We show that certain three-dimensional Hořava-Lifshitz gravity theories can be written as Chern-Simons gauge theories on various non-relativistic algebras. The algebras are specific extensions of the Bargmann, Newton–Hooke and Schrödinger algebra each of which has the Galilean algebra as a subalgebra. To show this we employ the fact that Hořava-Lifshitz gravity corresponds to dynamical Newton–Cartan geometry. In particular, the extended Bargmann (Newton–Hooke) Chern–Simons theory corresponds to projectable Hořava-Lifshitz gravity with a local $U(1)$ gauge symmetry without (with) a cosmological constant. Moreover we identify an extended Schrödinger algebra containing 3 extra generators that are central with respect to the subalgebra of Galilean boosts, momenta and rotations, for which the Chern–Simons theory gives rise to a novel version of non-projectable conformal Hořava-Lifshitz gravity that we refer to as Schrödinger gravity. This theory has a $z = 2$ Lifshitz geometry as a vacuum solution and thus provides a new framework to study Lifshitz holography.

I. INTRODUCTION

The local equivalence of three-dimensional Einstein gravity (with or without a cosmological constant) in terms of a Chern-Simons gauge theory [1, 2] has been of crucial importance in order to gain insights into the classical and quantum properties of the theory, along with holographic dualities to two-dimensional CFTs. Three-dimensional (relativistic) gravity thus plays a special role due to its simplicity, having no propagating degrees of freedom, yet being non-trivial enough to allow for black holes and numerous other interesting features.

Recently non-relativistic geometry has gained considerable interest, in part due to their appearance in non-AdS holography [3–6], their relevance in condensed matter setups such as the fractional quantum Hall effect [7, 8] and other fluid/field-theoretic applications [6, 9–12]. Moreover these geometries lead to interesting theories of non-relativistic gravity, beyond Newtonian gravity as embodied in the original formulation of Cartan. In particular, a novel generalization of Newton-Cartan geometry with torsion was first observed in [3] and it was subsequently shown in [13] that making this geometry dynamical leads to the known versions of Hořava-Lifshitz gravity constructed in [14–16]. Interesting supersymmetric extensions of Newton-Cartan gravity have been considered as well [17–19]. All this begs the question whether in three dimensions such non-relativistic gravity theories are related to Chern-Simons (CS) theories, in parallel to the relativistic case.

The generalization of the CS formulation to non-relativistic Galilean gravity was initiated in the pioneering work [20], in which the CS gauge field takes value in a Galilean algebra with two central extensions (the extended Bargmann algebra), replacing the Poincaré algebra of the relativistic setting. We will show in this paper that this vielbein formulation is equivalent to three-dimensional torsionless Newton-Cartan (NC) gravity [13], which in turn is the 3-dimensional $U(1)$-invariant projectable Hořava–Lifshitz gravity of [16].\footnote{The topological nature of this theory was also discussed in [16].} By going to an extended Newton-Hooke algebra, we furthermore show that a cosmological constant can be added to the theory. Moreover, by constructing a $z = 2$ Schrödinger algebra with 3 extra generators, that are central with respect to the subalgebra of Galilean boosts, momenta and rotations, we obtain a novel action for conformal non-projectable Hořava–Lifshitz gravity. The latter theory corresponds to a new version of dynamical twistless torsional Newton-Cartan geometry which we call Schrödinger gravity.

The CS formulation based on the extended Bargmann algebra can be viewed as the non-relativistic counterpart of 3-dimensional Einstein gravity without a cosmological constant. Adding a cosmological constant via the Newton–Hooke algebra does not have the same effect as in the relativistic case. In particular the theory is still...
described by projectable Hořava–Lifshitz (HL) gravity. It will be shown that the cosmological constant leads to time dependent geometries.

In order to find the counterpart of AdS$_3$ gravity we need to find a CS theory that is equivalent to non-projectable HL gravity. This is provided by considering the extended Schrödinger algebra in 2+1 dimensions that allows for a CS theory corresponding to twistless torsional Newton-Cartan (TTNC) gravity, or what is the same non-projectable HL gravity, with $z = 2$ scaling symmetry. We show that this theory of Schrödinger gravity admits $z = 2$ Lifshitz geometries and thus provides a new framework to study Lifshitz holography.

This letter is organized as follows. In section II we discuss the basic properties of the three Lie algebras on which the CS actions are based, namely the extensions of the Bargmann, Newton–Hooke and Schrödinger algebras that admit a non-degenerate metric. In section III we construct the most general CS actions compatible with these symmetries. This includes terms that are the non-relativistic counterpart of the Lorentz CS term that can be added to the Einstein–Hilbert action in 3 dimensions. We continue in section IV to rewrite the CS actions based on the Bargmann and Newton–Hooke algebras in the metric formulation of Newton–Cartan geometry showing that the resulting theory is a known version of projectable HL gravity. In this section we also discuss the local properties of the solutions to the flatness conditions. Finally in section V we show that the CS theory based on the extended Schrödinger algebra is equivalent to a novel version of TTNC/ non-projectable HL gravity. In that section we also show that the theory admits $z = 2$ Lifshitz solutions. We conclude with a discussion and outlook in section VI.

II. NON-RELATIVISTIC LIE ALGEBRAS WITH NON-DEGENERATE METRICS

Non-relativistic symmetry algebras are typically non-semisimple Lie algebras, containing the Galilean algebra as a subalgebra, which consists (in 2+1 dimensions) of the generators $J$ (rotation), $P_a$ (translations, $a = 1, 2$), $G_a$ (Galilean boosts) and $H$ (Hamiltonian). In order to write down a Chern–Simons theory one needs a non-degenerate symmetric bilinear form (metric) on the Lie algebra that serves to define the trace in the Chern–Simons action:

$$L_{\text{CS}} = \text{Tr} \left( A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right).$$

For a non-semisimple Lie algebra the existence of such a bilinear form is a non-trivial requirement, and in case of the Galilean algebra with non-zero commutators

$$[J, P_a] = \epsilon_{ab} P_b, \quad [J, G_a] = \epsilon_{ab} G_b, \quad [H, G_a] = P_a,$$

it necessitates the addition of central elements. While in any dimension the Galilean algebra can be centrally extended to the Bargmann algebra using the mass generator $N$ satisfying

$$[P_a, G_b] = N \delta_{ab},$$

in 2+1 space-time it is possible to add three further central elements $S, Y$ and $Z$ as follows:

$$[G_a, G_b] = S \epsilon_{ab}, \quad [P_a, P_b] = Z \epsilon_{ab}, \quad [P_a, G_b] = N \delta_{ab} - Y \epsilon_{ab}.\quad (4)$$

These play an important role in obtaining non-degenerate metrics on various non-relativistic symmetry algebras such as the Bargmann, Newton–Hooke and Schrödinger algebras. In the following, we denote by $B(x, y)$ the bilinear form where $x$ and $y$ are elements of the Lie algebra. Symmetry requires that $B(x, y) = B(y, x)$ and invariance under the action of the algebra corresponds to $B([x, z], y) + B(x, [z, y]) = 0$ for all $x, z, y$.\footnote{In the case of the Galilei algebra one cannot add the $Y$ generator as a central extension because there is no non-trivial cohomology associated with it as follows from the results of [21, 22]. Here we will never use $Y$ in the context of the Galilei algebra but only in the larger Schrödinger algebra. We thank Joaquim Gomis for pointing this out to us.}

A. Extended Bargmann algebra

If we add the central element $S$ in (4) (but not $Y$ and $Z$) to the Bargmann algebra (2), (3) the resulting non-semisimple Lie algebra is a semi-direct sum of the normal subalgebra $H, P_a, N$ with the Nappi–Witten algebra \cite{23} consisting of $J, G_a, S$ (which is a central extension of the 2-dimensional Euclidean algebra). This algebra was used in the Chern–Simons theory (CS) of \cite{20} and corresponds, as shown below, to a 3D projectable Hořava–Lifshitz gravity theory. The possible non-trivial values of $B(x, y)$ for the centrally extended Bargmann algebra are given by

$$B(H, S) = -B(J, N) = c_1, \quad B(P_a, G_b) = c_1 \epsilon_{ab},$$

$$B(G_a, G_b) = c_2 \delta_{ab}, \quad B(J, S) = c_2,$$

$$B(J, J) = c_3, \quad B(H, J) = c_4, \quad B(H, H) = c_5, \quad (5)$$

with $c_i$ arbitrary constants and with $c_1 \neq 0$ for the matrix to be non-degenerate. If we remove the central element $S$ from the algebra the bilinear form becomes degenerate.
B. Extended Newton–Hooke algebra

There exists a deformation of the Bargmann algebra called the Newton–Hooke algebra. Its nonzero commutators are those of (2), (3) plus \([H, P_a] = -\Lambda_c G_a\). There exists an extension of this algebra involving the \(S\) generator where the central element appears

\[
[G_a, G_b] = S_{ab}, \quad [H, P_a] = -\Lambda_c G_a, \\
[P_a, P_b] = \Lambda_c S_{ab}.
\] (6)

This extended Newton–Hooke algebra, which reduces to the extended Bargmann algebra for \(\Lambda_c = 0\), was studied in the context of CS theories in [24]. For \(\Lambda_c \neq 0\), the parameter \(\Lambda_c\) can be set to one by rescaling \((H, P_a, N) \rightarrow \Lambda_c^{-1/2}(H, P_a, N)\). The most general symmetric bilinear form that one can define on the algebra is given by (5) together with

\[
B(H, N) = -\Lambda_c c_2, \quad B(P_a, P_b) = \Lambda_c c_2 \delta_{ab},
\] (7)

and requiring \(\Lambda_c \neq c_1^2/c_2^2\) ensures that the matrix is non-degenerate.

C. Extended Schrödinger algebra

The conformal extension of the Bargmann algebra is the Schrödinger algebra (with dynamical exponent \(z = 2\)). The Hamiltonian is extended to an \(SL(2, \mathbb{R})\) algebra consisting of dilatations \(D\) with \(z = 2\) and a special conformal generator \(K\) that form the subalgebra

\[
[D, H] = -2H, \quad [H, K] = D, \quad [D, K] = 2K.
\] (8)

The Schrödinger algebra is obtained by taking this \(SL(2, \mathbb{R})\) algebra and specifying how it acts on the Bargmann subalgebra (2), (3). This action is given by

\[
[H, G_a] = P_a, \quad [D, G_a] = -P_a, \\
[K, P_a] = -G_a.
\] (9)

The mass generator \(N\) remains central with respect to the full Schrödinger algebra.

It is possible to add dilatations to the extended Bargmann algebra of section II A by taking \([D, S] = 2S\). However this algebra has no non-degenerate metric. If we consider the full central extension (4), i.e. we add \(S\), \(Y\) and \(Z\) to the Bargmann algebra we can add the full \(SL(2, \mathbb{R})\) algebra (8) such that (9) continue to hold. The action of the \(SL(2, \mathbb{R})\) subalgebra on \(S\), \(Y\) and \(Z\) is non-trivial and fully determined by the Jacobi identities given all the other commutators. The result is that the nonzero commutators are

\[
[H, Y] = -Z, \quad [H, S] = -2Y, \quad [K, Y] = S,
\]

\[
[K, Z] = 2Y, \quad [D, S] = 2S, \quad [D, Z] = -2Z.
\] (10)

The extended Schrödinger algebra is thus given by (2)–(4), (8), (9) and (10). The corresponding symmetric bilinear form invariant under the extended Schrödinger algebra is

\[
B(H, S) = B(D, Y) = B(K, Z) = -B(J, N) = c_1, \\
B(P_a, G_b) = c_1 \epsilon_{ab}, \quad B(H, K) = -c_2, \\
B(D, D) = 2c_2, \quad B(J, J) = c_3
\] (11)

which is non-degenerate if \(c_1 \neq 0\).

III. NON-RELATIVISTIC CHERN–SIMONS ACTIONS

We now turn to study the form of the CS action (1) for each of these three algebras which have the Bargmann algebra as a subalgebra and allow for a non-degenerate metric.

A. Bargmann and Newton–Hooke invariant Chern–Simons actions

The extended Bargmann algebra can be obtained by setting \(\Lambda_c = 0\) in the extended Newton–Hooke algebra so we will construct the CS action using the metric (5) and (7). Expanding the gauge connection as \(A = H^\tau + P_a e^a + G_a \Omega^a + J + N m + S \zeta\), the CS action becomes

\[
\text{Tr} \left( A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right) =
\]

\[
2c_1 \left[ -\epsilon_{ab} R^a(G) \wedge e^b + \frac{1}{2} \epsilon_{ab} \tau \wedge \Omega^a \wedge \Omega^b - \Omega \wedge dm + \zeta \wedge d\tau + \Lambda_c \tau \wedge e^1 \wedge e^2 \right]
\]

\[
+ c_2 \left[ \Omega^a \wedge R^a(P) + 2 \zeta \wedge d\Omega + \Lambda_c e^a \wedge R^a(P) - 2 \Lambda_c \tau \wedge R(N) + \Lambda_c \Omega \wedge \Omega^a \wedge \tau \right]
\]

\[
+ c_3 \Omega \wedge d\Omega + 2 c_4 \tau \wedge d\Omega + c_5 \tau \wedge d\tau,
\] (12)

(see also [20, 24]) where the curvatures \(R^a(P), R^a(G)\) and \(R(N)\) are given by

\[
R^a(P) = de^a - \Omega^a \wedge \tau - \epsilon^{ab} \Omega^b, \quad R^a(G) = d\Omega^a - \epsilon^{ab} \Omega^b, \quad R(N) = dm - \Omega^a \wedge e^a.
\] (13)

These curvatures are defined by the expansion of the field strength

\[
F = dA + A \wedge A
= H R(H) + P_a R^a(P) + G_a R^a(G) + J R(J)
+ N R(N) + S R(S).
\] (14)

We see that \(\Lambda_c\) plays the role of a cosmological constant term (in the \(c_1\) term). The terms proportional to \(c_2\) \(\Lambda_c\) are
by themselves invariant under the gauge transformations \( \delta A = dA + [A, \Lambda] \).

The terms with coefficients \( c_4 \) and \( c_5 \) in (12) are not interesting as they can be removed by a field redefinition of \( \zeta \). This leads to a new value for the parameter in front of the \( \Omega \wedge d\Omega \) term. Hence we can always restrict ourselves to \( c_1, c_2 \) and \( c_3 \) and set to zero \( c_4 = c_5 = 0 \). When \( \Lambda_e = 0 \) the terms proportional to \( c_2 \) and \( c_3 \) are

\[
c_2 (\Omega^a \wedge R^a (G) + 2 \zeta \wedge d\Omega) + c_3 \Omega \wedge d\Omega. \tag{15}
\]

These can be thought of as the analogue of the Lorentz CS term. The term with coefficient \( c_2 \) is a novel Galilean boost invariant combination that starts as \( \Omega^a \wedge d\Omega^a \) plus extra terms to make it invariant. To see the invariance explicitly we give the transformations of the connections for \( \Lambda_e = 0 \) appearing in (15) that read

\[
d\Omega^a = d\lambda^a + e^{ab} (\lambda^b - \lambda^b \Omega), \quad d\Omega = d\lambda, \\
\delta \zeta = - e^{ab} \lambda^a \Omega. \tag{16}
\]

If we consider the CS theory on a manifold with a boundary they are expected to lead to Galilean boost and rotation anomalies on the boundary theory. In the simplest setting with \( c_2 = c_3 = 0 \) the \( \zeta \) equation of motion is \( dr = 0 \). In section IV A we will see that this corresponds to having no torsion in the Newton–Cartan description, or what is the same, projectable HL gravity [13].

### B. Schrödinger invariant Chern–Simons action

The extended Schrödinger algebra is (2)–(4), (8), (9) and (10). We expand the gauge field as

\[
A = H \tau + P_a e^a + G_{\omega} \omega^a + J_\omega + N m + D b + K f + S \zeta + Y \alpha + Z \beta. \tag{17}
\]

Using the metric on the Lie algebra (11) the Chern–Simons action can be written as

\[
\mathcal{L} = 2c_1 \left[ \mathcal{R}^2 (G) \cap \epsilon^1 - \mathcal{R}^1 (G) \cap \epsilon^2 + \tau \wedge \omega^1 \wedge \omega^2 - m \wedge d\omega - f \wedge \epsilon^1 \wedge \epsilon^2 + \zeta \wedge (d\tau - 2b \wedge \tau) + \alpha \wedge (db - f \wedge \tau) + \beta \wedge (df + 2b \wedge f) + 2c_2 \left[ b \wedge db - \tau \wedge df + 2b \wedge \tau \wedge f \right] + \zeta \wedge \omega \right], \tag{18}
\]

where the curvature \( \mathcal{R}^a (G) \) is given by

\[
\mathcal{R}^a (G) = d\omega^a + e^{ab} \omega^b \wedge \omega - \omega^a \wedge b - b \wedge \epsilon^a. \tag{19}
\]

There is no redefinition of the connections \( \zeta, \alpha \) and \( \beta \) that allows one to remove the term with coefficient \( c_2 \) entirely. It transforms under the \( SL(2, \mathbb{R}) \) transformations inside the extended Schrödinger algebra. It would be interesting to see if it corresponds to some anomaly for a boundary theory like a Weyl-type anomaly.

The equation of motion of \( \zeta \) now imposes the on-shell condition that \( d\tau = 2b \wedge \tau \) which is equivalent to \( \tau \wedge d\tau = 0 \). In the language of Newton–Cartan geometry this corresponds to twistless torsional Newton–Cartan (TTNC) geometry [3, 26] or what is the same non-projectable HL gravity [13]. The details will be given in section V A.

### IV. Chern–Simons action for 3D Projectable Hořava–Lifshitz Gravity

We know from [27] that gauging the Bargmann algebra leads to Newton–Cartan (NC) geometry. In [13] it was shown that dynamical Newton–Cartan geometry is field redefinition equivalent to projectable Hořava–Lifshitz gravity as presented in [16]. Hence we should be able to show that the CS action given in section III A is equivalent to a 3D projectable HL gravity theory.

#### A. Bargmann invariant projectable Hořava–Lifshitz gravity

We will now rewrite (12) with only the \( c_1 \) coefficient nonzero in a metric form using the language of Newton–Cartan (NC) geometry. The connections \( \tau_{\mu} \) and \( e_{\mu}^a \) are the vielbeins of NC geometry. We define inverse vielbeins \( v^\mu \) and \( e_{\mu}^a \) via \( \delta_{\nu}^\mu = -v^\mu \tau_{\nu} + e_{\mu}^a \omega^a \) so \( v^\mu \tau_{\mu} = -1, e_{\mu}^a \mu = 0, v^\mu e_{\mu}^a = 0 \) and \( e_{\mu}^a e_{\mu}^b = \delta^a_b \). It can be shown that the first term in the CS action (12) can be written as

\[
R^2 (G) \cap \epsilon^1 - R^1 (G) \cap \epsilon^2 = v^\mu e_{\mu}^a R_{\mu \nu} a (G) \tau \wedge \epsilon^1 \wedge \epsilon^2. \tag{20}
\]

With \( m = -v^\mu m_{\mu} \tau + e_{\mu}^a m_{\mu} e_{\mu}^a \) it follows that the third term in (12) becomes

\[
m \wedge R (J) = - \left[ - \frac{1}{2} v^\mu m_{\mu} R - e_{\mu}^a m_{\mu} v^a e_{\mu}^a R_{\mu \nu} (J) \right] + e_{\mu}^a m_{\mu} v^a e_{\mu}^a R_{\mu \nu} (J), \tag{21}
\]

where we used that

\[
R_{ab} (J) = e_{a}^c e_{b}^d R_{\mu \nu} (J) = \frac{1}{2} \epsilon_{ab} R. \tag{22}
\]

The action (12) is written in a first order formalism where all the connections in \( A_\mu \) are treated as independent variables. The form we are looking for treats the NC variables \( \tau_{\mu}, e_{\mu}^a \) and \( m_{\mu} \) as independent variables. Hence we will integrate out the variables \( \Omega^a, \Omega \) and \( \zeta \). Their equations of motion are the NC curvature constraints [27] \( R^a (P) = 0, R (N) = 0 \) and \( R (H) = d\tau = 0 \) where the curvatures are given in (13). These are solved by expressing \( \Omega_{\mu}^a \) and \( \Omega_{\mu} \) in terms of \( \tau_{\mu}, e_{\mu}^a \) (their inverse) and \( m_{\mu} \) where \( d\tau = 0 \). The off-shell implementation of the curvature constraints makes the theory diffeomorphism invariant because the NC curvature constraints imply that the transformations of \( \tau_{\mu}, e_{\mu}^a \) and \( m_{\mu} \) constitute diffeomorphisms and local \( G^a, J, N \) transformations [27].
In order to rewrite the CS action it will be useful to employ the following Bianchi identity
\[ dR^a(P) - e^{ab} \Omega \wedge R^b(P) - \Omega^a \wedge d\tau = -R^a(G) \wedge \tau - e^{ab} R(J) \wedge e^b. \] (23)

Using the curvature constraints \( R^a(P) = 0 \) and \( d\tau = 0 \) which will be implemented off-shell we find \( R^a(G) \wedge \tau + e^{ab} R(J) \wedge e^b = 0 \). From this we conclude that
\[ \begin{align*}
\nu^\mu e^\nu R_{\mu
u}(J) &= -e^{ab}_\nu R_{\mu
u}^a(G), \\
\nu^\mu e^\nu R_{\mu
u}(J) &= e^{ab}_\nu R_{\mu
u}^a(G).
\end{align*} \]
(24)

Using that \( \Omega^1 = -\nu^\mu \Omega^1_{\mu} + e^a \Omega^a_{\mu} e^a \) we conclude that (12), with \( c_1 = 1 \) and all other constants zero, can be written as
\[ \mathcal{L} = e \left( 2 \hat{\nu}^\rho e^\nu R_{\mu
u}^a(G) + (e^{ab}_\mu e^\nu - e^a e^b_\nu) \Omega^a_{\mu} \Omega^b_{\nu} \right. \\
&\left. + \nu^\mu m_\mu J \right), \]
(25)
where \( e = \tau \wedge e^1 \wedge e^2 \).

To massage this expression further we need a notion of a covariant derivative. This can be introduced via the vielbein postulates
\[ \begin{align*}
D_{\mu} \tau_\nu &= \partial_{\mu} \tau_\nu - \Gamma^\rho_{\mu\nu} \tau_\rho = 0, \\
D_{\mu} e^a_\nu &= \partial_{\mu} e^a_\nu - \Gamma^\rho_{\mu\nu} e^a_\rho - \Omega^a_{\mu} \tau_\nu - e^{ab} \Omega^b_{\mu} e^b_\nu = 0,
\end{align*} \]
(26)
where we take for \( \Gamma^\rho_{\mu\nu} \)
\[ \Gamma^\rho_{\mu\nu} = -\hat{\nu}^\sigma \partial_{\mu} \tau_\sigma + \frac{1}{2} \hat{\rho}^\sigma \left( \partial_{\mu} \hat{h}_{\sigma\nu} + \partial_{\nu} \hat{h}_{\sigma\mu} - \partial_{\sigma} \hat{h}_{\mu\nu} \right), \]
(27)
in which
\[ \begin{align*}
\hat{\psi}_\mu &= \psi_\mu - h^\mu \nu m_\nu, \\
\hat{h}_{\mu\nu} &= h_{\mu\nu} - \tau_\mu m_\nu - \tau_\nu m_\mu, \\
\hat{h}_{\mu\nu} &= \delta_{ab} a^a_\mu b^b_\nu, \quad h^{\mu\nu} = \delta_{ab} e^a_\mu e^b_\nu.
\end{align*} \]
(28)

The connection (27) is a symmetric connection for \( d\tau = 0 \) that is invariant under \( G^a \), \( J^a \), and \( N \) transformations. The vielbein postulates relate \( \Gamma^\rho_{\mu\nu} \) to \( \Omega^a_{\mu} \) and \( \Omega^a_{\nu} \). These relations are the same as the expressions obtained by solving the curvature constraints \( R_{\mu
u}(P) = 0 \), \( R_{\mu\nu}(N) = 0 \) for \( \Omega^a_{\mu} \) and \( \Omega^a_{\nu} \). We denote by \( \nabla_{\mu} \) the covariant derivative containing the connection \( \Gamma^\rho_{\mu\nu} \). For \( d\tau = 0 \) we have
\[ \begin{align*}
\left[ \nabla_{\mu}, \nabla_{\nu} \right] X_\rho &= R_{\mu\nu\sigma\rho} X_\rho, \\
R_{\mu\nu\sigma\rho} &= e^a_\alpha \Gamma^\sigma_{\mu\rho} - e^a_\sigma \Gamma^\rho_{\mu\nu} - e^a_\nu \Gamma^\sigma_{\mu\rho} (J) e^{ab}.
\end{align*} \]
(29)

We now switch to employing a Lagrangian density rather then a 3-form. Using (29) and the fact that from the vielbein postulates it follows that \( \Omega^a_{\mu} e^{\nu} = \nabla_{\nu} e^{a} \) we find after performing a few partial integrations and writing \( \nu^\mu = \nu^\mu + h^\mu \nu m_\nu \) that
\[ \begin{align*}
\mathcal{L} &= e \left( -\nabla_\mu \nu^\nu \nabla_{\nu} \nu^\nu + \nabla_\nu \nu^\mu \nabla_\mu \nu^\nu + \nu^\mu m_\mu J \right. \\
&\left. + \left( h^{\mu \rho} h^{\nu \sigma} - h^{\mu \sigma} h^{\nu \rho} \right) \nabla_\mu m_\rho \nabla_\nu m_\sigma \right). \]
(30)

Finally, using partial integrations which give rise to a commutator on one of the \( m_\mu \) vectors as well as properties of the Riemann tensor, it can be shown that
\[ \mathcal{L} = e \left( \hat{h}^{\mu \rho} h^{\nu \sigma} K_{\mu \nu} K_{\rho \sigma} - \left( h^{\mu \nu} K_{\mu \nu} \right)^2 - \Phi R \right), \]
(31)
where
\[ \Phi = -\nu^\mu m_\mu + \frac{1}{2} h^{\mu \nu} m_\mu m_\nu. \]
(32)

This is the same action as the action\(^5\) (10.10) given in [13] which in turn is based on the NC version of the results of [16]. Note that the extrinsic curvature is given by \( h^{\mu \nu} K_{\mu \nu} = - \nabla_\mu \dot{\nu}^\mu \). One observes that the HL \( \lambda \) parameter which can appear between the two extrinsic curvature terms is equal to unity in (31).

If we include \( \Lambda_c \) appearing in the extended Newton–Hooke algebra we simply end up with the same Lagrangian to which we add \( c \Lambda_c \). We note that the sign of the cosmological constant term is not fixed.

The Lagrangian (31) should be thought of as depending on the variables \( \tau_\mu = \partial_\mu \tau, \Phi \) and \( \hat{h}_{\mu\nu} \) and their derivatives. In projectable HL gravity \( \tau \) is identified with the ADM time coordinate leading to foliation preserving diffeomorphism invariance.

### B. Solutions

We will solve the equations of motion of (12), \( F = 0 \) with \( F \) expanded as in (14), locally for the case with \( c_2 = c_3 = c_4 = c_5 = 0 \) but with \( \Lambda_c \) arbitrary. Under a gauge transformation the connection transforms as \( \delta A = d\lambda + [A, \Lambda] \). We will write \( \Lambda = \lambda^\mu A_\mu + \Sigma \), where \( \Sigma = G_a \lambda^a + J^a + N \sigma + S K \). In components these are the following transformations
\[ \delta \tau_{\mu} = \lambda \partial_{\mu}, \quad \delta e^a_\mu = \xi^a_\mu + (\lambda^a_\mu + \gamma^a_\mu) \delta e^b_\mu, \quad \delta e^a_\mu = \lambda^a_\mu + \gamma^a_\mu \Omega^a_{\mu}. \]
(33)

Without loss of generality we can fix the gauge redundancy by setting \( \partial_{\mu} = \delta^\mu, e^a_\mu = \delta^a_\mu \), \( \Omega^a_{\mu} = 0, \Omega^a = -\Lambda_a \delta^a x^b \) and \( m = \frac{1}{2} \Lambda_a x^a x^b dt \). The relation between NC geometry and the ADM form of the HL metric
\[ ds^2 = -N^2 dt^2 + \gamma_{ij} \left( dx^i + N^i dt \right) \left( dx^j + N^j dt \right). \]
(34)

\(^5\) In the analysis of [13] a different choice was made for the connection \( \Gamma_{\mu\nu}^\rho \) that was denoted by \( \Gamma_{\mu\nu}^{\rho}_{\mu\nu} \). This other choice is related to (39) via equations (5.7) and (5.3) of [13]. It can be shown that the form of the Lagrangian is not affected by these choices.
uses the following identifications (see section 8 of [13])

\[\begin{align*}
\tau_1 &= N, \quad \tau_1 = 0, \quad h_{ij} = \gamma_{ij}, \quad h_{ii} = h = 0, \\
m_t &= 0, \quad m_i = -N^{-1} \gamma_{ij} N^j.
\end{align*}\] (35)

This identification only works in special gauges of the CS theory. When written in the form (31) the HL theory is not a Lorentzian metric theory. In order to make contact with the ADM parametrization we take \(\sigma = -\frac{1}{2} \Lambda_c x^i x^i\), so that \(m_t = 0\) and \(m_i = \partial_i \sigma = -\Lambda_c x^i\).

Hence the full solution for \(\tau, e^a, m\) and \(\nu\) is given by \(\nu = dt, e^a = \delta^a_{\rho} dx^\rho, m = -\Lambda_c x^3 dx^1\). This corresponds to the ADM variables \(N = 1, N^3 = \Lambda_c x^3, h_{ij} = \delta_{ij}\). By making the coordinate transformation \(x^i = e^{-\Lambda_c t^2/2} X^i\) this becomes

\[ds^2 = -dt^2 + e^{-\Lambda_c t^2} dX^i dX^i.\] (36)

We thus find cosmological solutions for \(\Lambda_c \neq 0\). Of course this is only true sufficiently locally, as there can be non-trivial identifications on a global level.

V. CHERN–SIMONS ACTIONS FOR 3D NON-PROJECTABLE HOŘÁVA–LIFSHITZ GRAVITY

In [26] it was shown that gauging the Schrödinger algebra leads to torsional Newton–Cartan geometry with twistless torsion \(\tau \wedge d\tau = 0\). In [13] it has been shown that twistless torsional Newton–Cartan geometry (TTNC) corresponds to non-projectable HL gravity. We refer to [28] for an alternative derivation of the same connection between dynamical TTNC geometry and HL gravity. We now show that the CS action given in section III B is equivalent to a 3D non-projectable HL gravity theory.

A. Schrödinger gravity

Our goal will be to rewrite the CS Lagrangian (18) with \(c_2 = c_3 = 0\) into the metric formulation of TTNC geometry. As in the case discussed in section IV A we will go from a first order formalism to a second order one by integrating out the connections \(\omega^a, \omega, \zeta\) and \(\alpha\). The equations of motion corresponding to varying these connections are the curvature constraints \(\tilde{R}^a(P) = 0, \tilde{R}(N) = 0, \tilde{R}(H) = 0,\) and \(\tilde{R}(D) = 0\). These curvatures can be computed by expanding the curvature of (17) as

\[F = H \tilde{R}(H) + P_a \tilde{R}^a(P) + G_a \tilde{R}^a(G) + J \tilde{R}(J) + N \tilde{R}(N) + D \tilde{R}(D) + K \tilde{R}(K) + S \tilde{R}(S) + Y \tilde{R}(Y) + Z \tilde{R}(Z).\] (37)

Solving the constraints \(\tilde{R}^a(P) = 0, \tilde{R}(N) = 0, \tilde{R}(H) = 0\) and \(\tilde{R}(D) = 0\) was done in [26] and the solution can be expressed as giving \(\omega^a, \omega, \nu\) and \(f\) in terms of the vielbeins \(\tau \) (obeying \(\tau \wedge d\tau = 0\)), \(e^a, m\) and the components \(\hat{\omega}^a b_{\mu}\) and \(\hat{\omega}^a f_{\mu}\). The curvature constraints also allow us to rewrite the algebra of gauge transformations acting on these fields as the algebra of diffeomorphisms and internal transformations consisting of local \(G^a, J, N, D\) and \(K\) transformations.

The expressions for \(\omega^a\) and \(\omega\) can also be obtained from a vielbein postulate for a specific realization of an affine connection \(\Gamma^a_{\mu\nu}\) that is invariant under all the transformations except those that are diffeomorphisms. These vielbein postulates are

\[\begin{align*}
D_\mu \tau_\nu &= \partial_\mu \tau_\nu - \tilde{\Gamma}^{\rho}_{\mu\nu} \tau_\rho - 2b_\mu \tau_{\nu} = 0, \\
D_\rho e^a_\nu &= \partial_\rho e^a_\nu - \tilde{\Gamma}^{\rho}_{\mu\nu} e^a_\rho - \omega^a_\mu \tau_\nu - \epsilon^{ab} \omega^b_\mu e^b_\nu - b_\mu e^a_\nu = 0,
\end{align*}\] (38)

where we take for \(\tilde{\Gamma}^{\rho}_{\mu\nu}\)

\[\tilde{\Gamma}^{\rho}_{\mu\nu} = -\hat{\omega}^a (\partial_\mu b_a - 2b_\mu) \tau_\nu + \frac{1}{2} h^{\rho\sigma} \left[(\partial_\nu - 2b_\nu) \hat{h}_{\mu\sigma} - (\partial_\nu - 2b_\nu) \hat{h}_{\mu\nu}\right].\] (39)

The connection \(\tilde{\Gamma}^{\rho}_{\mu\nu}\) is symmetric. The associated curvature is \([\tilde{\nabla}_\mu, \tilde{\nabla}_\nu]X_\sigma = \tilde{R}_{\mu\nu\rho\sigma} X_\rho\) for any vector \(X_\rho\) where [13]

\[\tilde{\nabla}_\mu \tau_\nu = -e^{cd} e_\epsilon c_{\epsilon d} \tilde{R}_{\mu\nu}(J) + c_{\epsilon d} \tau_\rho \tilde{R}_{\mu\nu}^c(G) - \delta^a_\mu \tau_\rho f_\rho + \delta^a_\nu \tau_\rho f_\rho + \delta^a_\nu \left(f_\rho \tau_\nu - f_\nu \tau_\rho\right).\] (40)

The equations of motion for \(\zeta\) and \(\alpha\) are solved by

\[\begin{align*}
b_\nu &= \frac{1}{2} \hat{\omega}^a (\partial_\mu b_a - 2b_\mu) \tau_\nu - \hat{\omega}^a b_\mu \tau_\nu, \\
f_\nu &= \hat{\omega}^a (\partial_\mu b_\rho - \partial_\nu b_\mu) - \hat{\omega}^a f_\mu \tau_\nu,
\end{align*}\] (41)

which is why we are left with \(\hat{\omega}^a b_\mu\) and \(\hat{\omega}^a f_\mu\) as independent variables on top of the usual TTNC variables \(\epsilon^a, m\) and \(\nu\). These expressions satisfy \(c_{\epsilon d}^e c_{\epsilon d} R_{\nu\mu}(K) = 0\).

Using the curvature constraints the Lagrangian (18) for \(c_2 = c_3 = 0\) and \(c_1 = 1\) can be written as

\[\begin{align*}
\mathcal{L} &= 2 \left( e^a \wedge \omega^a \wedge \omega - \tau \wedge \omega^1 \wedge \omega^2 + f \wedge e^1 \wedge e^2 + \beta \wedge (df + 2b \wedge f) \right).
\end{align*}\] (42)

With the help of the vielbein postulates this can be further rewritten as

\[\begin{align*}
\mathcal{L} &= -\left(2 e^{\mu\nu} m_\rho \partial_\rho \omega_\nu + e^{\mu\nu} \epsilon_{\sigma\lambda\tau} \tau^\sigma \tilde{\nabla}_\nu \nu^\lambda \tilde{\nabla}_\nu \nu^\lambdaight) \\
&\quad + 2 \hat{\omega}^a f_\mu \tau \wedge e^1 \wedge e^2 + 2 \beta \wedge (df + 2b \wedge f).\] (43)

Using the above mentioned results multiple times as well as (28) and after performing various partial integrations a lengthy calculation gives

\[\begin{align*}
\mathcal{L} &= e \left[ (\hat{\omega}^{a\mu} \hat{\omega}^{b\nu} - \hat{\omega}^{a\nu} \hat{\omega}^{b\mu}) \tilde{h}_{\alpha\beta} \tilde{\nabla}_\alpha \tilde{\nabla}_\beta \nu^\lambda \nu^\lambda - \tilde{\Phi} \tilde{R} \right] \\
&\quad - 2 \hat{\omega}^a f_\mu + 2 \epsilon^{\mu\nu} \tau_\rho \hat{\omega}^\beta_\nu R_{\rho\sigma}(K),
\end{align*}\] (44)

where we defined \(\tilde{R}_{ab}(J) = e^a_\mu e^b_\mu \tilde{R}_{\mu\nu}(J) \equiv \frac{1}{2} \xi_{ab} \tilde{R}.\)
The next step is to go from the connection $\tilde{\Gamma}^{\mu}_{\nu\rho}$ to the torsionful connection (39). The torsion comes from the fact that for TTNC we have $\tau \wedge dt = 0$ so that the first term in (39) is no longer symmetric. The difference between these two connections is a tensor depending on $b_\mu$. We find

$$\mathcal{L} = e \left[ (h^{\alpha\nu} h^{\beta\mu} - h^{\alpha\mu} h^{\beta\nu}) K_{\alpha\mu} K_{\beta\nu} + 2 \tilde{\theta}^{\alpha\mu} b_\mu h^{\beta\rho} K_{\rho\nu} - 2 (\tilde{\theta}^{\alpha\mu} b_\mu)^2 - \tilde{\Phi} k - 2 \tilde{\phi} f_\mu + 2 \tilde{\phi}^{\mu\rho} \tau_\rho \tilde{\theta}^\beta_\nu R^\nu_\mu (K) \right].$$

(45)

If we express the spatial curvature $\tilde{\mathcal{R}}$ in terms of the spatial curvature $\mathcal{R}$ defined with respect to the $\Omega$ connection in (22) we find $6 \tilde{\mathcal{R}} = \mathcal{R} - \nabla_\mu (h^{\alpha\mu} a_\alpha)$. The vector $a_\mu$ is called the acceleration vector in HL gravity. In TTNC geometry it is known as the torsion vector $a_\mu = L_\nu T_\mu$, since all information about the torsion of (39) is contained in $a_\mu$. The extrinsic curvatures $K_\mu^\rho$ obey $h^{\mu\rho} K_{\mu\rho} = -\nabla_\mu \tilde{\phi}^\nu$. We see that the DeWitt metric has $\lambda = 1$ where $\lambda$ is the parameter in HL gravity that measures the relative coefficient of the two extrinsic curvature terms. The difference with (31) is that now there are couplings to $\tilde{\theta}^{\alpha\mu} b_\mu$. We note that $b_\mu$ and $f_\mu$ transform as $\delta b_\mu = \partial_\mu \Lambda_D + \Lambda_K \tau_\mu$, $\delta f_\mu = \partial_\mu \Lambda_K + 2 \Lambda_K b_\mu - 2 \Lambda_D f_\mu$, where $\Lambda_D$ and $\Lambda_K$ are the local parameters of the $D$ and $K$ transformations. We can thus gauge fix the $K$ transformations by setting $\tilde{\theta}^{\alpha\mu} b_\mu$ to any desired value.

Finally we rewrite the last term in (45). Using that for TTNC we can always write $\tau_\mu = N \partial_\mu \tau$, it can be shown that

$$\varepsilon^{\mu\rho\tau} \tau_\rho \tilde{\theta}^\beta_\nu R^\nu_\mu (K) = -\frac{1}{4} \varepsilon^{\mu\rho\beta} \beta_\rho \tau_\mu (\partial_\mu + 2 a_\mu) I,$$

(46)

where $I$ is defined as $I = B^2 - 4 (\tilde{\theta}^{\alpha\mu} b_\mu)^2 + 2 \tilde{\theta}^{\alpha\mu} \partial_\mu (B - 2 \tilde{\theta}^{\alpha\mu} b_\mu) - 4 \tilde{\theta}^{\alpha\mu} f_\mu$, in which $B$ denotes the quantity $B = \tilde{\theta}^{\alpha\mu} N^{-1} \partial_\mu N$. Our final result is thus (45) with (46). The action depends on the variables $\tau_\mu = N \partial_\mu \tau$, $\tilde{h}^{\mu\nu}$, $\tilde{\Phi}$, $\tilde{\theta}^{\alpha\mu} b_\mu$, $\tilde{\theta}^{\alpha\mu} f_\mu$ and $\beta_\mu$. The equation of motion for $\beta_\mu$ allows us to solve for $\tilde{\theta}^{\alpha\mu} f_\mu$ on-shell.

The Lagrangian (45) provides a new way of constructing conformal actions for non-projectable HL gravity that we refer to as Schrödinger gravity. The main difference with the $z = 2$ Weyl invariant construction of [13, 26] is that we do not need to introduce a Stückelberg scalar, called $\chi$ in [13, 26]. This Stückelberg scalar was needed in order to construct a $z = 2$ Weyl invariant combination of extrinsic curvature terms based on a DeWitt metric with $\lambda$ parameter 1/2, i.e. $\left( h^{\alpha\mu} h^{\beta\mu} - \frac{1}{2} h^{\alpha\mu} h^{\beta\nu} \right) K_{\alpha\beta}^\nu K_{\mu\beta}^\nu$ where $K_{\mu\beta}^\nu$ is the extrinsic curvature scalar with $m_\mu$ replaced by $m_\mu - \partial_\mu \chi$ (see [13] for details).

**B. Lifshitz solutions**

The Schrödinger invariant CS theory (18) with $c_2 = c_3 = 0$ admits $z = 2$ Lifshitz solutions. It can be readily verified that the following expressions solve the flatness conditions $F = dA + A \wedge A = 0$,

$$\tau = \frac{dt}{r^\epsilon}, \ c_1 = \frac{dr}{r}, \ c_2 = \frac{dx}{r}, \ b = \frac{dr}{r}, \ \beta = -\frac{dx}{r},$$

(47)

with all other connections equal to zero. If we use the relation to the ADM description of HL gravity expressed in (34) and (35) we find the $z = 2$ Lifshitz metric

$$ds^2 = -\frac{dt^2}{r^4} + \frac{dr^2}{r^2} + \frac{dx^2}{r^2}.$$  

(48)

The solution has a simpler form. If we denote $b = e^{(l-D-2)\rho}$, where $r = e^{-\rho}$, then the Lifshitz solution can be written as $A = b^{-1} a b + b^{-1} K b$, where $a = H dt + (P_2 - Z) dx$.

The 3D Lifshitz solution with $z = 2$ was also found in the context of CS theories for higher spin theories [29, 30]. However, it was pointed out in [31] that this interpretation is problematic due to a degeneracy problem: the spin-connection cannot be determined from the torsion-free equation. Put another way the non-relativistic solutions of $SL(N, \mathbb{R}) \times SL(N, \mathbb{R})$ CS theory are not equivalent to metric solutions. Here we show that the solution (47) naturally emerges from a Newton–Cartan Chern–Simons theory which is not a Lorentzian metric theory.

**VI. DISCUSSION**

The results obtained in this paper open up for a number of interesting applications and extensions. First of all, it will be interesting to examine CS actions for other non-relativistic algebras, such as the Galilean conformal algebra, and likewise for algebras that play a role in ultra-relativistic limits, such as the Carroll algebra. In the latter case, one expects a connection to the 3D Carrollian gravity of Ref. [32].

Another worthwhile direction to pursue is to consider the CS actions of this paper in the presence of non-trivial boundaries, and consider aspects of edge physics as performed e.g. in [33] for quantum Hall states. In particular it would interesting to study the role of the Galilean boost CS term (with coefficient $c_2$ in (15)) in relation to anomalies in this context. Further one could try to find a microscopic description of the extended Bargmann CS theory, e.g. using non-relativistic fermions with a mass gap such that the effective theory below the mass gap is described by the extended Bargmann CS theory. Moreover it is tempting to consider the CS theory with the Galilean...
boost and rotation CS terms (with coefficients $c_2$ and $c_3$) in (12) as the non-relativistic analogue of topologically massive gravity [34, 35]. To explore this idea further one would for example like to understand the solutions of the theory.

An important application of our findings is to use the Schrödinger invariant CS theory as a bulk holographic action for $z = 2$ Lifshitz space-times. The resulting Schrödinger gravity may be regarded as a very minimal setup to do Lifshitz holography (see [36] for a review). Using HL gravity in this context was proposed in [37, 38] and the CS reformulation of this paper is expected to provide new insights. In particular the CS formulation can give a proper definition of black objects (provided they exist) in these non-relativistic gravity theories, and thereby also give information on boundary hydrodynamics and other dynamical properties. We also stress that our results point towards Lifshitz vacua appearing naturally in non-relativistic gravity, rather than in Lorentzian metric theories. It would thus be interesting to revisit some of the pathologies [39] and other properties (see e.g. [40]) that have been examined within the framework of Riemannian geometry.

Another relevant aspect to pursue, in close parallel with higher spin gravity, is to employ the techniques of [41, 42] to find the corresponding generalization of holographic entanglement [43] for non-relativistic CS gravity. Moreover, a further extension of our ideas to non-relativistic higher spin gravity could be an interesting direction. Similar in spirit, an $SL(2,\mathbb{R}) \times U(1)$ CS theory (called lower spin gravity) was argued to be the minimal setup to holographically describe warped CFTs [44]. In this light one could try to find a relation between the present CS theories or some close cousin thereof and 2-dimensional warped CFTs [45].

All the HL gravity actions obtained via our CS formulation have the property that the HL $\lambda$ parameter, which appears in the DeWitt metric contracting the extrinsic curvatures, is equal to unity. It would thus be interesting to see whether by adding appropriate scalar matter fields, i.e. considering CS matter theories, we can construct more general HL actions for which $\lambda \neq 1$.

Upon the completion of this work we were informed by Eric Bergshoeff and Jan Rosseel of the paper [46] in which it is shown that the Bargmann invariant CS action can be obtained by a non-relativistic limit from three-dimensional GR, augmented with two vector fields. This work also obtains a supersymmetric generalization, which is thus a supersymmetric extension of 3D projectable HL gravity.

Acknowledgments

We would like to thank Eric Bergshoeff, Joaquim Gomis, Daniel Grumiller, Diego Hofman, Kristian Jensen, Wout Merbis and Jan Rosseel for valuable discussions. The work of JH is supported by the advanced ERC grant ‘Symmetries and Dualities in Gravity and M-theory’ of Marc Henneaux. The work of NO is supported in part by the Danish National Research Foundation project “New horizons in particle and condensed matter physics from black holes”. JH and NO gratefully acknowledge support from the Simons Center for Geometry and Physics, Stony Brook University at which some of the research for this paper was performed.
