Keywords: CCL2, colon cancer, liver metastasis, myeloid cell recruitment

Abbreviations: CRC, colorectal cancer; KO, knockout; LLC, Lewis lung carcinoma

Tumor-infiltrating immune cells play important roles in metastasis. We have recently revealed the recruitment of a specific myeloid cell subset (CD11b/Gr1mid) to hepatic metastases. Such a recruitment relies on CCL2/CCR2 signaling and acts to sustain metastatic growth. A similar cell subset was identified in patients bearing hepatic metastases of colorectal cancer, highlighting the potential therapeutic relevance of our findings.

Colorectal cancer (CRC) is a highly prevalent disease characterized by high mortality rates and often complicated by metastatic dissemination, most frequently to the liver. Surgical resection constitutes the most effective therapeutic option for patients with hepatic metastases, although this option is not always feasible due to the extent of metastatic spread. The development of metastases is influenced by intricate interactions between cancer and immune cells. Tumor-associated immune cells, particularly myeloid cells, have been shown to play critical roles in the metastatic cascade. Indeed, the recruitment of inflammatory monocytes, macrophages and granulocytes to the metastatic microenvironment is essential for the development of pulmonary metastases from breast carcinomas and other solid tumors. Although the role of myeloid cells in the metastatic dissemination of CRC to the liver has been less extensively studied, a tumor-infiltrating myeloid cell population (CD11b+/CD34+Gr1− cells) has been shown to promote the hepatic expansion of CRC cells in the liver.

Using murine models, we have recently characterized three myeloid cell populations (CD11b/Gr1h svg, CD11b/Gr1mid and CD11b/Gr1bw) in the hepatic tumor microenvironment, each featuring a distinct morphology, distinct surface marker expression and distinct profile of secreted inflammatory mediators. Among these myeloid cell subsets, CD11b/Gr1mid cells increased dramatically as metastases progressed. This pattern of myeloid cell accumulation was tumor-specific, as we observed it only in mice bearing metastasis from MC38 CRC and Lewis lung carcinoma (LLC) but not B16F1 melanoma cells.

We have also demonstrated the functional importance of CD11b/Gr1mid and CD11b/Gr1bw myeloid cells in the progression of hepatic metastases. The depletion of these cells (as obtained by the administration of diphtheria toxin A in transgenic mice bearing the diphtheria toxin receptor under the control of the CD11b promoter) in animals bearing established liver metastases caused a striking decrease in hepatic tumor burden. Previous studies have established that tumor-infiltrating myeloid cells can support the metastatic cascade at various levels, including early stages of the metastatic process (i.e., the formation of pre-metastatic niche, invasion and extravasation from blood vessels), metastatic outgrowth and colonization, as well as late steps of the metastatic cascade. In our model, CD11b/Gr1mid and CD11b/Gr1bw cells were important for the sustained growth of metastatic tumor cells during the late stages of the metastatic process. Thus, we propose that these cells might be a useful therapeutic target for the treatment of established liver metastases.

We verified the fact that CD11b/Gr1mid cells originate in the bone marrow by adoptive cell transfer and demonstrated that these cells home to the liver tumor microenvironment in response to the release of CCL2 by CRC cells (Fig. 1). The inhibition of CCL2 signaling using a CCL2-specific lentiviral-based short-hairpin RNA (shRNA) as well as the absence of its cognate receptor in Ccr2 knockout mice inhibited the recruitment of CD11b/Gr1mid cells, resulting in a marked reduction of tumor burden. The deregulation of CCL2/CCR2 is common in cancer, and it has been implicated in the progression of a number of different primary neoplasms. We have analyzed the serum of CRC patients, observing a correlation between the levels of CCL2 and disease stage, in line with previous results. In addition, the analysis of tissue samples from CRC patients bearing hepatic metastases revealed CD11b+/CCR2+ cells...
the host immune system to their own ends. However, clinical benefits may only be gained by targeting multiple chemokine receptors, presumably in a patient-specific manner. A better understanding of the roles of tumor-infiltrating myeloid cells in metastatic dissemination is urgently required to specifically target the mechanisms whereby these cells influence metastatic progression.

Figure 1. The metastatic liver microenvironment. Three CD11b+ myeloid populations expressing different levels of Gr1 (Gr1low, Gr1mid and Gr1high) were observed in the metastatic liver microenvironment. Metastatic tumor cells secrete CCL2, hence recruiting CCR2-expressing Gr1mid cells from the bone marrow. Cells sharing features with such Gr1mid myeloid population (CD11b+CCR2+) were found in metastatic liver tissues from some colorectal cancer patients (inset).
