OBJECTIVE Improvements in imaging and surgical technological innovations have led to the increasing implementation of fetal surgical techniques. Open fetal surgery has demonstrated more favorable clinical outcomes in children born with open myelomeningocele (MMC) than those following postnatal repair. However, primarily because of maternal risks but also because of fetal risks, fetal surgery for MMC remains controversial. Here, the authors evaluated the contemporary management of MMC in the hope of identifying barriers and facilitators for neurosurgeons in providing fetal surgery for MMC.

METHODS An online survey was emailed to members of the Congress of Neurological Surgeons (CNS) and the International Society for Pediatric Neurosurgery (ISPN) in March 2019. The survey focused on 1) characteristics of the respondents, 2) the practice of counseling on and managing prenatally diagnosed MMC, and 3) barriers, facilitators, and expectations of fetal surgery for MMC. Reminders were sent to improve the response rate.

RESULTS A total of 446 respondents filled out the survey, most (59.2%) of whom specialized in pediatric neurosurgery. The respondents repaired an average of 9.6 MMC defects per year, regardless of technique. Regardless of the departments in which respondents were employed, 91.0% provided postnatal repair of MMC, 13.0% open fetal repair, and 4.9% fetoscopic repair. According to the surgeons, the most important objections to performing open fetal surgery were a lack of cases available to become proficient in the technique (33.8%), the risk of maternal complications (23.6%), and concern for fetal complications (15.2%). The most important facilitators according to advocates of prenatal closure are a decreased rate of shunt dependency (37.8%), a decreased rate of hindbrain herniation (27.0%), and an improved rate of motor function (18.9%). Of the respondents, only 16.9% agreed that open fetal surgery should be the standard of care.

CONCLUSIONS The survey results showed diversity in the management of patients with MMC. In addition, significant diversity remains regarding fetal surgery for MMC closure. Despite the apparent benefits of open fetal surgery in selected pregnancies, only a minority of centers and providers offer this technique. As a more technically demanding technique that requires multidisciplinary effort with less well-established long-term outcomes, fetoscopic surgery may face similar limited implementation, although the surgery may pose fewer maternal risks than open fetal surgery. Centralization of prenatal treatment to tertiary care referral centers, as well as the use of sophisticated training models, may help to augment the most commonly cited objection to the implementation of prenatal closure, which is the overall limited caseload.

KEYWORDS spina bifida; survey; fetal surgery; meningomyelocele
MyeLOMENgoCELE (MMC), characterized by extrusion of the spinal cord together with the meningeal membranes, is the most severe and common form of spina bifida. Standard treatment is closure of the MMC defect within 48 hours of birth to minimize infectious and traumatic risk to the tissue. Since publication of the first case of surgical closure of an MMC defect in 1892, only limited progress has been made in surgical repair with the primary goals of creating a watertight closure over the open neural placode. Patients born with MMC can face lifelong disabilities such as neurological deficits below the level of the defect, hydrocephalus, hindbrain herniation, scoliosis, tethering of the spinal cord, urinary and fecal incontinence, and sexual dysfunction.

Early in vivo studies suggested that prenatal intervention could prevent secondary insults to the neural placode and the development of hindbrain herniation or hydrocephalus due to persistent intrathecal CSF leakage. Further surgical innovations and improvements in instrumentation refined this technique and improved mortality and morbidity rates. Initially, fetal surgery served as an option to treat potentially lethal conditions such as congenital diaphragmatic hernia, improving early mortality rates. With increasing knowledge and experience, the indications for fetal surgery have broadened toward treating nonlethal diseases such as MMC. At the end of the last century, early case studies of fetal MMC repair showed promising results and eventually led to a randomized controlled trial published in 2011.

In the Management of Myelomeningocele Study (MOMS), women diagnosed with a fetus having MMC were randomized to undergo either open fetal surgery before 26 weeks of gestation or conventional postnatal surgical repair. This trial was stopped prematurely given the efficacy of prenatal surgery. Results showed that only 40% of the prenatal surgery group needed placement of a shunt versus 82% in the postnatal surgery group at 1 year. In addition, children with MMC in the prenatal surgery group were less likely to have hindbrain herniation and were more likely to have a better level of motor functioning and to walk independently. However, these promising fetal outcomes came at the expense of maternal morbidity with higher rates of preterm delivery and a higher risk of maternal complications such as placental abruption and choioamniotic membrane separation. Fetal surgery also carries risks for the fetus such as the need for transfusions and a lower birth weight. Furthermore, the MOMS had strict inclusion criteria, reflected by the fact that of the 183 who underwent randomization, only 183 underwent randomization.

Fetoscopic techniques were developed in the hopes of lowering maternal morbidity both in the current pregnancy and in future pregnancies. Developments and refinements have further improved fetoscopic techniques. Unlike open prenatal repair, fetoscopic surgery was less well received by the neurosurgical community because of the complexity of the procedure and less-established outcomes.

With the rise of fetal surgery and the increasing evidence of its risks and benefits in treating selected pregnancies with MMC, neurosurgeons may increasingly face ethical dilemmas, such as weighing maternal risks against potential fetal benefits. An expected paradigm shift in the treatment of MMC since publication of the MOMS results has led to an interest in knowing about the current management and application of fetal surgery by our colleagues. We aimed to identify the barriers and facilitators of fetal closure perceived by the neurosurgeons providing current techniques for MMC repair. Therefore, we conducted a survey on the management of MMC by neurosurgeons to evaluate the clinical practice worldwide.

Methods

Based on the literature, a first concept survey was developed. This survey was reviewed by two pediatric neurosurgeons experienced in treating MMC as well as a maternal-fetal medicine specialist before being finalized. The survey consists of 17 questions and can be divided into three sections: 1) characteristics of the respondents, such as subspecialization, tenure, and country of employment; 2) the practice of counseling on and managing MMC, such as the items discussed during counseling of parents, number of MMC defects closed yearly, and the availability of prenatal surgery to treat MMC; and 3) barriers, facilitators, and expectations of fetal surgery for MMC. The survey can be found in the Supplemental Material: Survey. The institutional review board waived the need for study approval as this research does not involve patients.

Members of the Congress of Neurological Surgeons (CNS) and the International Society for Pediatric Neurosurgery (ISPN) were approached by an email invitation containing a cover letter asking them to fill out a survey. The CNS was founded in 1951 and represents more than 9000 international members, who include residents, neurosurgeons, and medical students, among others. The ISPN consists of more than 350 pediatric neurosurgeons with the aim of improving the neurosurgical care of children. In March 2019 the survey was distributed by email, using SurveyMonkey. To increase the response rate, reminders were sent. By filling out a survey, respondents gave informed consent. Only responses from neurosurgeons and neurosurgery residents were included.

Data were analyzed using the IBM SPSS Statistics, version 21.0 for Windows (IBM Corp.). Descriptive statistics were used to present data in frequencies and percentages. Categorical data were analyzed using the chi-square test. A p value < 0.05 was considered to be statistically significant.

Results

Characteristics of the Respondents

A total of 448 respondents filled out the survey. Two responses were not from neurosurgeons or neurosurgery residents and were therefore excluded. Eighty-four percent of the respondents were from the CNS, while the remaining 16% were from the ISPN. Respondents were employed in a total of 58 countries, with the US (56.3%), Brazil (5.2%), and India (4.9%) having the most respondents (Fig. 1). Africa was the least represented (2.7%; Table 1).

Respondents had a mean clinical experience of 21.6 ± 12.9 years (mean ± standard deviation), with residents...
having a mean clinical experience of 5.5 years (Table 1). Most of the respondents had pediatric neurosurgery as their subspecialization (59.2%). Spine (29.6%) and neurooncology (28.3%) followed as the most frequent subspecializations.

Among the respondents, 81.0% treated patients with MMC. Neurosurgeons subspecialized in pediatric neurosurgery were more likely to treat patients with MMC (p < 0.001). Among neurosurgeons not subspecialized in pediatric neurosurgery, 54.8% treated patients with MMC. Neurosurgeons performing closure of MMC defects operated on a mean of 9.6 ± 17.9 patients annually.

Counseling and Management of MMC

Three-quarters (74.5%) of the neurosurgeons and 50% of the residents deemed themselves sufficiently informed to counsel parents (p = 0.008), and 72.2% of the respondents actually counsel potential parents with children suspected to have MMC. Of those neurosurgeons who deemed themselves insufficiently informed to counsel, 37.2% still counsel potential parents. Table 2 gives an overview of several items discussed by respondents during the counseling of potential parents. All items differed statistically significantly between pediatric and nonpediatric neurosurgeons. Surgical closure of the MMC defect, the need for CSF shunting, and the expected level of motor function were always discussed by 83.1%, 75.3% and 69.4% of respondents, respectively. Termination of the pregnancy and the option of fetal surgery were never discussed by 35.6% and 23.7% of the neurosurgeons, respectively.

TABLE 2. Items discussed during counseling by pediatric versus nonpediatric neurosurgeon respondents

| Item             | Pediatric Neurosurgeons | Nonpediatric Neurosurgeons | p Value |
|------------------|-------------------------|-----------------------------|---------|
| Orthopedic管理   | Always                  | 58.4%                       | 31.6%   | <0.001 |
|                  | Often                   | 22.9%                       | 18.0%   |
|                  | Sometimes               | 11.4%                       | 22.6%   |
|                  | Rarely                  | 4.5%                        | 6.8%    |
|                  | Never                   | 2.9%                        | 21.1%   |

Barriers, Facilitators, and Expectations of Fetal Surgery for MMC

When asked to rank the most important objections to providing open fetal surgery to treat MMC, 33.8% ranked “too few cases available to become proficient in the technique” as number one (Fig. 2). The risk of maternal complications and the risk of fetal complications were ranked second and third, respectively, by 23.6% and 15.2%. Costs and ethical concerns were ranked last by 23.4% and 15.2%, respectively. Pediatric neurosurgeons were less likely than nonpediatric neurosurgeons (p = 0.002) to involve pediatrics.

Discussion

This study gives an overview of the current management of MMC and opinions on fetal surgery by neurosurgeons worldwide. Open fetal surgery (13.0%) and especially fetoscopic surgery (4.9%) are provided by only a minority of the centers in which the respondents are employed. Despite the well-documented decreased rates of shunt dependency and hindbrain herniation and improved rate of motor function in strictly selected pregnancies, only 16.9% of respondents agreed that open fetal surgery should be the standard of care. The most important objections to the procedure are a limited caseload available to become proficient in the technique, the risk of maternal complications, and the risk of fetal complications. The bind in the trade-off between maternal health and the health and quality of life of patients with MMC is illustrative.
TABLE 3. Disciplines involved in the management of MMC

| Discipline             | Pediatric Neurosurgeons | Nonpediatric Neurosurgeons | p Value |
|------------------------|-------------------------|----------------------------|---------|
| Pediatrics             |                         |                            | 0.002   |
| Always                 | 55.6%                   | 71.3%                      |         |

trated by the equally divided opinions regarding the statement that “denying potential improvement in the quality of life of MMC patients by not offering fetal surgery is acceptable.”

Comparison With Other Studies

When the results of the MOMS were published in 2011, a paradigm shift was expected. However, such a shift was not reflected in our results: 23.7% of respondents never discuss the option of fetal surgery during counseling, and only 16.9% agree that open fetal surgery should be standard care. Moreover, only 13.0% of respondents offer open fetal surgery, while 4.9% offer fetoscopic surgery. An explanation for these low rates may be the generalizability of the MOMS, which included pregnancies carrying fetuses with MMC based on strict inclusion criteria. Results of fetal surgery for other pregnancies are less well-documented and warrant prospective studies. Another explanation may be the maternal comorbidity and the risk for future pregnancies. In the literature, a maternal complication rate of 6.2% for fetoscopic surgery and a rate of 20.9% for open fetal surgery have been reported. When taking into account only serious maternal complications such as those requiring ICU care or surgical intervention, risk rates of 1.7% and 4.5% have been reported for fetoscopic and open procedures, respectively.

Our results showed that 62.6% of the respondents assume that open fetal surgery carries a higher risk of neonatal death. Moreover, almost 40% wrongly assume a higher maternal mortality rate. These data may imply that a factor contributing to the nonoccurrence of the paradigm shift may be a lack of knowledge—on the one hand, a lack of knowledge because the outcomes reported in the literature may not be known among respondents, and on the other hand, because the results reported in the literature (e.g., MOMS) may not be generalizable to all pregnancies carrying fetuses with MMC.

Previous studies have shown that fetal surgery, especially fetoscopic surgery, is technically demanding and requires dedicated training. This may be reflected by the fact that only 4.9% of the departments surveyed provide fetoscopic surgery. A number of studies have been conduct-

### TABLE 3. Disciplines involved in the management of MMC

| Discipline       | Pediatric Neurosurgeons | Nonpediatric Neurosurgeons | p Value |
|------------------|--------------------------|-----------------------------|---------|
| Urology          |                          |                             | NS      |
| Always           | 33.2%                    | 32.9%                       |         |
| Often            | 13.2%                    | 16.5%                       |         |
| Sometimes        | 12.3%                    | 19.0%                       |         |
| Rarely           | 20.5%                    | 8.9%                        |         |
| Never            | 20.9%                    | 22.8%                       |         |

NS = not significant.

![FIG. 2. The most important objections to providing open fetal surgery for the treatment of MMC. The y-axis represents the percentage of respondents. The x-axis represents the rank chosen for each objection.](image-url)
ed to assess the relationship between hospital and surgeon volume and surgical mortality and morbidity.\textsuperscript{7,24} These studies have shown that a high surgeon volume results in superior outcomes for patients. Paradoxically, the majority of our respondents also agree that performing only one case of fetal surgery per month is acceptable, which mirrors the respondents’ current practice of approximately 9.6 MMC repairs per year.

In light of the high case volume, the Maternal-Fetal Management Task Force released a position statement in which minimum criteria are recommended to ensure optimal maternal and fetal outcomes.\textsuperscript{10} In this statement, an initial experience of 5 cases is required, as is an adequate annual volume of cases to maintain proficiency. The exact number of cases meant by “adequate” is subject to debate, however. A recent meta-analysis on the learning curves of fetal surgery estimated that competence for standard hysterotomy is reached after 35 cases and that competence for minimally invasive procedures is reached after 56 cases.\textsuperscript{20}

In this context, a smaller number of centers dedicated to fetal surgery, in which surgeons perform larger volumes of cases, is more desirable than a more disseminated offering of fetal surgery. A remedy toward achieving and maintaining proficiency may be adequate training models.\textsuperscript{26} Assisted nowadays by 3D-printed models, it is possible to create case-specific models to prepare for complex procedures such as fetoscopic surgery.

TABLE 4. Expectations regarding the risks of maternal and fetal complications of three techniques to close MMCs

| Complication & Procedure | Level of Risk |
|--------------------------|--------------|
|                          | Most | Moderate | Least    |
| Maternal complication    |      |          |         |
| Postnatal surgery        | 2.7% | 4.8%     | 92.5%   |
| Open fetal surgery       | 89.2%| 8.8%     | 2.0%    |
| Fetoscopic surgery       | 79.9%| 13.6%    | 9.5%    |
| Fetal complication       |      |          |         |
| Postnatal surgery        | 16.3%| 21.4%    | 62.2%   |
| Open fetal surgery       | 70.6%| 19.9%    | 9.5%    |
| Fetoscopic surgery       | 66.8%| 22.7%    | 10.5%   |

TABLE 5. Respondent knowledge about open prenatal surgery performed before 26 weeks of gestation

| Statement                                                | Respondent Answer |
|----------------------------------------------------------|------------------|
| Fetal surgery leads to a higher risk of maternal death   | 39.4%            |
|                                                           | 60.6%            |
| Fetal surgery leads to a higher risk of maternal         | 90.6%            |
| complications such as placental abruption                | 9.4%             |
| Fetal surgery leads to a higher risk of neonatal death    | 62.6%            |
|                                                           | 37.4%            |
| Fetal surgery halves the neonatal CSF shunt rate         | 68.2%            |
|                                                           | 31.8%            |
| Children who underwent prenatal surgery have a lower     | 11.5%            |
| level of mental & motor function                         | 88.5%            |

Answers in boldface type indicate results of the MOMS.
Another debatable subject is the position of fetoscopic surgery. In a recent meta-analysis, outcomes of fetoscopic and open repair of MMC defects, published after MOMS, were analyzed and compared.

A total of 11 studies were included, 4 retrospective and 7 prospective, comprising 436 patients. Fetoscopic MMC repair (percutaneous or laparotomy access combined) was associated with a lower rate of uterine dehiscence; however, this came with a higher rate of dehiscence or CSF leakage of the MMC defect, requiring postnatal revision. There were no between-group differences regarding fetal and postnatal mortality, rate of shunt placement, reversal of hindbrain herniation, motor response, gestational age before birth, chorioamnioniotic membrane separation, or placental abruption. Expectations of our respondents were similar with 89.2% expecting open fetal surgery to have the highest risk for maternal complications. Authors of another meta-analysis concluded similarly, suggesting that before performing a randomized study, endoscopic techniques should be improved first.

To date, no randomized controlled studies have compared the two techniques of fetoscopic and open postnatal repair. Only a minority of our respondents, 21.9% (strongly) believe it is acceptable to provide prenatal fetoscopic surgery without performing a randomized controlled trial. Fetoscopic surgery faces multiple barriers to implementation, as indicated by the reluctance of neurosurgeons to offer open fetal repair for MMC with only 13.0% of centers in our respondent pool offering the procedure.

### Study Strengths and Limitations

Some limitations of this study must be acknowledged. First, the response rate could be a limitation. The survey was mailed to 7671 functional email addresses of CNS members. Three hundred seventy-four responses were from CNS members leading to an estimated response rate

QOL = quality of life; RCT = randomized controlled trial.
of 4.9%. Of note, some of the email addresses may have belonged to medical students or other allied health professionals who may not have been eligible to fill out the survey. The importance of the response rate when judging the quality of cross-sectional research, however, is subject to debate.\textsuperscript{7,21} Given that 446 neurosurgeons with variable tenure and representing 58 countries responded to our survey, we expect a limited risk of nonresponse bias. However, we assume that MMC-dedicated centers, which also offer fetal surgery, may have been more inclined to respond. Another limitation may be the unfamiliarity of the respondents with either the care of patients with MMC or prenatal surgery. However, 81.0% stated that they treat respondents with either the care of patients with MMC or prenatal surgery. However, 81.0% stated that they treat patients with MMC and 91.0% worked at a department where either postnatal or prenatal surgery is provided.

Conclusions

The survey results show the diversity in the management of patients with MMC. In addition, significant diversity remains regarding fetal surgery for MMC closure. Despite the apparent benefits of open fetal surgery in selected pregnancies, only a minority of centers and providers offer this technique. As a more technically demanding technique that requires multidisciplinary effort with less-well-established long-term outcomes, fetoscopic surgery may face similar limited implementation, although the surgery may pose fewer maternal risks than open fetal surgery. Centralization of prenatal treatment to tertiary care referrals centers, as well as the use of sophisticated training models, may help to augment the most commonly cited objection to the implementation of prenatal closure, which is the overall limited caseload.

Acknowledgments

We would like to thank all respondents for sharing their opinions and clinical management with us. These include Frank Van Calenbergh, Vaverka Miroslav, Salvatore Chibbaro, Micyn Mieunovic, Erwin Cornips, Bernt Due-Tønnessen, Bruno Lourenço Costa, Horia Ples, José Hinojosa, John Goedden, Tony Magana, Seraj S. Ajaj, Olufemi Idowu, Abubakr Darrag Salim Ahmed, Scott A. S银行, David Cech, Richard P. Moser, J. Paul Muizelaar, Curtis J. Rozzelle, Jesse Winer, Jodi L. Smith, William E.
