FUNCTIONAL CHARACTERIZATION OF SYNTHETIC
LEUKOTRIENE B AND ITS STEREOCHEMICAL ISOMERS*

Of the several possible double-bond stereoisomers of 5S,12R-dihydroxy-6,8,10,14-
eicosatetraenoic acid (5,12-di-HETE), based on physical measurements, one specific
compound (Fig. 1) (1-3) has been preliminarily reported to correspond to the
biologically generated neutrophil chemotactic factor, leukotriene B (LTB) (4, 5).
Previous studies (4, 6) had suggested the presence of one cis and two trans ethylene
bonds in its triene portion. We report the comparison of six synthetic stereoisomers of
unambiguously defined geometry with natural LTB, using chemotactic assays in vitro
and in vivo and spasmodic activity.

Materials and Methods

Preparation of Natural LTB from Human Neutrophils. Neutrophils isolated from venous blood of
normal subjects (5, 6) were incubated for 30 min at 37°C at a concentration of 5 × 10^7 cells/ml
in Hanks' balanced salt solution containing 0.02 M Tris-HCl, pH 8, 10 μM indomethacin, 5
μM calcium ionophore A23187, and 0.5 mg/ml of arachidonate. LTB and the monohy-
droxyeicosatetraenoic acids (mono-HETE) were extracted and resolved from both the residual
arachidonic acid and more polar products by silicic acid column chromatography (4, 5), and
LTB was purified by reverse-phase high performance liquid chromatography on a C18 ODS
column (UltraspHERE; Altex Scientific, Inc., subsidiary of Beckman Instruments, Inc., Berkeley,
Calif.) that was developed isocratically at a flow rate of 1 ml/min with methanol:water:glacial
acetic acid (78:22:0.01, vol/vol) (5). The purified LTB contained <1% of other mono- and di-
HETE, as assessed by gas chromatography (6).

Synthesis of 5,12-di-HETE Stereoisomers, Leukotriene C (LTC), and Leukotriene D (LTD). 5S,12R-
dihydroxy-6,14-cis,8,10-trans-eicosatetraenoic acid was synthesized, as previously described (1,
3), by two independent methods that produced the same substance. 5S,12R- and 5S,12S-6,8,10-
trans,14-cis di-HETE and 5S,12R-6,8-trans-10,14-cis di-HETE (2) were also prepared as outlined
previously. In the case of the C-12 diastereomers of the racemic 6,10-trans,8-cis di-HETE, the
racemate having the longer elution time was shown by independent synthesis to be 5S,12R and
also its enantiomer, using a reverse phase C18 column with 7:3 methanol:water for elution; the
(±)-5S,12S diastereomer eluted earlier in this chromatographic system (2). LTC and LTD were
prepared as previously described (7, 8).

In Vitro and In Vivo Assessment of Human Neutrophil Migration. Chemotaxis of human neutrophils
of >96% purity was assayed by a modification of the Boyden technique in chambers with a 0.2-
ml blind-end stimulus compartment (Neuroprobe, Inc., Bethesda, Md.) and filters with 3-μm

pores (Sartorius; Beckman Instruments, Inc., Science Essentials Co., Mountainside, N. J.), with the period of migration at 37°C reduced from that of previous studies (5, 6) to 45 min. The chemotactic responses were assessed in duplicate and expressed as net neutrophils per high power field (hpf) after subtraction of the background level of migration in the absence of a stimulus.

In three separate experiments, 13–16 cutaneous sites on the anterior thorax of an anesthetized rhesus monkey were each injected i.d. with 0.1 ml of phosphate-buffered saline/2% ethanol, pH 7.4, alone, or containing LTC, LTD, natural LTB, or a synthetic 5,12-di-HETE isomer. 4 h later, the monkey was again anesthetized, and a 4-mm punch biopsy was obtained from each injection site. Each specimen was fixed in Karnovsky's mixture and the Epon-embedded tissue was cut to a thickness of 1 μm, as previously described (9). Tissue sections were stained with Giemsa's reagent and examined with a Leitz Dialux 20 microscope (Marcon Instruments, Norwood, Mass.) at magnifications up to ×1,000. Neutrophil infiltrates per total biopsy section were graded semiquantitatively from examination of ~40 hpf as 0 (<5 cells), 1+ (5–20 cells), 2+ (21–100 cells), and 3+ (>100 cells).

**Results**

**In Vitro Neutrophil Migration.** The maximum chemotactic response to natural LTB (Table I) was comparable to that evoked by a 1:100 dilution of a standard preparation of fragments of the fifth component of human complement (C5) (59.8 ± 2.9) (6). Of the four synthetic stereoisomers of 5,12-di-HETE having one cis ethylenic bond in the conjugated triene portion of the molecule, only the 6-cis-8,10-trans compound (Fig. 1)—designated here as c,t,t, to indicate configurations of the 6,8, and 10 triene linkages, respectively—elicited a response comparable to that elicited by natural LTB, i.e., detectable at 0.3 ng/ml (10^-9 M) and maximum at 3–10 ng/ml (1–3 × 10^-8 M). With this abbreviated (45 min) incubation period for the chemotactic assay, neither of the two racemic mixtures of the 6-trans,8-cis,10-trans (t,c,t) compounds, nor the 6,8-trans-10-cis (t,t,c) compound elicited a reproducible net neutrophil chemotactic response at 10^-8 M, and, at concentrations up to 10^-6 M, none evoked a maximum response similar in magnitude to that elicited by natural LTB or the c,t,t compound (synthetic LTB). Within the assessed range of concentrations, the maximum effects of 5S,12S-t,c,t and its enantiomer and the t,t,c compound were elicited at 300 ng/ml (10^-6 M) and 100 ng/ml (3 × 10^-7 M), respectively, and were comparable in magnitude to the responses evoked by both natural and synthetic (c,t,t) LTB at 1 ng/ml (3 × 10^-9 M). The pure 5S,12S-dihydroxy-6,10-trans,8,14-cis-eicosatetraenoic acid synthesized by a different technique1 was no more active than the racemic mixture. The two all-trans (t,t,t) C-12 diastereomers of 5S,12-di-HETE were each even less potent, with 5S,12R t,t,t being the least active (Table I). In two separate experiments (data not shown) the racemic 5S,12R-/5R,12S-t,c,t mixture was 3- to 10-fold less active over a 2.5 log dose range than was the 5S,12S-/5R,12R-racemate of the same olefinic bond stereoisomer. The unnatural stereoisomeric analogues were not

only two orders of magnitude less potent than synthetic (c,t,t) LTB, but also exhibited a flatter dose-response curve that extended over two orders of magnitude and failed to achieve a maximum response equal to that observed with natural and synthetic (c,t,t) LTB.

In Vivo Cutaneous Response. In three experiments carried out to compare the histologic effects of five of the six synthetic 5,12-di-HETE, excluding 5S,12R-5R,12S-t,c,t, at 100 ng/site, only c,t,t provoked an infiltrative response by neutrophils at 4 h (2-3+), as did natural LTB (3+). Both natural LTB and synthetic (c,t,t) LTB also provoked modest (1-2+) neutrophil infiltration at 10 ng intradermal doses, in contrast to the other assessed synthetic isomers of 5,12-di-HETE, at 10 and 100 ng/site, and LTC and LTD, at up to 500 ng/site, which were inactive.

Nonvascular Smooth Muscle Spasmogenic Effects. The guinea pig pulmonary parenchymal strips responded to natural or synthetic (c,t,t) LTB in a dose-response fashion beginning at 3 × 10⁻¹⁰ M and reaching 25% of that response elicited by 10⁻⁴ M histamine (EC25) at 3 × 10⁻⁸ M; LTC and LTD achieved the same EC25 with 4 × 10⁻¹⁰ M and 2 × 10⁻¹¹ M, respectively. None of the other synthetic 5,12-di-HETE analogues induced a contraction >5% of the 10⁻⁴ M histamine response at concentrations up to 3 × 10⁻⁹ M. Neither natural nor synthetic (c,t,t) LTB provoked a response on the guinea pig tracheal spirals at 2 × 10⁻⁷ M; relative to the contraction elicited...
by 10^{-4} \text{M} \text{histamine}, the EC_{25} for LTD on this tissue was 3 \times 10^{-8} \text{M}. The ileum, which responds to 2 \times 10^{-10} \text{M} \text{LTD} with a contraction equal to that elicited by 4 \times 10^{-8} \text{M} \text{histamine}, failed to respond to 2 \times 10^{-6} \text{M} \text{synthetic (c,t,t) LTB}. 

Discussion

LTB, the most potent known lipid chemotactic factor for the in vitro attraction of neutrophils (5), is structurally a 5S,12R-di-HETE, with one of its three conjugated ethylenic bonds in the cis arrangement and the other two in the trans (1–5). Direct comparison of natural LTB and synthetic stereoisomers meeting these structural requirements demonstrated that only the 5S,12R-dihydroxy-6,14-cis,8,10-trans eicosatetraenoic acid (Fig. 1), c,t,t, has neutrophil chemotactic activity comparable to that of the natural product. Specifically, for both natural LTB and synthetic (c,t,t) LTB, a threshold effect was appreciable at 0.3 ng/ml, one-half maximum effect at 1 ng/ml, and maximum effect at 3–10 ng/ml (Table I). In contrast, the concentrations of the related synthetic t,c,t and t,t,c compounds eliciting a neutrophil response comparable to the one-half maximum LTB effect were each 100 ng/ml; thus, these isomers are two orders of magnitude less active than the natural product and approximately as equiactive as 5-L-hydroxy-6,8,11,14-eicosatetraenoic acid (5-HETE) (12). As previously recognized (6, 13), each of the t,t,t C-12 diastereomers was even less active.

Comparisons of natural LTB with five of the synthetic 5,12-di-HETE for local in vivo chemotactic effects in the skin of a rhesus monkey and for nonvascular smooth muscle spasmogenic effects in vitro on guinea pig pulmonary parenchymal strips were also discriminating. In each assay, natural LTB and synthetic (c,t,t) LTB produced an approximately equivalent dose-related response, whereas the other four analogues had little to no effect within the same concentration range. As natural LTB and synthetic 5S,12R-dihydroxy-6,14-cis,8,10-trans-eicosatetraenoic acid appear to be functionally identical in three assays, their identity is strongly implied. In both the rhesus monkey and the human (14), LTB is by itself capable of inducing a local cutaneous neutrophil infiltrate at 4 h and in the human appears to give an initial wheal and flare.

Natural and synthetic (c,t,t) LTB, like LTC and LTD, demonstrated a preferential action on guinea pig pulmonary parenchymal strips as opposed to tracheal spirals. However, the EC_{25} (relative to the effect of 10^{-4} \text{M} \text{histamine}) for LTB is 1.9 and 3.2 logs higher than for LTC and LTD, respectively, and this effect of LTB is apparently expressed indirectly through one or more cyclooxygenase products generated from the LTB-stimulated strip (15).

The structural basis for the 100-fold increased efficacy of LTB above that of 5-HETE in eliciting chemotaxis of human neutrophils must relate to the omega portion of the molecule, from C-6 to C-20, in which LTB incorporates a second hydroxyl group at C-12 and three, rather than two, ethylenic bonds in conjugation. The most stable conformation of LTB is expected to involve a coplanar arrangement of carbons 5–12 with s-trans stereochemistry about the 7,8- and 9,10- bonds, as shown in Fig. 1. This conformation is also indicated by an analysis of the 270 and 500 MHz proton magnetic resonance spectrum of the diacetate methylester of the c,t,t compound (P. B. Hopkins, unpublished data). It is likely that the remaining carbons prefer a maximally staggered, extended conformation. If it is assumed that this
preferred molecular geometry is involved in binding to the recognition site and that the geometrical preferences for other 5,12-di-HETE are similar (e.g., coplanar C-5 to C-12 s-trans triene system), it seems clear from tracing paper overlays of the molecular structures that the t,c,t structure is the closest match to c,t,t LTB and the t,t,t structure is the poorest one, with t,t,c being intermediate. This order is consistent with their relative chemotactic efficacies (Table I). We conclude that the structure of natural LTB is 5S,12R-dihydroxy-6,14-cis,8,10-trans-eicosatetraenoic acid (Fig. 1) and that its chemotactic potency is critically dependent upon the stereochemistry within the C-1 to C-12 domain.

Summary

Leukotriene B (LTB), a potent lipid chemotactic factor for neutrophils, is 5S,12R-dihydroxy-6,14-cis,8,10-trans-eicosatetraenoic acid (Fig. 1), based upon direct comparison of natural LTB with synthetic 5S,12R-dihydroxy-6,8,10,14-eicosatetraenoic acid (5,12-di-HETE) stereoisomers in three biological assays. Of the six synthetic stereoisomers evaluated, only the 5S,12R,6,14-cis,8,10-tram compound had chemotactic potency for human neutrophils in vitro that was comparable to that of natural LTB, with a concentration of $3 \times 10^{-9}$ M eliciting a one-half maximum response. In contrast, the racemic mixture of 5R,12R- and 5S,12S-6,10-trans,8,14-cis, the racemic mixture of 5S,12R- and 5R,12S-6,10-trans,8,14-cis, the 5S,12R-6,8-trans,10,14-cis, the 5S,12R-6,8,10-trans,14-cis, and the 5S,12S-6,8,10-trans,14-cis stereoisomers required concentrations of $3 \times 10^{-7}$ to $1 \times 10^{-6}$ M to elicit comparable responses. Only natural LTB and its synthetic counterpart elicited a local neutrophil infiltration when injected into the skin of the rhesus monkey at 10 ng and 100 ng per site. Natural and synthetic LTB at a concentration of $3 \times 10^{-8}$ M each provoked an EC25 contractile response of guinea pig pulmonary parenchymal strips in vitro, whereas the other four tested stereoisomers of 5,12-di-HETE were inactive at this concentration. Structure-function analyses suggest that the neutrophil chemotactic activity depends critically upon the C-1 to C-12 domain, including the stereochemistry of the 6-, 8-, and 10-olefinic bonds and the presence of both hydroxyl groups.

Received for publication 8 June 1981 and in revised form 22 July 1981.
