sigma d^2x \left( \hat{A}_z + \hat{A}_\xi \right) \right) \tag{2.44}
\]

where we used a special case of the Baker-Campbell-Hausdorff formula:

\[
\text{if } [X, [X, Y]] = 0 = [Y, [X, Y]], \text{ then } e^{X+Y} = e^X e^Y e^{-\frac{1}{2}[X,Y]}, \tag{2.46}
\]

and the canonical commutation relation (2.8b) to arrive at this result. That is, \(\hat{W}[\Sigma; \mu, N]\) is equivalent to blowing up the loop \(C_t\) together with the loop \(C_\phi\) along the \(\phi\)-direction. So we can identify the pure phase as due to the linking of these two loops \([1]\). Since \(\hat{W}[\Sigma; \mu, N]\) is gauge-invariant, we can commute it with the integral over gauge transformations (2.29), and let it act on the seed wave function \(\Psi_0[A_z] = (A_z|0\rangle\), which is an eigenvector of \(\hat{A}_\phi\) with eigenvalue \(A_\phi = 0\). The result reads

\[
\hat{W}[\Sigma; \mu, N](A_z|0\rangle) = e^{+ \frac{i \mu}{k} \phi} \hat{W}[\Sigma, t](A_z|0\rangle) = e^{+ \frac{i \mu}{k} \phi} (A_z|2\pi \mu/k\rangle). \tag{2.47}
\]

The integral (2.29) is then

\[
\int D\lambda \left( U(\lambda) \cdot \hat{W}[\Sigma; \mu, N](A_z|0\rangle) \right) = e^{+ \frac{i \mu}{k} \phi} \int D\lambda \left( U(\lambda) \cdot \left( A_z|2\pi \mu/k\rangle \right) \right) \tag{2.48}
\]

\[
= e^{+ \frac{i \mu}{k} \phi} \int \eta(\tau) d^2x \hat{A}_\phi \left[ \frac{\mu}{k} \right] (ku, k\tau). \tag{2.49}
\]

Thus, the only contribution of the \(N\)-dependent term in \(\hat{W}[\Sigma; \mu, N]\) to the gauge-invariant wave function is a pure phase proportional to the linking number. This is expected from general principles of canonical quantization, because the Wilson loops \(\hat{W}_\mu[C_t], \mu \in \mathbb{Z}\), already span the full Hilbert space, and so the Wilson loop operators along \(C_\phi\) can at most contribute a pure phase \([25]\). Note that in the special case \(N = \mu N', N' \in \mathbb{Z}\), \(\hat{W}_\mu[C_t]\) also span the full Hilbert space, and so the Wilson loop operators along \(C_\phi\) can at most contribute a pure phase \([25]\).
\[ \hat{W}[\Sigma; \mu, N = \mu N'] \] can be regarded as the blowing-up of the loop \( C_t \) with additional \( N' \) twists. The phase

\[ \exp \left( +i\frac{\pi}{\mu N} \right) = \exp \left( +i\pi N' \frac{\mu^2}{k} \right) \]  

is then identified with the framing anomaly [1].

2.2 Higher genus

For partition functions on higher-genus handlebodies, it is convenient to make use of certain special quadratic differentials on Riemann surfaces, reviewed in appendix B. Specifically, we pick a Strebel differential \( \varphi \), which is a quadratic differential on the Riemann surface \( \Sigma \), holomorphic in the complex structure; locally, \( \varphi = h(z)dz^2 \) where \( h(z) \) is holomorphic. The existence of such differentials is proven in [22]. We do not need to know their precise form. All we need from a Strebel differential is the fact that it foliates the Riemann surface \( \Sigma \) into horizontal trajectories, which are closed curves given by

\[ f(p) \equiv \int^p \sqrt{h}dz - \int^p \sqrt{h^*}d\bar{z} = \text{constant}. \]  

The Strebel differential \( \varphi \) also defines a metric on \( \Sigma \), which takes the form

\[ g_{\bar{z}z} = \sqrt{hh^*} = \sqrt{g}. \]  

This metric may have zeros or singularities, which define the singular points of the foliation. We define next a vector field \( v \) of unit norm with respect to (2.52), whose integral curves are the horizontal trajectories so that \( v(f) \equiv 0 \):

\[ v \equiv v(z)\partial_z + \bar{v}(\bar{z})\partial_{\bar{z}} = \frac{1}{\sqrt{h}}\partial_z + \frac{1}{\sqrt{h^*}}\partial_{\bar{z}} \equiv \partial_h. \]  

We use the vector field \( v \) to define cycles on a higher-genus Riemann surface \( \Sigma \), that are contractible on the corresponding handlebody \( M \). On the torus, \( v = \bar{v} = 1 \) and \( \partial_h = \partial_1 \). The square root in (2.53) can cause generically an obstruction to defining a global holomorphic vector field on \( \Sigma \). On the other hand, we do not need \( v \) to be holomorphic, so we can always rescale \( v \) by a common factor: \( v \rightarrow \epsilon v \) with \( \epsilon \) a smooth real function. The equations that we will find in the next subsections depend only on the ratio \( \bar{v}/v \), which is not affected by the rescaling. The function \( \epsilon \) can even vanish on subsets of measure zero that are transverse to the horizontal trajectories without altering the ratio \( \bar{v}/v \). By making \( \epsilon \) vanish somewhere on \( \Sigma \), a nonholomorphic vector field can be defined everywhere on \( \Sigma \).

The horizontal trajectories and the vector field \( v \) that generates them are illustrated schematically in figure 1.

2.2.1 The vacuum partition function

We would like to generalize the third approach used in the torus case: start from a non-gauge invariant seed wave function \( \Psi_0[A_2] \) and integrate over the gauge orbit to arrive at a gauge-invariant wave function. The most natural and simplest seed wave function is
the eigenstate of trivial holonomy along the contractible cycles, $\Psi_0[A_{\bar{z}}]$, computed in the coherent state basis $(A_{\bar{z}})$. In terms of the vector field $v$ that generates the closed horizontal trajectories, it is defined by

$$\Psi_0[A_{\bar{z}}] = C \exp \left( -\frac{k}{2\pi} \int_{\Sigma} d^2x \left( \frac{1}{v} \bar{v} A_{\bar{z}} - \frac{1}{v} A_{\bar{z}}^2 \right) \right).$$

As for genus one, here the constant $C$ may depend on the complex structure and is fixed by properly normalizing the vacuum partition function. We show next that integrating it over the gauge orbit does result in a particular vector in the Hilbert space (2.1) obtained from Kähler quantization, holomorphic in the complex structure $\Omega$. In particular, we will see that, after integration, the vector $v$ appears only in the Weyl anomaly.

Given any seed wave function $\Psi_0$, the gauge integral is given by a generalization of (2.29) on the torus. It reads

$$\Psi[A_{\bar{z}}] \equiv \int D\lambda U(\lambda) \cdot [A_{\bar{z}}]$$

where $A_{\bar{z}} \rightarrow \lambda A_{\bar{z}} \equiv A_{\bar{z}} - \partial_{\bar{z}} \lambda$.

We begin by decomposing

$$A_{\bar{z}} = \partial_{\bar{z}} \chi + \partial_{\bar{z}} \chi' \equiv \partial_{\bar{z}} \chi + i\pi u (\text{Im} \Omega)^{-1} \varpi(\bar{z}), \quad \varpi \equiv \varpi(\bar{z}) d\bar{z},$$

$$\lambda = \lambda_0 + \lambda',$$

$$\partial_{\bar{z}} \lambda' = i\pi (m + n\Omega)(\text{Im} \Omega)^{-1} \varpi(\bar{z}), \quad \partial_{\bar{z}} \lambda' = -i\pi (m + n\Omega)(\text{Im} \Omega)^{-1} \omega(z),$$

$$U(\varpi(\bar{z})) \equiv \partial_{\bar{z}} \chi' - \partial_{\bar{z}} \lambda' = i\pi (u - (m + n\Omega))(\text{Im} \Omega)^{-1} \varpi(\bar{z}), \quad m, n \in \mathbb{Z}^g,$$

where both $\chi$, $\lambda_0$ are single-valued on $\Sigma$. The multivalued function $\lambda'$ appears everywhere only through its derivatives, which are also single-valued on $\Sigma$. Next we evaluate the
Thus, we see that the vector field $v$.

(On the torus, this reduces to (2.33) with $a_1(0) = 0$). Let us look now at the terms involving $\lambda_0$:

$$S \equiv \ln \left( (U(\lambda) \cdot \Psi_0) + \log C \right)$$

$$= -\frac{k}{2\pi} \int d^2x \partial_z \lambda \partial_{\bar{z}} \lambda + \frac{k}{\pi} \int d^2x \partial_{\bar{z}} \lambda A_z - \frac{k}{2\pi} \int d^2x \frac{\tilde{v}}{v} (A_{\bar{z}} - \partial_{\bar{z}} \lambda)^2$$

$$= -\frac{k}{2\pi} \int d^2x \frac{1}{v} \partial_{\bar{z}} \lambda_0 \partial_{\bar{z}} \lambda_0 + \frac{k}{\pi} \int d^2x \frac{1}{v} \partial_{\bar{z}} \lambda_0 \partial_{\bar{z}} \chi + \frac{k}{\pi} \int d^2x \frac{1}{v} \partial_{\bar{z}} \lambda_0 U\varpi(\bar{z})$$

$$= -\frac{k}{2\pi} \int d^2x \frac{1}{v} \left[ \partial_{\bar{z}} \lambda' \partial_{\bar{z}} \lambda' - 2 \partial_{\bar{z}} \lambda' \partial_{\bar{z}} \chi + \partial_{\bar{z}} \chi \partial_{\bar{z}} \chi + 2 \partial_{\bar{z}} \lambda \partial_{\bar{z}} \chi' + \partial_{\bar{z}} \chi' \partial_{\bar{z}} \lambda' \right] .$$

Since $\tilde{S}$ is quadratic, the $\lambda_0$-integral in (2.57) can be evaluated exactly. The saddle point $\lambda_{0,cl}$ at which $\tilde{S}$ extremal satisfies the equation of motion

$$\partial_{\bar{z}} \left[ \partial_{\bar{z}} (\lambda_{0,cl} - \chi) - \tilde{v} U\varpi(\bar{z}) \right] = 0 .$$

In addition, we recall that any horizontal trajectory $\gamma(s) \sim \sum_i N_i a_i$ is homologous to a linear combination of the $a$-cycles and that the trajectory is an integral curve of the vector $v$, so that $v(z(s)) = \frac{dz}{ds}$. We thus have $f_\chi \partial_{\bar{z}} (\lambda_{0,cl} - \chi) = 0$, since $\lambda_{0,cl}$ and $\chi$ are periodic. Then (2.62) is integrated to

$$\partial_{\bar{z}} (\lambda_{0,cl} - \chi) = -v U\varpi(\bar{z}) + \tilde{v} U\varpi(\bar{z}) .$$

Substituting (2.63) back into the action (2.61) and including the fluctuation $f$ around the saddle point $\lambda_{0,cl}$, the action $S$ becomes

$$S = -\frac{k}{2\pi} \int d^2x \frac{1}{v} \partial_{\bar{z}} f \partial_{\bar{z}} f + \frac{k}{2\pi} \int d^2x \partial_{\bar{z}} \chi \partial_{\bar{z}} \chi$$

$$= -\frac{k}{2\pi} \int d^2x U\varpi(z) U\varpi(\bar{z}) - \frac{k}{2\pi} \int d^2x \partial_{\bar{z}} \lambda' \partial_{\bar{z}} \lambda' + \frac{k}{\pi} \int d^2x \partial_{\bar{z}} \lambda \partial_{\bar{z}} \lambda' .$$

Thus, we see that the vector field $v$ indeed drops out, except in the fluctuation term.

Substituting the definitions (2.58) into $\Psi[A_{\bar{z}}]$ and repeating the same calculation done in the torus case, we arrive at

$$\Psi[A_{\bar{z}}] \equiv \int D\bar{\lambda} (U(\lambda) \cdot \Psi_0) [A_{\bar{z}}]$$

$$= C \det -\frac{1}{i} \left( -\frac{k}{2\pi} \partial_{\bar{z}} \partial_{\bar{z}} \right) e^\frac{k\pi u (\text{Im}\Omega)^{-1} u + \frac{k}{\pi} \int d^2x \partial_{\bar{z}} \chi \partial_{\bar{z}} \chi}{F(\bar{\Omega})^{\frac{1}{2}}} \theta \left[ \begin{array}{c} 0 \\ 0 \end{array} \right] (ku, k\Omega) ,$$

(2.67)
which is (2.1) with \( \mu = 0 \). When computing the quadratic functional integral over the fluctuations \( f \) (with the zero modes discarded), we used again the freedom in choosing the constant \( C \) to ensure that the wave function is a section of a projectively flat bundle over the complex structure moduli space. For Abelian Chern-Simons theories, this is achieved by using the factorization of the Laplacian (2.3) (or by comparison with the formulas in [16]), which results in \( C \det^{-1/2} \left(-\frac{k}{\pi} \partial_\bar{z} \partial_z\right) = 1/F(\Omega)^{\frac{1}{2}} \). Note that the constant \( C \) also reabsors a term that contains a Weyl anomaly and therefore, because of (2.53), a dependence on \( v \). We also used \( k/2 \in \mathbb{Z} \) and \( m,n \in \mathbb{Z}^g \), and discarded the trivial sum over \( m \), that is the sum over large gauge transformations that can be extended to the bulk and under which the wave function is invariant.

### 2.2.2 Wilson loops

On a higher-genus handlebody, besides Wilson loops that can be regarded as “world histories of mesons,” there is also another class of gauge-invariant observables, which correspond to the “world histories of baryons” running along the non-contractible cycles; see [24]. For the Abelian case that we have considered here, however, the fusion rule is trivial, so those “baryon world histories” can be decomposed into disjoint Wilson loops running along the non-contractible cycles of the handlebody. Therefore, it suffices to consider only standard Wilson loops.

We would like to generalize the “blowing-up” of Wilson loops that we studied on the torus in section 2.1.1 to higher genus. Consider the loops \( C_I \) running along the \( g \) non-contractible cycles of \( M \) and endowed with charges \( \mu_I \in \mathbb{Z}^k \). The resulting Wilson loops are then “blown up” into operators \( \hat{W}[\Sigma, w] \) on \( \Sigma \), parametrized by real one-forms

\[
\begin{align*}
  w = (w_0 dz + w'_0 d\bar{z}) + (\bar{w}_0 d\bar{z} + \bar{w}'_0 dz) &\equiv w_0 + w', \\
  \equiv w_0 dz + (\bar{w}_0 d\bar{z} + \bar{w}'_0 dz) &\equiv w_0 + w',
\end{align*}
\]

(2.68)

where the \( w_0 \) are periodic on \( \Sigma \) and \( w'_I \) are constant. A “blown-up” Wilson loop operator is then

\[
\hat{W}[\Sigma, w] \equiv \exp \left( i \int_{\Sigma} d^2 x (\bar{w} A_z + w \bar{A}_z) \right),
\]

(2.69)

Importantly, gauge invariance of \( \hat{W}[\Sigma, w] \) demands that

\[
\begin{align*}
  \partial_z \bar{w}_0 + \partial_\bar{z} w_0 &= 0 \quad \Rightarrow \quad w_0 = i \partial_z \eta, \\
  \int_{\Sigma} d^2 x (\bar{w}' A_z + w' \bar{A}_z) &\equiv 2\pi \mathbb{Z}.
\end{align*}
\]

(2.70)

Here \( \eta \) is a real single-valued function on \( \Sigma \), and \( \lambda' \) is a large gauge transformation (2.58). As discussed in section 2.1.1, by demanding large gauge invariance on the “blown-up” surface one selects a class of preferred framings, satisfying

\[
-i\pi m(\bar{w}' - w') + i\pi n(\Omega w' - \Omega \bar{w}') \in 2\pi \mathbb{Z}.
\]

(2.71)

Inverting this condition yields

\[
\bar{w}' = (\text{Im} \Omega)^{-1}(\Omega \mu + N), \quad \mu, N \in \mathbb{Z}^g.
\]

(2.72)

For \( \eta = 0 \) on the torus, we recover the Wilson loop \( \hat{W}[\Sigma; \mu, N] \) in (2.44).
The saddle point

The terms containing

We repeat the calculation done in the last subsection to evaluate the gauge integral (2.56).

Using again the Baker-Campbell-Hausdorff formula (2.46), one gets

\[ \Psi_{\omega,0}[A_\tilde{z}] \equiv \hat{W}[\Sigma, w] \Psi_0[A_\tilde{z}] \]

\[ = C \exp \left( -\frac{k}{2\pi} \int_\Sigma d^2x \frac{\bar{v}}{v} A_\tilde{z}^2 \right) \]

(2.73)

We repeat the calculation done in the last subsection to evaluate the gauge integral (2.56).

The integrand is

\[ S \equiv \ln \left( U(\lambda) \cdot \Psi_{\omega,0} \right) - \log(C) \tag{2.76} \]

\[ = -\frac{k}{2\pi} \int_\Sigma d^2x \partial_\lambda \partial_\bar{\lambda} + \frac{k}{\pi} \int_\Sigma d^2x \partial_\lambda A_\tilde{z} \]

\[ - \frac{k}{2\pi} \int_\Sigma d^2x \frac{\bar{v}}{v} (A_\tilde{z} - \partial_\tilde{z})^2 \]

\[ = -\frac{k}{2\pi} \int_\Sigma d^2x \frac{1}{v} \partial_\lambda \lambda_0 \partial_\bar{\lambda} + \frac{k}{\pi} \int_\Sigma d^2x \frac{1}{v} \partial_\lambda \lambda_0 (\partial_\tilde{z} \lambda + U \bar{\omega}(\bar{z})) \]

\[ + i \int_\Sigma d^2x \partial_\lambda \lambda_0 \left[ \frac{\bar{w}(\bar{v})}{v} - w \right] - \frac{k}{2\pi} \int_\Sigma d^2x \partial_\lambda \lambda' \partial_\bar{\lambda} \lambda' + \frac{k}{\pi} \int_\Sigma d^2x \partial_\lambda \lambda' \partial_\bar{\lambda}' \lambda' \]

\[ + i \int_\Sigma d^2x \partial_\lambda \lambda' \left[ \frac{\bar{w}(\bar{v})}{v} - w \right] - i \int_\Sigma d^2x \left[ \frac{\bar{w}(\bar{v})}{v} - w \right] A_\tilde{z} \]

\[ + \frac{\pi}{2k} \int_\Sigma d^2x \bar{w} \left[ \frac{\bar{w}(\bar{v})}{v} - w \right] \]

\[ - \frac{k}{2\pi} \int_\Sigma d^2x \frac{\bar{v}}{v} \left[ \partial_\lambda \lambda_0 \partial_\bar{\lambda} + 2 \partial_\tilde{z} \lambda_0 \partial_\bar{\lambda} + U \omega(z) \bar{\omega}(\bar{z}) - 2 \partial_\bar{\lambda} \lambda_0 \partial_\lambda \right]. \tag{2.78} \]

The terms containing \( \lambda_0 \) are

\[ \tilde{S} \equiv -\frac{k}{2\pi} \int_\Sigma d^2x \frac{1}{v} \partial_\lambda \lambda_0 \partial_\bar{\lambda} + \frac{k}{\pi} \int_\Sigma d^2x \partial_\lambda \lambda_0 \partial_\bar{\lambda} \]

\[ + \frac{k}{\pi} \int_\Sigma d^2x \partial_\lambda \lambda_0 \left( \frac{\bar{v}}{v} \partial_\lambda + \frac{U}{v} \bar{\omega}(\bar{z}) - \frac{i\pi}{k} w + \frac{i\pi}{k} \bar{w} \right) \]

\[ = -\frac{k}{2\pi} \int_\Sigma d^2x \frac{1}{v} \partial_\lambda \lambda_0 \partial_\bar{\lambda} + \frac{k}{\pi} \int_\Sigma d^2x \partial_\lambda \lambda_0 \partial_\bar{\lambda} \left( \chi + \frac{\pi}{k} \eta \right) \]

\[ + \frac{k}{\pi} \int_\Sigma d^2x \frac{\bar{v}}{v} \partial_\lambda \lambda_0 \left( \partial_\bar{\lambda} \left( \chi + \frac{\pi}{k} \eta \right) + \left( U + \frac{i\pi}{k} w' \right) \bar{\omega}(\bar{z}) \right). \tag{2.79} \]

The saddle point \( \lambda_{0, cl} \) at which \( \tilde{S} \) is extremal satisfies the equation of motion

\[ \partial_\bar{\lambda} \left[ \partial_\lambda \left( \lambda_{0, cl} - \chi - \frac{\pi}{k} \eta \right) - \bar{v} \left( U + \frac{i\pi}{k} w' \right) \bar{\omega}(\bar{z}) \right] = 0, \tag{2.81} \]
which is integrated to
\[ \partial_h \lambda_{0,cl} = \partial_h \left( \chi + \frac{\pi}{k} \eta \right) - v \left( \mathcal{U} + \frac{i\pi}{k} \bar{w}' \right) \omega(z) + \bar{v} \left( \mathcal{U} + \frac{i\pi}{k} w' \right) \bar{\omega}(\bar{z}). \] (2.82)

Substituting (2.82) back to the action (2.80) and including the fluctuation \( f \) around the saddle point, we get
\[ S = -\frac{k}{2\pi} \int \Sigma d^2 x \frac{1}{v} \partial_h f \partial_z f + \frac{k}{2\pi} \int \Sigma d^2 x \partial_z \chi \partial_z \chi \] (2.83)
\[ - \frac{k}{2\pi} \int \Sigma d^2 x \mathcal{U}(z) \bar{\omega}(\bar{z}) - \frac{k}{2\pi} \int \Sigma d^2 x \partial_z \lambda' \partial_z \lambda' \] (2.84)
\[ - i \int \Sigma d^2 x \mathcal{U}(z) (\bar{w}' - w') \omega(z) + \frac{\pi}{2k} \int \Sigma d^2 x (\bar{w}' - w') \omega(z) \bar{\omega}(\bar{z}). \]

So, once again, \( v \) drops out of the action—except in the fluctuation term which also gives the Weyl anomaly. Moreover, the function \( \eta \) in \( w \) drops out as well. Evaluating the path integral in the same way as before, we finally get
\[ \Psi_w[A_{\bar{z}}] \equiv \int D' \lambda (U(\lambda) \cdot \Psi_w,0)|A_{\bar{z}} \rangle \] (2.85)
\[ = C \det^{-1/2} \left( -\frac{k}{2\pi} \partial_z \partial_{\bar{z}} \right) e^{+\frac{i\pi}{2} u (\text{Im} \Omega)^{-1} u} \int \Sigma d^2 x \partial_z \lambda \partial_{\bar{z}} \lambda \]
\[ \times \sum_{m,n \in \mathbb{Z}^g} \exp \left( -2\pi iku + i\pi k(m + n\Omega) \right) \]
\[ \times \exp \left( +2\pi i\mu - 2\pi i\mu - i\pi n \Omega \mu + \frac{\pi}{2k} (2i\mu)(\Omega \mu + N) \right) \]
\[ = e^{+\frac{i\pi}{2} \int \Sigma d^2 x \partial_z \lambda \partial_{\bar{z}} \lambda} e^{+\frac{k\pi}{2} \frac{u (\text{Im} \Omega)^{-1} u}{F(\Omega)^{1/2}} \text{exp} \left[ \frac{k}{0} \right]} (ku, k\Omega) e^{\frac{i\pi}{2} \mu N}. \] (2.86)

Here used the same normalization for \( C \) as in eq. (2.67) together with \( k/2 \in \mathbb{Z}, m, n \in \mathbb{Z}^g \) and \( \mu \in \mathbb{Z} \), and discarded the trivial sum over \( m \).

Since \( \eta \) drops out eventually, we can repeat the analysis we performed in the torus case. Namely,
\[ \hat{W}[\Sigma, w'] = \exp \left( i \int \Sigma d^2 x (\bar{w}' A_z + w' \bar{A}_z) \right), \quad \hat{W}[\Sigma, w'] = (\text{Im} \Omega)^{-1}(\Omega \mu + N), \mu, N \in \mathbb{Z}^g \] (2.87)
\[ = \exp \left[ i\mu \int \Sigma d^2 x \left( \text{Im} \Omega \right)^{-1} \bar{\omega}(\bar{z}) \hat{A}_z + \bar{\Omega}(\text{Im} \Omega)^{-1} \omega(z) \hat{A}_z \right] \] (2.88)
\[ + iN (\text{Im} \Omega)^{-1} \int \Sigma d^2 x \left( \bar{\omega}(\bar{z}) \hat{A}_z + \omega(z) \hat{A}_z \right) \]
\[ = \exp \left[ i\mu \int \Sigma d^2 x \left( \text{Im} \Omega \right)^{-1} \bar{\omega}(\bar{z}) \hat{A}_z + \bar{\Omega}(\text{Im} \Omega)^{-1} \omega(z) \hat{A}_z \right] \] (2.89)
\[ \times \exp \left[ + iN (\text{Im} \Omega)^{-1} \int \Sigma d^2 x \left( \bar{\omega}(\bar{z}) \hat{A}_z + \omega(z) \hat{A}_z \right) \exp \left[ + \frac{i\pi}{k} \mu N \right] \right] \]
\[ \equiv \hat{W}[\Sigma, \mu] \hat{W}[\Sigma, N] e^{+\frac{i\pi}{2} \mu N}. \] (2.90)
non-contractible and contractible cycles of \( M \). The only contribution of \( \hat{W}[\Sigma, N] \) to a gauge-invariant wave function is the phase \( \exp(+i\pi/k)\mu N \) and is due to the linking of the loops. In the special case \( N_I = N_{I,J} \mu_J \) for some symmetric matrix \( N' \) with integer entries, this phase \( \exp(+i\pi/k)\mu N' \mu \) is naturally interpreted as the framing anomaly.

3 The non-Abelian case

We consider now the non-Abelian case, with a compact, simply-connected and simple Lie group \( G \) on a solid torus. In this section \( M \) is always the torus handlebody and \( \Sigma = T^2 \).

By generalizing the equation (2.24) found in the Abelian case, we will consider the \( G \) group. We consider now the non-Abelian case, with a compact, simply-connected and simple Lie group \( G \).

The amplitude with \( A_\phi|\Sigma_0 = a_\phi(0) \) constant is

\[
(A_z|e^{-iHR}|a_\phi(0)) = 
\begin{aligned}
&= \int_{A_\phi|\Sigma_0 = a_\phi(0)} DA_1 DA_2 \delta(F_{12}) e^{iI} \\
&= C \int_{A_\phi|\Sigma_0 = a_\phi(0)} DA_1 DA_2 \delta(F_{12}) \\
&\quad \times \exp \left( + \frac{k}{2\pi} \int_{\Sigma R} d^2x Tr A_2^2 - \frac{k}{\pi} \int_{\Sigma R} d^2x Tr A_2 A_\phi(R) \right) \\
&\quad \times \exp \left( - \frac{ik}{4\pi} \tau_2^{-1} \int_{\Sigma R} d^2x (A_\phi(R))^2 \right) \exp \left( + \frac{ik}{2\pi} \int_{M} d^2x dr Tr A_t \partial_r A_\phi \right). 
\end{aligned}
\] (3.1)

Solving the constraint \( F_{12} = 0 \) by [17]

\[ A_t = g^{-1} a_t g + g^{-1} \partial_t g, \ a_i : [0, R] \to G, \ g : [0, R] \times \Sigma \to G, \ i = \phi, t, \] (3.4)

the action (3.3) becomes

\[
iI = \frac{k}{2\pi} \int_{\Sigma R} d^2x Tr A_2^2 - \frac{ik}{12\pi} \int_{M} d^2x dr Tr [(g^{-1}dg)^3] - \frac{ik}{4\pi} \tau_2^{-1} \int_{\Sigma R} d^2x Tr (a_\phi(R))^2 \\
+ \frac{k}{2\pi} \int_{\Sigma R} d^2x Tr [g \partial_\phi ((\partial_\Sigma + 2A_\Sigma)g^{-1})] + 2 \frac{k}{2\pi} \int_{\Sigma R} d^2x Tr [a_\phi(R) g(\partial_\Sigma + A_\Sigma) g^{-1}] \\
+ \frac{ik}{2\pi} \int_{M} d^2x dr Tr [- (a_\phi a_t - a_t a_\phi) \partial_t gg^{-1} + a_t \partial_r a_\phi] + \log(C). \] (3.5)

On the torus \( a_\phi(r) \) and \( a_t(r) \) commute so they are elements of the Cartan subalgebra \( \mathfrak{h} \) of \( \mathfrak{g} \): this is not true in general for higher genus. Moreover, by integrating out \( a_t(r) \) we get
\(a_\phi(r) = a_\phi(0)\), so the amplitude (3.3) becomes

\[
(A_\bar{z}|e^{-iHR}|a_\phi(0)) = Z(A_\bar{z}, a_\phi(0); \tau) = \int Dg e^{iI},
\]

\[
iI = -\frac{ik}{12\pi} \int_M d^2 x d r \text{Tr} [ (g^{-1}dg)^3 ] + \frac{k}{2\pi} \int_{\Sigma_R} d^2 x Tr A_\bar{z}^2
\]

\[
- \frac{ik}{4\pi} \tau^{-1} \int_{\Sigma_R} d^2 x Tr (a_\phi(R))^2 + \frac{k}{2\pi} \int_{\Sigma_R} d^2 x Tr [g\partial_\phi((\partial_\bar{z} + 2A_\bar{z})g^{-1})]
\]

\[
- \frac{2k}{2\pi} \int_{\Sigma_R} d^2 x Tr [a_\phi(R)g(\partial_\bar{z} + A_\bar{z})g^{-1}] + \log(C).
\]

With an appropriate, \(A_\bar{z}\)-independent choice of \(C\), this is the chiral Wess-Zumino-Witten path integral. For \(a_\phi(0) = 2\pi \mu/k\) where \(\mu\) is an integral weight of \(G\) and \(A_\bar{z} = iu\tau_2^{-1}\), ref. [26] shows that the path integral gives the Weyl-Kac character\(\chi_{\mu,k}(u, \tau)\):

\[
(A_\bar{z}|e^{-iHR}|2\pi \mu/k) = e^{-\frac{i\mu}{\pi} \text{Tr} [u\tau_2^{-1}]} \chi_{\mu,k}(u, \tau) = e^{-\frac{i\mu}{\pi} \text{Tr} [u\tau_2^{-1}]} \frac{\theta^{-}_{\mu+p,k+h^\vee}(u, \tau)}{\theta^{-}_{\mu,h^\vee}(u, \tau)},
\]

where \(\rho\) and \(h^\vee\) are respectively the Weyl vector and the dual Coxeter number of \(g\). The Weyl-odd theta function is defined as

\[
\theta^{-}_{\mu,k}(u, \tau) = \sum_{w \in W} \epsilon(w) \theta_{\mu,k}(w(u), \tau)
\]

where \(W\) is the Weyl group of \(G\) and \(\epsilon(w)\) is the signature of \(w \in W\). \(\theta_{\mu,k}(u, \tau)\) is the level-\(k\) theta function for the Lie algebra \(g\), whose definition is recalled in (A.3).

### 3.1 Wilson loops

The Wilson loop operator of the representation generated by the integral highest weight \(\mu\) of \(G\), along a loop \(C\) of constant radius in \(M\), is

\[
\hat{W}_{\mu}[C] \equiv \text{Tr}_\mu \mathcal{P} \exp \left( \oint_C \hat{A} \right) = \text{Tr}_\mu \mathcal{P} \exp \left( \oint_C \hat{a} \right).
\]

In the last equality, we stripped off the pure gauge part of \(\hat{A}\) (recall the definition \(A_i = g^{-1}a_i g + g^{-1} \partial_i g\)) due to the trace in the definition of \(\hat{W}_{\mu}[C]\), so we only need to look at the equal-radius canonical commutation relation of \(\hat{a}_i(r)\), which we read off from (3.5):

\[
[\hat{a}_j^+(r), \hat{a}_l^-(r)] = -\frac{2\pi}{k} \delta_{jl}.
\]

Here we have expanded \(a_{\phi,t}(r) = \sum_{j=1}^{\text{rank}(g)} a_{\phi,t}^j(r) H^j\) in the Cartan-Weyl basis \(\{H^j\}\) of the Cartan subalgebra \(h\) of \(g\), where \(j, l = 1, \ldots, \text{rank}(g)\). For the loop \(C_t\) at \(r = 0\) running along the \(t\)-direction,

\[
\hat{W}_{\mu}[C_t] = \text{Tr}_\mu \mathcal{P} \exp \left( \oint_{C_t} \hat{a} \right).
\]

As in the Abelian case, we map (3.12) to a “blown up” gauge-invariant operator \(\hat{W}_\mu[\Sigma]\) defined on \(\Sigma\), which is to be identified with the translation operator by the conjugate
momentum $a^\mu_\ell$, acting on the $a_\phi = 0$ eigenstate $|0\rangle$. Since $\hat{a}_t$ is constant on $\Sigma$, the Wilson loop is simply given by

$$\hat{W}_\mu[C_t] \longrightarrow \hat{W}_\mu[\Sigma] \equiv \text{Tr}_\mu \exp(\hat{a}_t) = \chi_\mu(\hat{a}_t).$$  \hspace{1cm} (3.13)

The first equality is the character of $\hat{a}_t$ as an element of $\mathfrak{h}$. This is expressed as a Weyl character in the second equality. We recall the latter’s definition:

$$\chi_\mu(\hat{a}_t) \equiv \sum_{\mu' \in \Omega_\mu} \exp \left( [\mu', \hat{a}_t] \right),$$  \hspace{1cm} (3.14)

where $\mu'$ are the weights in the weight system $\Omega_\mu$ of the highest weight $\mu$, which span a highest-weight representation of $G$. By the Weyl character formula, (3.14) can be written as a ratio of sums over the Weyl group $W$ of $G$:

$$\chi_\mu(\hat{a}_t) = \frac{D_{\mu + \rho}(\hat{a}_t)}{D_\mu(\hat{a}_t)} = \sum_{w \in W} \varepsilon(w) e^{(w(\mu), \hat{a}_t)}.$$  \hspace{1cm} (3.15)

Now, we act with $\hat{W}_\mu[\Sigma]$ on the $a_\phi = 0$ eigenstate $|0\rangle$, radially evolve it and compute the overlap with the coherent state $(A_z | \equiv e^{iu\tau_2^{-1}} | 0\rangle$. By using (3.8) we get

$$(A_z = iu\tau_2^{-1}|e^{-iHR}\hat{W}_\mu[\Sigma]|0\rangle) = \sum_{\mu' \in \Omega_\mu} (A_z = iu\tau_2^{-1}|e^{-iHR}|2\pi\mu'/k\rangle) = e^{-\frac{i\pi u}{2}} \text{Tr}|z\rangle \sum_{\mu' \in \Omega_\mu} \chi_{\mu', k}(u, \tau).$$  \hspace{1cm} (3.16)

The Wilson loop operator $\hat{W}_\mu[C_t]$ should compute the Weyl-Kac character when inserted into the path integral – as expected from a canonical quantization. Since $\hat{W}_\mu[\Sigma]$ was obtained by “blowing-up” $\hat{W}_\mu[C_t]$, we expect the amplitude $(A_z | e^{-iHR}\hat{W}_\mu[\Sigma]|0\rangle$ to give the same result, namely eq. (3.17). For this to be valid, the Weyl-Kac character needs to satisfy the identity

$$\sum_{\mu' \in \Omega_\mu} \chi_{\mu', k}(u, \tau) = \chi_{\mu, k}(u, \tau).$$  \hspace{1cm} (3.18)

Because the radial evolution is linear in the initial state, this identity holds if the corresponding identity is true for the Weyl character of the Lie algebra,

$$\sum_{\mu' \in \Omega_\mu} \chi_{\mu'} = \chi_\mu.$$  \hspace{1cm} (3.19)

This should be understood as an equality in terms of the Weyl character formula (3.15). Intuitively, this identity should hold due to the fact that all the weights $(\mu' + \rho)$ with $\mu' \in \Omega_\mu$, except for the highest weight $\mu$, pair up under simple Weyl transformations.

As an example, let us look at the $G = \text{SU}(2)$ case, in the spin-$J$ representation where $2J \in \mathbb{Z}_{\geq 0}$. In this case we have

$$\hat{W}_J[\Sigma]|0\rangle \equiv \text{Tr}_J \exp(\hat{a}_t)|0\rangle = \sum_{m=-J}^{J} \exp(-im\hat{a}_t)|0\rangle = \sum_{m=-J}^{J} |2\pi m/k\rangle.$$  \hspace{1cm} (3.20)
The amplitude is
\[
A_z = i u \tau^{-1} e^{-i H \tau} \hat{W}_J |\Sigma \rangle |0\rangle = e^{-\frac{k \tau}{2} \text{Tr} [u \tau^{-1} u]} \sum_{m=-J}^{J} \chi_{m,k}(u, \tau),
\] (3.21)
where here we used eq. (3.8). So the question is whether the following identity holds
\[
\sum_{m=-J}^{J} \chi_{m,k}(u, \tau) = \chi_{J,k}(u, \tau).
\] (3.22)
To prove this, note that (the numerator of) the \(\mathfrak{s}\mathfrak{u}(2)\) Weyl character trivially satisfies (3.19):
\[
\sum_{m=-J}^{J} \sin((2m + 1)2\pi u) = \sin((2J + 1)2\pi u),
\] (3.23)
The proof that this implies (3.22) is achieved by first writing down explicitly the Weyl-Kac character
\[
\chi_{J,k}(u, \tau) = \sum_{n \in \mathbb{Z}} q^{\frac{1}{4}(J+1/2+n(k+2))^2 - 1/4} \left( e^{4\pi i u(J+1/2+n(k+2))} - e^{-4\pi i u(J+1/2+n(k+2))} \right) \prod_{l=1}^{\infty} (1 - q^l)(1 - q^le^{4\pi i u})(1 - q^le^{-4\pi i u})
\] (3.24)
\[
= q^{-\frac{k}{4}} \sin(2\pi u) \prod_{l=1}^{\infty} (1 - q^l)(1 - q^le^{4\pi i u})(1 - q^le^{-4\pi i u})
\] (3.25)
\[
\times \sum_{n \in \mathbb{Z}} q^{\frac{1}{4}(2J+1+2n(k+2))^2} \sin((2J + 1 + 2n(k + 2))2\pi u),
\]
substituting it into (3.22), and comparing both sides for each \(|n| \in \mathbb{Z}_{\geq 0}\).
For the \(n = 0\) terms, note that, by differentiating (3.23) 2\(l\)-times with respect to \(u\), we get
\[
\frac{(-1)^l}{(2\pi)^{2l}} \frac{d^{2l}}{du^{2l}} (3.23),\quad l = 0, 1, \ldots \quad \Rightarrow \quad \sum_{m=-J}^{J} (2m + 1)^{2l} \sin((2m + 1)2\pi u) = (2J + 1)^{2l} \sin((2J + 1)2\pi u).
\] (3.26)
This implies
\[
\sum_{m=-J}^{J} e^{\alpha (2m+1)^2} \sin((2m + 1)2\pi u), \quad \alpha \in \mathbb{C}
\] (3.27)
\[
= \sum_{m=-J}^{J} \sum_{l=0}^{\infty} \frac{1}{l!} (2m + 1)^{2l} \sin((2m + 1)2\pi u) \quad \stackrel{(3.26)}{=} e^{\alpha (2J+1)^2} \sin((2J + 1)2\pi u).
\] (3.28)
Taking \(\alpha = 1/(4(k + 2))\), we prove the equality of the \(n = 0\) terms in (3.22).
Next, for the \(|n| \geq 1\) terms, we note that, for any \(b \in \mathbb{C}\),
\[
\sin((2m + 1 + 2b)2\pi u) + \sin((2m + 1 - 2b)2\pi u) = 4\sin((2m + 1)2\pi u)\sin(\pi/4 - b2\pi u)\sin(\pi/4 + b2\pi u),
\]
and so (3.23) implies
\[
\sum_{m=-J}^{J} \left[ \sin((2m + 1 + 2b)2\pi u) + \sin((2m + 1 - 2b)2\pi u) \right] = 4\sin((2J + 1)2\pi u)\sin(\pi/4 + b2\pi u) \quad \text{(3.31)}
\]
\[
= \sin((2J + 1 + 2b)2\pi u) + \sin((2J + 1 - 2b)2\pi u). \quad \text{(3.32)}
\]
Differentiating this identity 2l-times with respect to \(u\) gives
\[
\sum_{m=-J}^{J} \left[ (2m + 1 + 2b)^{2l} \sin((2m + 1 + 2b)2\pi u) + (2m + 1 - 2b)^{2l} \sin((2m + 1 - 2b)2\pi u) \right] \quad \text{(3.33)}
\]
\[
= (2J + 1 + 2b)^{2l} \sin((2J + 1 + 2b)2\pi u) + (2J + 1 - 2b)^{2l} \sin((2J + 1 - 2b)2\pi u),
\]
and thus for any \(b, \alpha \in \mathbb{C}\),
\[
\sum_{m=-J}^{J} \left[ e^{\alpha(2m+1+2b)^2} \sin((2m + 1 + 2b)2\pi u) + e^{\alpha(2m+1-2b)^2} \sin((2m + 1 - 2b)2\pi u) \right] \quad \text{(3.34)}
\]
\[
= e^{\alpha(2J+1+2b)^2} \sin((2J + 1 + 2b)2\pi u) + e^{\alpha(2J+1-2b)^2} \sin((2J + 1 - 2b)2\pi u).
\]
Taking \(\alpha = 1/(4(k+2))\) and \(b = |n|/(k+2)\), we prove the equality of the \(|n| \geq 1\) terms in (3.22).

### 3.2 Partition function as a gauge-invariant wave function

Here we proceed in the same way as in the Abelian case. A wave function transforms as
\[
A_z \rightarrow h A_z h^{-1} - h^{-1} \partial_z h^{-1}, \quad h : \hat{\Sigma} \rightarrow G \quad \text{(3.35)}
\]
\[
(U(h) \cdot \Psi)[A_z] \equiv \exp \left( + \frac{k}{2\pi} \int_{\Sigma} d^{2}x Tr [h^{-1} \partial_z h h^{-1} \partial_z h] - \frac{ik}{12\pi} \int_{\Sigma} d^{2}x Tr [(h^{-1}dh)^3] \right) \quad \text{(3.36)}
\]
\[
- \frac{k}{\pi} \int_{\Sigma} d^{2}x Tr [h^{-1} \partial_z h A_z] \right) \Psi[h^{\dagger} A_z].
\]
Since we consider a simply-connected group \(G\), the gauge group \(\mathcal{G}\) is connected. Similarly, starting from a wave function \(\Psi_0[A_z]\) that is not gauge-invariant, we can construct a gauge-invariant wave function by integrating over the gauge group:
\[
\Psi[A_z] \equiv \int_{\mathcal{G}} D'h (U(h) \cdot \Psi_0)[A_z]. \quad \text{(3.37)}
\]
Taking \(\Psi_0[A_z] = (A_z|a_0)\) as the seed wave function in (3.1) and after a quick calculation, one recovers the chiral Wess-Zumino-Witten path integral (3.6). In other words, radially evolving the wave function is equivalent to integrating over the gauge group, which results in a gauge-invariant wave function.

A The Riemann theta function

We define the genus-\(g\) Riemann theta function \(\theta^{[g]}_{[0]}(z, \Omega)\) with characteristics \((a, b)\) as in Mumford [18],

\[
\theta^{[g]}_{[0]}(z, \Omega) \equiv \sum_{n \in \mathbb{Z}^{g}} \exp \left[ \pi i (n + a) \Omega (n + a) + 2 \pi i (n + a)(z + b) \right], \quad z \in \mathbb{C}^{g}, \ a, b \in \mathbb{R}^{g}, \quad (A.1)
\]

with the quasi-periodicity

\[
\begin{aligned}
\theta^{[g]}_{[0]}(z + m, \Omega) &= \exp (2 \pi i a m) \theta^{[g]}_{[0]}(z, \Omega), \quad m \in \mathbb{Z}^{g}, \\
\theta^{[g]}_{[0]}(z + \Omega n, \Omega) &= \exp (-2 \pi i b n \Omega) \exp (-\pi i \Omega n - 2 \pi i n z) \theta^{[g]}_{[0]}(z, \Omega), \quad n \in \mathbb{Z}^{g}.
\end{aligned}
\]

(A.2)

Consider a compact, simple and simply-connected group \(G\). We identify the root space and the co-root space using the inner product \((\cdot, \cdot)\), for which we use the standard normalization such that the longest roots are of square-length two. We recall also the definition of the level-\(k\) theta function on the genus-one Riemann surface (the torus) given in [15],

\[
\theta_{\mu,k}(u, \tau) \equiv \sum_{\beta^{\vee} \in \Lambda^{R}} \exp \left( \pi i k \tau \left( \beta^{\vee} + \frac{\mu}{k}, \beta^{\vee} + \frac{\mu}{k} \right) + 2 \pi i k \left( u, \beta^{\vee} + \frac{\mu}{k} \right) \right). \quad (A.3)
\]

Here \(\Lambda^{R} \equiv \sum_{j=1}^{\text{rank}(g)} \mathbb{Z} \alpha_{j}^{\vee}\) is the co-root lattice of \(g\), where \(\alpha_{j}^{\vee}\) are the simple co-roots. \(u \in \Lambda^{R}\), and \(\mu\) is a weight. Since the Cartan matrix for a simple Lie algebra has integer entries, \((\alpha_{i}^{\vee}, \alpha_{j}^{\vee}) \in \mathbb{Z}\), the theta function (A.3) has the quasi-periodicity

\[
\begin{aligned}
\theta_{\mu,k}(u + m \alpha_{i}^{\vee}, \tau) &= \exp (2 \pi i m \alpha_{i}^{\vee}) \theta_{\mu,k}(u, \tau), \quad m, n \in \mathbb{Z}, \\
\theta_{\mu,k}(u + n \alpha_{i}^{\vee}, \tau) &= \exp (-\pi i \tau (n_{i} \alpha_{i}^{\vee}, n_{i} \alpha_{j}^{\vee}) - 2 \pi i (u, n_{i} \alpha_{i}^{\vee})) \theta_{\mu,k}(u, \tau).
\end{aligned}
\]

(A.4)

In particular, if \(\mu\) is an integral weight, i.e. \(\mu \equiv (\alpha_{i}^{\vee}, \mu) \in \mathbb{Z}\), then \(\theta_{\mu,k}(u + m \alpha_{i}^{\vee}, \tau) = \theta_{\mu,k}(u, \tau)\).

B Quadratic differentials

We summarize essential facts about quadratic differentials on a Riemann surface from Strebel [22] and Hubbard & Masur [27].

Consider a compact Riemann surface \(\Sigma\) of genus \(g\) and \(n\) punctures, endowed with a complex structure which defines a local complex coordinate denoted by \(z\). A (meromorphic) quadratic differential \(\varphi\) on \(\Sigma\) is a \((2,0)\)-meromorphic differential; it locally takes the form

\[
\varphi = h(z) dz \otimes dz \equiv h(z) dz^{2}, \quad (B.1)
\]

where \(h(z)\) is meromorphic, and under a holomorphic change of coordinate \(z \to \tilde{z}(z)\), it transforms by the chain rule as

\[
z \to \tilde{z}(z), \quad h(z) \to \tilde{h}(\tilde{z}) = \left( \frac{dz}{d\tilde{z}} \right)^{2} h(z), \quad \text{so that } \varphi = \tilde{h}(\tilde{z}) d\tilde{z}^{2} = h(z) dz^{2}. \quad (B.2)
\]
When $h(z)$ is holomorphic, then $\varphi$ is a **holomorphic quadratic differential**. On a closed genus-$g > 1$ Riemann surface without punctures, the complex dimension of the space of all holomorphic quadratic differentials is $(3g - 3)$, as a result of the Riemann-Roch theorem.

Quadratic differentials find applications in physics, especially in conformal field theory and string field theory (see e.g. [28–31]), because they provide a convenient foliation for a Riemann surface $\Sigma$. Given a meromorphic quadratic differential $\varphi$, a *horizontal trajectory* is a non-self-intersecting continuous loop on which $\varphi$ is real and positive, while a *vertical trajectory* is a non-self-intersecting continuous loop on which $\varphi$ is real and negative. Equivalently, on a local patch $U$ of $\Sigma$ with complex coordinate $z$, and a base point $p_0 \in U$, we can define a local natural complex coordinate $w$ on $p \in U$ by

$$
w(p) \equiv \int_{p_0}^{p} \sqrt{h(z)} \, dz, \quad \varphi = h(z) \, dz^2.
$$

Then, on a horizontal (vertical) trajectory, $w$ has constant imaginary (real) part. A *critical point* of a $\varphi$ meromorphic on $\Sigma$ is a zero or a pole of $\varphi$, while all other points on $\Sigma$ are called regular points. A *critical trajectory* is a horizontal trajectory that joins critical points. In general, a zero of order $n$ is the endpoint of some $(n + 2)$ critical trajectories.

A quadratic differential $\varphi$ defines a metric on $\Sigma$, which is locally given by

$$
ds^2 = |h(z)| \, dz d\bar{z} = \sqrt{h(z)} \sqrt{h^{*}(\bar{z})} \, dz \, d\bar{z},
$$

with the corresponding line element

$$
|d\!w| = \sqrt{|h(z)|} |dz|.
$$

Since $h(z)$ is holomorphic away from critical points, the metric (B.4) is flat away from critical points, while the curvature at a critical point is singular.

A *meromorphic* quadratic differential $\varphi$ on $\Sigma$ is called (Jenkins-)Strebel\(^5\) if it has “almost only” closed horizontal trajectories, i.e. if its non-closed horizontal trajectories cover a set of measure zero.

There are various existence and uniqueness theorems for quadratic differentials on a Riemann surface, with or without punctures. One of them is Theorem 21.1 of [22] which states:

**Theorem.** Consider a closed genus $g > 1$ Riemann surface $\Sigma$ without punctures. Let \( \{ \gamma_i \} (i = 1, \ldots, 3g - 3) \) be a system of non-self-intersecting continuous closed loop, which are homotopically non-trivial on $\Sigma$, mutually disjoint and belong to different homotopic classes. Also let $m_i = 1, \ldots, 3g - 3 > 0$. Then there exists a holomorphic Strebel differential $\varphi$ on $\Sigma$ that divides $\Sigma$ into cylinders, each of modulus $M_i = Km_i$, where $K$ is a positive constant independent of $i$.

For $g = 1$, i.e. the torus, a Strebel differential $\varphi$ obviously exists: $\varphi = dz^2$.

---

\(^5\)Some parts of the mathematical literature, e.g. Hubbard & Masur [27], further restrict a Strebel differential to be holomorphic.
