Abstract
We prove that every rayless graph has an unfriendly partition.

1 Introduction

A bipartition of the vertex set of a graph is *unfriendly* if every vertex has at least as many neighbours in the other class as in its own. The following conjecture is one of the best-known open problems in infinite graph theory.

**Unfriendly Partition Conjecture.** Every countable graph admits an unfriendly partition of its vertex set.

Clearly, every finite graph has an unfriendly partition: just take any bipartition that maximizes the number of edges between the partition classes. For infinite graphs however, few results are known. Shelah and Milner [4] constructed uncountable graphs that admit no unfriendly partitions, thereby disproving the original folklore conjecture that every graph has an unfriendly partition. (They attribute this conjecture to R. Cowan and W. Emerson, unpublished.) It is an easy exercise in compactness to deduce from the finite theorem that every locally finite graph has an unfriendly partition. (Aharoni, Milner and Prikry [2] strengthened this fact by proving that every graph with only finitely many vertices of infinite degree has an unfriendly partition.

At the other end of the spectrum, it is easy to prove that countable graphs in which only finitely many vertices have finite degree have unfriendly partitions. Since the counterexamples from [4] have no vertices of finite degree, the countability assumption here cannot be dropped.

The main aim of this paper is to prove that all rayless graphs, countable or not, have unfriendly partitions:

**Theorem 1.1.** Every rayless graph has an unfriendly partition.

*Supported by a GIF grant.*
For the proof of this theorem we used a tool developed by Schmidt [3], which assigns to every rayless graph an ordinal number, its rank. This rank enables us to prove Theorem [14] by transfinite induction.

Closer inspection of the proof reveals that it does not depend on the graphs being rayless, but only on the existence of such a kind of rank. Extending the method to more general rank functions, one can indeed strengthen Theorem [11] in various ways. One such strengthening obtained in Section [4] is this:

**Theorem 1.2.** Every graph not containing a ray linked disjointly to infinitely many vertices of infinite degree has an unfriendly partition.

## 2 Definitions and statement of main result

Recall that a **cofinal** subset of an ordered set \( A \) is a subset \( B \) such that for every \( a \in A \) there is a \( b \in B \) such that \( a \leq b \). The **cofinality** of an ordinal \( \alpha \) is the smallest ordinal \( \delta \) which is the order type of a cofinal subset of \( \alpha \). The cofinality of an ordinal is always a cardinal, but we will not need to make use of this fact.

For general graph-theoretic terminology we refer the reader to [2]. Given a graph \( G \) and a vertex \( x \in V(G) \), we let \( d_G^C(x) \) denote the number of neighbours of \( x \) in a subset \( U \subseteq V(G) \). For convenience, if \( C \) is a subgraph of \( G \), or a set of subgraphs of \( G \), or a set of sets of subgraphs of \( G \), we will simply write \( d_C^G(x) \) — to avoid more cumbersome notation of the form \( d_{V(G \cup C)}(x) \) — for the number of neighbours of \( x \) (nested) in \( C \).

A **partition** of a set \( V \) or a graph \( G = (V, E) \) is a function \( \pi : V \to \{0, 1\} \). For a partition \( \pi \) of \( G \) and a vertex \( x \in V(G) \), we say that a neighbour \( y \) of \( x \) is an **opponent** (respectively, a **friend**) of \( x \) in \( \pi \) if \( \pi(y) \neq \pi(x) \) (resp. \( \pi(y) = \pi(x) \)). We write \( a_{\pi}(x) \) for the number of opponents of \( x \) in \( \pi \). Moreover, if \( U \) is a subset of \( V(G) \) or a subgraph of \( G \), then we write \( a_{\pi}(x, U) \) for the number of opponents of \( x \) in \( \pi \) that lie in \( U \). A vertex is **happy** in a partition \( \pi \) if it has at least as many opponents as it has friends. In particular, if a vertex \( x \) has infinite degree then it is happy in \( \pi \) if and only if \( d(x) = a_{\pi}(x) \). A partition is **unfriendly** if every vertex is happy in it, and it is **unfriendly for a vertex set** \( Y \) if every vertex in \( Y \) is happy.

A graph \( G \) is **pre-partitionable** if for every \( U \subseteq V(G) \) and every partition \( \pi \) of \( U \) there is a partition \( \pi' \) of \( G \) extending \( \pi \) so that every vertex in \( V(G \setminus U) \) is happy in \( \pi' \). In particular, since we can choose \( U \) to be the empty set, every pre-partitionable graph has an unfriendly partition. Clearly, every finite graph is pre-partitionable: given \( U \) and \( \pi \), choose \( \pi' \) so as to maximize the number of edges incident with \( V(G \setminus U) \) whose endvertices lie in different partition classes.

Schmidt [3] observed that it is possible to construct all rayless graphs by a recursive, transfinite procedure, starting with the class of finite graphs and then, in each step, glueing graphs constructed in previous steps along a common finite vertex set, to obtain new rayless graphs. We are going to generalise Schmidt’s construction by replacing the class of finite graphs by larger classes.

In order to do so, we call a class \( U \) of graphs **finitely closed** if it is closed under taking finite disjoint unions and also under adding finitely many new vertices and joining them arbitrarily to each other and to the old vertices. Starting with any finitely closed class \( U \) it is possible to recursively construct a larger class [17] as follows.
Definition 2.1. Let \( \mathcal{U} \) be a finitely closed class of graphs. For every ordinal \( \mu \) we define recursively a class \( \mathcal{U}(\mu) \):

- \( \mathcal{U}(0) := \mathcal{U} \); and

- if \( \mathcal{U}(\lambda) \) is defined for every \( \lambda < \mu \), we include a graph \( G \) in \( \mathcal{U}(\mu) \) if it has a finite vertex set \( S \) such that for every component \( C \) of \( G - S \) there is an ordinal \( \lambda < \mu \) such that \( \mathcal{U}(\lambda) \) contains \( C \).

The closure \( \overline{\mathcal{U}} \) of \( \mathcal{U} \) is the union of the classes \( \mathcal{U}(\lambda) \) for all ordinals \( \lambda \). For a graph \( G \) in \( \overline{\mathcal{U}} \) we define its rank to be the smallest ordinal \( r_\mathcal{U}(G) = r(G) \) such that \( \mathcal{U}(r(G)) \) contains \( G \).

The prime example of a finitely closed class is the class \( \mathcal{F} \) of finite graphs, and the rayless graphs are precisely those in \( \mathcal{F} \). The locally finite graphs clearly do not form a finitely closed class; but the graphs with only finitely many vertices of infinite degree do, and so do the graphs with only finitely many vertices of finite degree. Another class, which contains all these, will be defined in Section 5.

We note two properties of the above construction that are not hard to prove.

Lemma 2.2. Let \( G \) be a graph in \( \overline{\mathcal{U}} \) for some finitely closed class \( \mathcal{U} \) of graphs, and let \( S \) be a finite vertex set so that \( r(C) < r(G) \) for every component \( C \) of \( G - S \).

(i) If \( C_1, \ldots, C_n \) are components of \( G - S \) then \( r(G[S \cup \bigcup_{i=1}^n C_i]) < r(G) \).

(ii) If \( S \) is \( \subseteq \)-minimal with the property that \( r(C) < r(G) \) for each component \( C \) of \( G - S \) then each vertex in \( S \) has infinite degree.

Proof. To see (i), we show that \( r(G[S \cup \bigcup_{i=1}^n C_i]) \leq \max_i r(C_i) \) which is by assumption smaller than \( r(G) \). Suppose first that all \( C_i \) have rank 0, i.e. lie in \( \mathcal{U} \). Then so does \( G[S \cup \bigcup_{i=1}^n C_i] \) as \( \mathcal{U} \) is finitely closed. Otherwise, for every \( 1 \leq i \leq n \) with \( r(C_i) > 0 \) let \( S_i \) be a finite vertex set in \( C_i \) such that the rank of every component of \( C_i - S_i \) is less than \( r(C_i) \). Then \( S \cup \bigcup_i S_i \) is a finite set witnessing the fact that \( r(G[S \cup \bigcup_{i=1}^n C_i]) \leq \max_i r(C_i) \).

For (ii), note that if \( x \in S \) has finite degree then the components of \( G - (S \setminus \{x\}) \) are precisely the components of \( G - S \) that are not adjacent to \( x \), plus one new component obtained by merging \( x \) and the finitely many components of \( G - S \) adjacent to \( x \). By an argument similar to that of (i), the rank of this new component is at most the maximum of the ranks of the components that got merged. But then \( r(C) < r(G) \) for every component \( C \) of \( G - (S \setminus \{x\}) \), contradicting the minimality of \( S \) with this property.

Here is the main result of this paper:

Theorem 2.3. If \( \mathcal{U} \) is a finitely closed class of graphs and every graph in \( \mathcal{U} \) is pre-partitionable, then every graph in \( \overline{\mathcal{U}} \) is pre-partitionable.

As every finite graph is pre-partitionable and every pre-partitionable graph has an unfriendly partition, Theorem 2.3 with \( \mathcal{U} = \mathcal{F} \) implies Theorem 1.1.

We prove Theorem 2.3 in Section 6. In Section 4 we use it to prove that a considerably larger class than the rayless graphs have unfriendly partitions.
3 Proof of the main result

We now prove Theorem 2.3.

Proof of Theorem 2.3 Let $G = (V, E)$ be a graph in $\mathcal{G}$. We perform transfinite induction on $r(G)$. If $r(G) = 0$ then $G$ is pre-partitionable by assumption, so suppose that $r(G) = \alpha > 0$ and the assertion is true for all ordinals $\beta < \alpha$. Let $S \subseteq V(G)$ be a minimal separator such that $r(C) < \alpha$ for every component of $G - S$, and let $C$ be the set of those components. We will prove that $G$ is pre-partitionable by a second transfinite induction on $\kappa := |C|$. By Lemma 2.2, $\kappa$ must be infinite. We will treat the first step of the induction (i.e. the case $\kappa = \omega$) more or less in the same way as the induction step; so assume from now on that either $\kappa = \omega$ or $\kappa > \omega$ and, by the induction hypothesis, any subgraph of $G$ spanned by $S$ and less than $\kappa$ elements of $C$ is pre-partitionable; by Lemma 2.2 we can assume this even if $\kappa = \omega$.

Let $S_0$ be the set of vertices $s \in S$ for which there is a subset $C_s$ of $C$ of cardinality less than $\kappa$ with $d_{C_s}(s) = d(s)$; then let $S_1 := S \setminus S_0$. Let $X_0 := \bigcup_{s \in S_0} C_s$, and assume, without loss of generality, that

$$N(s) \subseteq S \cup \bigcup X_0$$

for every $s \in S_0$ with $d(s) < \kappa$, \((1)\)

where $N(s)$ denotes the set of vertices adjacent with $s$.

We claim that

$$\text{if } s \in S_1 \text{ then either } d(s) = \kappa \text{ or } d(s) \text{ is a singular cardinal of cofinality } \kappa. \tag{2}$$

Indeed, all vertices in $S$ with degree less than $\kappa$ lie in $S_0$, thus $d(s) \geq \kappa$. If $s$ has degree $\lambda > \kappa$ then $\lambda$ is a singular cardinal of cofinality at most $\kappa$ as it is the sum of $\kappa$ cardinals smaller than $\lambda$, namely of $d_{C_s}(s)$ for all $C \in C$ (we know that $d_{C}(s) < \lambda$ because $s \not\in S_0$). It remains to verify that the cofinality of $\lambda$ is not smaller than $\kappa$.

Suppose, on the contrary, that $\lambda$ is the sum of cardinals $\beta_\alpha$, $\alpha < \gamma$, where $\gamma < \kappa$ and every $\beta_\alpha$ is smaller than $\lambda$. Then for every $\alpha$ there is a component $C_\alpha \in C$ such that $d_{C_\alpha}(s) \geq \beta_\alpha$; for if not, then $\lambda \leq |C| \cdot \beta_\alpha < \lambda$, a contradiction. But then, the components $C_\alpha, \alpha < \gamma$ contain $\lambda = d(s)$ many of the neighbours of $s$, and as $\gamma < \kappa$ this contradicts $s \not\in S_0$.

It is possible to partition $C \setminus X_0$ into $\kappa$ finite sets $X_\beta, \beta < \kappa$ so that

$$\text{for every } s \in S_1 \text{ and every subset } Z \text{ of } \{X_\beta\}_{\beta < \kappa} \text{ with } |Z| = \kappa \text{ there holds } d_Z(s) = d(s). \tag{3}$$

Indeed, given $s \in S_1$, it is easy, in both cases of (2), to find a sequence $(C_\beta^{s})_{\beta < \kappa}$ of distinct elements of $C$ such that for every subset $Z'$ of $(C_\beta^{s})_{\beta < \kappa}$ with $|Z'| = \kappa$ there holds $d_{Z'}(s) = d(s)$. Furthermore, let $(D_\beta)_{\beta < \lambda}$ be a sequence indexed by some ordinal $\lambda \leq \kappa$ containing all elements $D \in C$ that are not in a sequence $(C_\beta^{s})_{\beta < \kappa}$ for any $s \in S_1$. Depending on whether $\kappa = \omega$ or not, we now define the $X_\beta$, $i < \kappa$, recursively as follows. If $\kappa > \omega$, then for every $s \in S_1$ we let $C_{m_i}$ be the first member of $(C_\beta^{s})_{\beta < \kappa}$ that is not an element of $\bigcup_{\beta < \lambda} X_\beta$, and let $X_\beta := \{D_i\} \cup \{C_{m_i}^s \mid s \in S_1\}$ if $i < \lambda$ and $X_\beta := \{C_{m_i}^s \mid s \in S_1\}$ otherwise. If $\kappa = \omega$, we define $X_\beta$ in a slightly different way. Namely, we let $X_\beta := \{D_1\} \cup \bigcup_{s \in S_1} C_{i}^s$ if $i < \lambda$ and $X_\beta := \bigcup_{i \in S_1} C_{i}^s$ otherwise, where $C_{i}^s$ is a finite
subset of \( \{ C_{\beta}^s \}_{\beta < \kappa} \setminus \bigcup_{\beta < \kappa} X_\beta \) containing \( C_{\alpha_0}^s \), such that \( d_{C_{\beta}^s}(s) > d_S(s) + d_{X_\beta}(s) \); easily, such a \( C_{\beta}^s \) exists by (2) and the definition of \( S_1 \). It is now easy to check that (3) is indeed satisfied, and moreover for the case \( \kappa = \omega \) we have in addition, for every \( Z \) and every \( s \) as in (3), that

\[
d_X(s) > d_S(s) + d_{X_\alpha}(s) \quad \text{for every } X \in Z.
\]

Now let \( U \subseteq V \), and let \( \pi_U \) be any partition of \( U \). We have to show that there is a partition \( \chi \) of \( V \) extending \( \pi_U \) that is unfriendly for \( V \setminus U \).

For every \( \beta < \kappa \), let \( G_{\beta} \) be the subgraph of \( G \) spanned by \( S \) and all components in \( X_0 \cup X_{\beta} \). Note that \( r(G_{\beta}) \leq r(G) \) for every \( \beta \), and \( G_{\beta} \setminus S \) has less components than \( G \setminus S \) because \( |X_0| < \kappa \) and \( |X_{\beta}| < \omega \). Thus by our second induction hypothesis—or by our first induction hypothesis if \( r(G_{\beta}) < r(G) \)—there is a partition \( \rho_{\beta} \) of \( G_{\beta} \) that extends \( \pi_U \) \( \cap \) \( (V(G_{\beta}) \setminus U) \) and is unfriendly for \( V(G_{\beta}) \setminus U \).

Define the \( X_0 \)-stamp of \( \rho_{\beta} \) to be the set of vertices \( s \in S_0 \) that are given \( d(s) \) opponents within \( \bigcup X_0 \) by \( \rho_{\beta} \), i.e. those for which \( a_{\rho_{\beta}}(s, \bigcup X_0) = d(s) \) holds. Since \( S \) is finite, there is a partition \( \rho_S \) of \( S \), a subset \( S' \subseteq S_0 \), and a subsequence \( (\rho_{\beta_0})_{\beta_0, \beta \leq \kappa} \) of \( (\rho_{\beta})_{\beta < \kappa} \) with \( |J| = \kappa \) such that \( \rho_S \setminus S = \rho_S \) and the \( X_0 \)-stamp of \( \rho_S \) is \( S' \) for every \( \alpha \in J \). Using this subsequence, we will now construct a partition \( \tau \) of \( G \) that is unfriendly for all but finitely many of the vertices in \( V \setminus U \), and later modify \( \tau \) to obtain the desired partition \( \chi \) that is unfriendly for \( V \setminus U \).

For every \( \alpha \in J \), we partition \( X_\alpha \) as in \( \rho_\alpha \); formally, for every vertex \( x \) in \( \bigcup X_\alpha \), let \( \tau(x) := \rho_\alpha(x) \). We proceed similarly with \( X_0 \); we pick some \( \alpha_0 \in J \) and then for every vertex \( x \) in \( \bigcup X_0 \), we let \( \tau(x) := \rho_{\alpha_0}(x) \). In order to partition the remaining vertices of the graph, we define the partition \( \pi_{U \cup S} := \pi_U \cup \rho_S \); this is well-defined since \( \rho_S \) is by construction compatible with \( \pi_U \). Now for every \( \beta \in \kappa \setminus J \) we pick a partition \( \rho_\beta'(\beta) \) of the graph \( G_{\beta}' := G[S \cup (\bigcup X_{\beta})] \) that extends \( \pi_{U \cup S} \setminus G_{\beta}' \) and is unfriendly for \( V(G_{\beta}') \setminus (U \cup S) \)—such a partition exists by our first inductive hypothesis, since \( r(G_{\beta}') < r(G) \)—and again we partition the vertices in \( \bigcup X_{\beta} \) according to \( \rho_\beta'(\beta) \). For every vertex \( x \) in \( \bigcup X_{\beta} \), we let \( \tau(x) := \rho_\beta'(\beta)(x) \).

By construction, \( \tau \) extends \( \pi_U \). Moreover, it is straightforward to check that

\[
\tau \text{ is unfriendly for } V \setminus (S_1 \cup U).
\]

Since the \( \rho_\alpha \) have the same \( X_0 \)-stamp for every \( \alpha \in J \), it follows that

\[
\text{for every } s \in S_0, \text{ either } a_s(s, \bigcup X_0) = d(s) \text{ or for every } \alpha \in J \text{ there holds } a_s(s, \bigcup X_\alpha) = d(s) \text{ (or both).}
\]

Let \( F \subseteq S_1 \) be the set of vertices of \( V \setminus U \) that are not happy in \( \tau \). We claim that

\[
\text{for every } r \in F \text{ there holds } d(r) = \kappa.
\]

Indeed, pick any \( r \in S_1 \setminus U \) with \( d(r) > \kappa \). We need to show that this choice implies \( r \notin F \). By the definition of \( S_0 \) and since \( r \notin S_0 \), \( r \) cannot have full degree in \( \bigcup X_0 \), i.e. \( \delta := d_{X_\alpha}(d) < d(r) \). Define \( Z' \) to be the set of those \( X_\alpha \), \( \alpha \in J \), for which \( d_{X_\alpha}(r) \leq \delta \). Since \( |Z'| \leq |J| = \kappa < d(r) \) and \( \delta < d(r) \), we obtain that \( d_{Z'}(r) \leq \kappa \cdot \delta < d(r) \). Hence, from (3) it follows that \( |Z'| < \kappa \) and
thus the set \( Z := \{ X_\alpha : \alpha \in \mathcal{J} \} \setminus Z' \) has cardinality \( \kappa \). Using (8) again yields 
\[ d_Z(r) = d(r). \]

Now consider one such \( X_\alpha \in Z \). Recall that \( r \) is happy in the partition \( \rho_\alpha \) of the graph \( G_\alpha \), which we defined to be the induced subgraph on \( S \) together with all components in \( X_0 \cup X_\alpha \). Since \( d_{X_\alpha}(r) > \delta = d_{X_\alpha}(r) \), this means that \( r \) has, with respect to \( \rho_\alpha \), \( d_{X_\alpha}(r) \) opponents in \( U \cup X_\alpha \). Since \( \tau \) and \( \rho_\alpha \) coincide on \( U \cup X_\alpha \) by the definition of \( \tau \), this implies that \( \tau \) is unfriendly for \( V_{X_\alpha} \) and is therefore happy. Since \( F \) comprises unhappy vertices, we have proved (7).

We claim that \( F \) is empty if \( \kappa = \omega \). Indeed, if \( \kappa = \omega \) then every vertex \( r \) in \( F \) has degree \( \omega \) by (7) and so \( d_f(r) \) is finite. Thus by (8) and the fact that \( \tau \) coincides with the partition \( \rho_\alpha \) of \( G_\alpha \), which is unfriendly for \( V(G_\alpha)\setminus U \), \( \tau \) gives an opponent in \( X_\alpha \) for every \( \alpha \in \mathcal{J} \). But then \( \tau \) has \( |\mathcal{J}| = \kappa = \omega \) opponents in \( \tau \), contradicting the assumption that \( r \in F \). Thus \( F = \emptyset \) if \( \kappa = \omega \), which means that \( \tau \) is unfriendly for \( V \setminus U \) and we are done. So we may from now on assume that
\[ \kappa \text{ is an uncountable cardinal.} \tag{8} \]

Denote by \( \tau' \) the partition obtained from \( \tau \) by flipping \( F \), i.e. by moving each vertex in \( F \) from its partition class in \( \tau \) to the other partition class (formally, by changing the image under \( \tau \) of every vertex in \( F \)). Then, \( \tau' \) is unfriendly for \( S \setminus U \), as all vertices in \( S \) have infinite degree by Lemma 22, but there might be vertices in the rest of the graph that were made unhappy by flipping \( F \). It follows from (8) and (9) that the set \( \mathcal{Y} \) of elements of \( C \setminus X_0 \) (we will turn our attention to \( X_0 \) later) that contain vertices that are unhappy in \( \tau' \) has cardinality less than \( \kappa \), because each vertex in \( F \) had less than \( \kappa \) opponents in \( \tau \).

We now modify \( \tau' \) within \( \mathcal{Y} \) to obtain a new partition \( \phi \) of \( G \) that is unfriendly for \( V \setminus (V(\bigcup X_0) \cup U) \). For every component \( C \in \mathcal{Y} \), let \( U' := (U \cap V(C)) \cup S \), and pick a partition \( \phi_C \) of \( G[S \cup V(C)] \) that extends \( \tau' \setminus U' \) and is unfriendly for \( V(C) \setminus U' \); such a partition exists by our first induction hypothesis as \( r(C) < r(C) \). Then, for every \( x \in V(C) \) put \( \phi(x) := \phi_C(x) \). Vertices that are not contained within \( \mathcal{Y} \) we leave unchanged: for every \( x \in V \setminus V(\bigcup \mathcal{Y}) \) put \( \phi(x) := \tau'(x) \).

We claim that
\[ \phi \text{ is unfriendly for } V \setminus (V(\bigcup X_0) \cup U). \tag{9} \]

Indeed, \( \phi \) is by construction unfriendly for \( V \setminus (V(\bigcup X_0) \cup U \cup S) \). To see that it is unfriendly for \( S \setminus U \) as well, recall that \( \tau' \) was unfriendly for \( S \setminus U \), and suppose there is an \( s \in S \) unhappy in \( \phi \). Since \( s \) was happy in \( \tau' \), it follows that \( s \) has \( d(s) \) many neighbours within \( \mathcal{Y} \), which puts \( s \) in \( S_0 \) as \( |\mathcal{Y}| < \kappa \). But then by (8) if \( s \) is not given \( d(s) \) opponents in \( X_0 \) by \( \tau' \), and thus also by \( \phi \), then \( s \) is given \( d(s) \) opponents in each of the \( \kappa \) many \( X_\alpha \) with \( \alpha \in \mathcal{J} \) that do not contain a component in \( \mathcal{Y} \), a contradiction. This establishes Claim (9).

Finally, we turn our attention to the unhappy vertices in \( \bigcup X_0 \). These vertices were happy in \( \tau \) and thus had an opponent in \( \tau \) that is lost in \( \phi \), which means that they are adjacent to a vertex in \( F \). Observe that
\[ \gamma := \max\{\omega, \max_{r \in F} \alpha(r, V(\bigcup X_0))\} < \kappa. \tag{10} \]
Indeed, recall that $\omega < \kappa$ by $\square$. Moreover, by the definition of $S_1$ each vertex $r \in F \subseteq S_1$ has less than full degree in $V(\bigcup X_0)$, and thus $a_\tau(r, V(\bigcup X_0)) \leq d_{X_0}(r) < d_G(r)$. Since $d_G(r) = \kappa$ by $\square$ the claim follows.

Let $H := G[\bigcup X_0] \cup S$ and define $S'_0$ to be the set of vertices $s \in S_0$ with $a_\phi(s, V(\bigcup X_0)) < d_G(s)$. Putting $\bar{U} := (U \cap V(H)) \cup S'_0 \cup S_1$ we shall find a partition $\rho$ of $H$ with the following properties.

(i) $\rho$ is unfriendly for $V(H) \setminus \bar{U}$.

(ii) $\rho$ extends $\phi \upharpoonright \bar{U}$; and

(iii) for every $x \in V(H)$ if $d_H(x) > \gamma$ then $\rho(x) = \phi(x)$.

Intuitively, what $\rho$ accomplishes is to repartition the vertices in $X_0$ and part of the vertices in $S_0$ in such a way that firstly, every vertex in $X_0$ or $S$ is made happy, and secondly, any vertex in $S_0$ whose partition class we changed has relatively small degree. The latter condition on the degree will then help make sure that the happiness of the vertices in $\bigcup X_0$ is not affected by the repartitioning imposed by $\rho$.

Before we construct $\rho$ let us check that it would indeed allow us to finish the proof. For this, we modify $\phi$ within $H$ according to $\rho$ to obtain a new partition $\chi$ of $G$: for every $x \in V(H)$ let $\chi(x) := \rho(x)$ and for every $x \in V \setminus V(H)$ let $\chi(x) := \phi(x)$. The following table summarises the definitions of some of the partitions of $G$ we have defined so far, and indicates which vertices are happy in each partition.

|              | $X_0 \setminus X_0$ | $S_0$ | $F$ | $S_1 \setminus F$ | composed from $\rho_3$ | obtained from $\tau$ by flipping $F$ | obtained from $\tau'$ by changes in $\mathcal{V}$ | obtained from $\phi$ by changes in $H$ |
|--------------|---------------------|-------|-----|-------------------|------------------------|--------------------------------------|--------------------------------------|--------------------------------------|
| $\tau$       | $\square$           | $\square$ | $\times$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |
| $\tau'$      | $\square$           | $\square$ | $\times$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |
| $\phi$       | $\square$           | $\square$ | $\times$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |
| $\chi$       | $\square$           | $\square$ | $\times$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |

We claim that $\chi$ is unfriendly for $V \setminus U$. Indeed, any vertex $x \in V(\bigcup X_0) \setminus U$ is clearly happy by condition $\square$. For a vertex $s \in S \setminus U$ we distinguish three cases. If $s \in S_1$ then $s$ has less than full degree in $\bigcup X_0$ by the definition of $S_1$, and thus by $\square$, $s$ is happy in $\chi$ as it was happy in $\phi$. If $s \in S'_0$ then, by the definition of $S'_0$ and $\square$, it had $d_G(s)$ opponents outside $\bigcup X_0$ in $\phi$. As $\phi$ and $\chi$ coincide outside $\bigcup X_0$ and as $\phi(s) = \chi(s)$ by $\square$, the vertex $s$ is happy in $\chi$. Finally, if $s \in S_0 \setminus S'_0$ then $\chi(s) = \rho(s)$. As $s$ is happy in $\rho$ (within $H$) by $\square$ and as $\chi$ coincides with $\rho$ on $H$, we find that $s$ is happy in $\chi$ as well (note that $d_H(s) = d_G(s)$ since $s \in S_0$). It remains to check that every vertex in $V \setminus (S \cup V(\bigcup X_0) \cup U)$ is happy too. So consider a vertex $x$ in $\bigcup X_0 \setminus U$ for some ordinal $\alpha$. Such an $x$ was happy in $\phi$, but since we changed the partition of $S$ we may have made it unhappy in $\chi$. This is however not the case: if $s \in S$ and $\phi(s) \neq \chi(s)$, then by $\square$ and $\square$, we have $s \in S_0$ and $d_G(s) = d_H(s) \leq \gamma < \kappa$, where the last inequality is $\square$. Thus by $\square$, $s$ has all its neighbours in $\bigcup X_0$, which means that $s$ is not a neighbour of $x$. In conclusion, $x$ is still happy in $\chi$ and this completes the proof that $\chi$ is unfriendly for $V \setminus U$.

To finish the proof of the theorem we still need to construct the partition $\rho$. Define $A$ to be the set of all vertices $a$ in $H \setminus \bar{U}$ with $d_H(a) \leq \gamma$. Denote by $K$ the union of the vertex sets of all the components of $H[A]$ that contain an
unhappy vertex (with respect to φ). Observe that such an unhappy vertex must have been an opponent in τ of some vertex in F. Thus by (10) there are at most γ components of this kind, and as each of them has at most γ vertices we obtain

\[ |K| \leq \gamma. \] (11)

By our second induction hypothesis the graph H is pre-partitionable, thus there is a partition ρ of H extending φ \restriction U \cup (V(H) \setminus K) such that every vertex in K \setminus \tilde{U} is happy. Clearly, ρ satisfies (10) and (11).

To see that every vertex x in \( V(H) \setminus (K \cup \tilde{U}) \) is happy too, which would complete the proof that (11) is satisfied as well, we note that ρ differs from φ only within K, and distinguish two cases. If \( d_H(x) \leq \gamma \), then since \( x \notin K \), its neighbourhood \( N_H(x) \) does not meet K by the definition of A, thus φ and ρ coincide in \( N_H(x) \). By the definition of K it follows that x was happy in φ, thus it is also happy in ρ as its neighbourhood was not repartitioned. If, on the other hand, \( d_H(x) > \gamma \), then x was happy in φ because \( |F| \) is finite, γ is infinite, and x was happy in τ. But then x is happy in ρ by (11) since only vertices in K were repartitioned while changing φ to ρ. \( \square \)

4 More graphs with unfriendly partitions

In the rest of the paper we shall strengthen Theorem 1.1 by applying Theorem 2.3 to a larger finitely closed class than just \( \mathcal{F} \). A proof of Theorem 1.2 will follow as a corollary.

Given a graph \( G = (V, E) \), let \( V_\infty \) be the set of all vertices of infinite degree, and denote by \( V^* \) the set of those vertices in \( V_\infty \) that have only finitely many neighbours in \( V_\infty \). Let \( \mathcal{W} \) be the class of countable graphs G such that \( V^*(G) \) is finite. In particular, \( \mathcal{W} \) contains all countable graphs G for which \( V_\infty(G) \) or \( V(G) \setminus V_\infty(G) \) is finite. Note that \( \mathcal{W} \) also contains all uncountable graphs G for which \( V_\infty(G) \) is finite, since deleting \( V_\infty(G) \) shows that G has rank 1 in \( \mathcal{W} \). Clearly, \( \mathcal{W} \) is finitely closed. We claim that

**Theorem 4.1.** Every graph in \( \mathcal{W} \) is pre-partitionable. In particular, every such graph has an unfriendly partition.

In order to prove this we will need the following lemma from [14] Lemma 3].

**Lemma 4.2.** Let \( G = (V, E) \) be a countable graph and let \( U \) be a subset of V such that only finitely many vertices in \( V \setminus U \) have infinite degree (in G). Then for every partition \( \pi \) of \( G[U] \) there exists a partition \( \pi' \) of G that extends \( \pi \) and which is unfriendly for \( V \setminus U \).

**Proof of Theorem 4.1.** Consider a graph G in \( \mathcal{W} \). We will prove that G has an unfriendly partition. It is easy to modify this proof in order to show that G is pre-partitionable. The theorem then follows from Theorem 2.3.

First, let us construct an unfriendly partition \( \pi \) of \( G[V_\infty \setminus V^*] \). Observe that \( |V^*| < \infty \) implies that every vertex in \( G[V_\infty \setminus V^*] \) has infinite degree. Pick a sequence \( (v_i)_{i \in \mathbb{N}} \) in which every vertex in \( V_\infty \setminus V^* \) appears infinitely often. We go through this sequence, and if \( \pi(v_i) \) has not been defined yet we set \( \pi(v_i) = 0 \). Otherwise, we choose a neighbour \( y \in V_\infty \setminus V^* \) of \( v_i \) with \( \pi(y) \) still undefined and set \( \pi(y) := 1 - \pi(v_i) \). It is now easy to check that \( \pi \) is indeed unfriendly.
Next, Lemma 4.2 yields a partition $\pi'$ of $G$ extending $\pi$ so that $\pi$ is unfriendly for $V(G) \setminus (V_\infty \setminus V^*)$. Since every vertex in $V_\infty \setminus V^*$ already had infinitely many opponents in $\pi$, it follows that $\pi'$ is unfriendly for all of $V(G)$. \hfill \Box

The countable graphs in $\W$ can be characterised as follows.

**Proposition 4.3.** A countable graph $G$ lies in $\overline{W}$ if and only if it contains no comb with all teeth in $V^*(G)$.

**Proof.** Suppose there are graphs in $\overline{W}$ that contain a comb with all teeth in $V^*(G)$. Then, there is such a graph $G$ that has minimal rank among all those graphs; let $C$ be a comb in $G$ with all its teeth in $V^*(G)$. Clearly, $G$ does not have rank 0, so there is a finite set $S$ of vertices such that all components of $G - S$ have rank smaller than $r(G)$. But one of the components contains a tail of $C$, contradicting the minimality of $r(G)$.

Conversely, let $G$ be a countable graph not in $\overline{W}$. Then there is a component $C_0$ of $G$ that does not lie in $\overline{W}$ (otherwise $S = \emptyset$ is a separator as in Definition 2.1 showing that $G \in W$). Since $C_0 \notin \W$ although $C_0$ is countable, there is a vertex $v_0 \in V^*$ in $C_0$. At least one component $C_1$ of $C_0 - v_0$ is not in $\overline{W}$, and thus contains a vertex $v_1 \in V^*(G)$. Let $P_1$ be a $v_0$-$v_1$ path in $C_1 \cup \{v_0\}$. Now recursively for $i = 1, 2, \ldots$, let $C_i$ be a component of $C_{i-1} - P_{i-1}$ that is not in $\overline{W}$, let $v_i$ be a vertex of $V^*$ in $C_i$, and let $P_i$ be a $V(P_{i-1} \cap C_{i-1})$-$v_i$ path in $G[C_i \cup P_{i-1}]$. It is not hard to see that $\bigcup_{i<\omega} P_i$ is a comb with teeth $v_0, v_1, \ldots$ in $V^*$.

As remarked earlier, the class $\mathcal{U}$ of (countable or uncountable) graphs that have only finitely many vertices of infinite degree is contained in $\overline{W}$. And as in the proof of Proposition 4.3 we see that any graph not in $\overline{U}$ contains a comb whose leaves all have infinite degree; let us call such a comb a *brush*. Graphs not containing a brush thus lie in $\overline{U} \subseteq \overline{W} = \overline{W}$, and we obtain Theorem 1.2 as a corollary of Theorem 4.1.

**Corollary 4.4.** Every graph not containing a brush has an unfriendly partition.

**Acknowledgement**

We would like to thank Matt DeVos for inspiring discussions on this subject.
