Abstract

This study aims at the assessment of the impacts of artisanal refining of crude on soil and water quality in parts of Okrika and Ogu-Bolo areas of Rivers State, Nigeria. Standard sampling methods were used in the study. A total number of sixteen (16) sampling points were selected using random sampling techniques for the water points and soil samples within Ogu-Bolo and Okrika. Water and soil samples were analyzed in the laboratory using standard methods. The ArcGIS version 10.3, ENVI version 4.7, Surfer 10, SPSS 22 and Microsoft Enterprise were used for the interpretation. The Digital Elevation Model (DEM) was created from the elevation data obtained from Short Radar Thematic Mapper (SRTM) satellite image and contour extracted from the topographic map. The influence of the soil type, slope, flow accumulation and flow direction of the study area was used to delineate the level of contaminant plume. This was generated from the DEM using the ArcGIS 10.3 3-D analyst tool function. A water Quality index rating of 1 was measured in the studied area which is an indication that the water is very bad. Also, the physio-chemical analysis on soil and water revealed poor water and soil quality. Water analysis showed high concentration of Fe and Zn which made the water in such area unsuitable for drinking. Also, the soil samples recorded high levels of crude content from 1m, with concentration reducing with depth up to 3m. A general contamination map of Okrika/Ogu-Bolo was modelled, indicating the contamination rating of total land mass of the study area, with 23.59km (5.71%) rated very good, while 85.65km (20.71%) were rated good. Also, 140.37km (33.95%) had only one or two contaminants giving moderate level of contamination while 112.56km (27.22%) recorded bad level of contamination, with 51.29km (12.40%) of the total land mass having very bad contamination record. Water quality assessment should be carried out regularly to determine any future pollution of the water. It is recommended that artisanal refining activities in the area should be discouraged to avoid further contamination in the area.

Keywords: Aquifer vulnerability, plume, contaminant, water quality, artisanal refining, soil

Citation to This Article: Nwankwoala HO, Harry MT, Amangabara GT, Warmate T. Impacts of Artisanal Refining Activities on Soil and Water Quality in Parts of Okrika and Ogu-Bolo Areas of Rivers State, Nigeria. Journal of Scientific Achievements, September 2017; 2 (9): 13-19.

1. INTRODUCTION

Contamination of groundwater is on a steady rise particularly in our urban cities where so many industrial activities are carried out, increase in population, land that are used for commercial agriculture, poor sanitary system and other factors causing environmental degradation (Amangabara and Njoku, 2012; Nwankwoala and Mzaga, 2017). The contaminated Groundwater unlike surface water contamination is considered a more difficult problem because of the difficulty in its early detection and skill required for prediction of its rate and path of movement (Nwankwoala & Nwagboegwu, 2012; Nwankwoala and Ngah, 2013) and the extent of the impact. Also, to determine the concentration of these contaminants in the groundwater will depend on the quantity and nature of the elements that are found in it, which can be brought in naturally or through human actions and spread across the geological stratification of the area.

Petroleum refining is responsible for the inputs of gaseous, solid and liquid wastes into the environment (Avwiri and Ononugbo, 2012). Some of these wastes are said to contain poisonous substances, and if brought into the environment, they will possibly cause damage to the environment, constantly staying deposits, found in living things could build-up in adipose tissues and also move up the trophic web or chain (Eluozo, 2013). In Nigeria, the Niger Delta region is believed to be the centre of natural and crude oil with numerous networks of product pipelines (both on and under the earth surface) completely across the entire region, and has resulted in the destruction of oil and gas pipelines, refining these products locally and the related environmental dangers which are obvious societal problems.
In the study area, some hand dug wells and deep wells (boreholes) were abandoned due to variations of the physico-chemical properties of groundwater. Also, reports of oil spills and complaints associated with groundwater contamination have increased in Ogu-Bolo and Okrika. This study therefore, evaluates the vulnerability of the groundwater within the study area.

2. THE STUDY AREA

The study area (Figure 1) is located in the Okrika, and Ogu-Bolo Local Government Area of Rivers State. It is readily accessible by a network of roads and footpaths and accessible to ships, boats, and canoes through the Bonny River and its tributaries.

The study area is confined within the humid-hot equatorial climate, (Ojo, 1977). The average annual temperature is between 180°C to 220 °C with annual range of about 200°C. It is known for having two main seasons, the dry season and the wet season. The dry season begins from November and ends in March, while the wet stretches from mid-march to October. Fresh water is generally supplied by heavy precipitation estimated to have met annual rainfall above 2600mm (Ojo, 1977; Nwankwoala et al., 2013). The mean annual rainfalls within the past ten years, from 1997 to 2007, in Port Harcourt have shown notable variation. However, the maximum rainfall recorded within the years under review was in September 2006, with the mean annual rainfall within the periods (1997-2007) estimate to be 4455mm. The peaks of the rains occur in the months of June, July, September and October.

The most significant factor that influences rainfall within this area is the tropical marine air mass, moisture. Laden air blows from the sea at least for ten months in a year that is, stretching from February to November. The counter air mass known as the tropical continental air mass blows from the Sahara Desert with dry and dusty characteristics. It is usually experienced in the place of study between December and January. The relative humidity is very high all through the year, and it is greater than 80% (Offodile, 2002). Bonny River and its tributaries and the creeks are accountable for the drainage around the deltaic plain belt area. The dockyard creek in the south, Amadi and Okpoka creeks in the east the channel of Bonny River (Port Harcourt Harbour) by the west drain the area. These creeks flow in the N-S direction into the bonny river, which eventually flow to the west. Each of the creeks that border Port Harcourt area can be subdivided into three sections, the head water are usually fresh water streams, the down strems which are saline and the brackish water area in between them.

3. METHODS OF STUDY

A total number of sixteen (16) sampling points were selected using random sampling techniques used in selecting the water points (wells, boreholes) and soil samples within Ogu- Bolo and Okrika. The map required for this study was acquired with the use of Geographic Information System (GIS). Table 1 depicts the coordinates of location of soil samples while Table 2 shows the water sample coordinate locations.

To delineate the study area, the administrative map that covers the area of study was geo-coded with a minimum Root Mean Square (RMS) error of 0.00005. Subsequently, the subset output were digitized using on-screen method. The digitized products were overlain on each other, while a frame marking out the region of interest (ROI) i.e. Ogu-Bolo and Okrika political boundary which lies between latitude 4°48'21.885”N and 4°32'22.202”N and longitude 6°57’50.141"E and 7°15’19.895”E using ArcGIS 10.3. The area covers a land area of approximately 302.47km² (Ogu-Bolo 114.58km² and Okrika 187.8 km²) this boundary was used to mark out the study.
area and subsequently, contour, drainage network, settlements, utilities and other spatial features relevant to achieving the set objectives. Figure 4 shows spilled site due to Artisan refining activities.

3.1 Analytical Methods

The Digital Elevation Model was created from the elevation data obtained from Short Radar Thematic Mapper (SRTM) satellite image and contour extracted from the topographic map. This was achieved by turning on hill shading in the layer properties dialog box by choosing the stretched renderer and checking use hill shade effect (color ramp) to represent various elevation ranges. Triangulated Irregular Network (TIN) were generated from contour (with Z attribute value) and used to generate digital elevation model (DEM). Slope, Flow accumulation, flow direction was produced from the DEM using the Arc GIS 10.3 3-D analyst tool function of Arc GIS Version 10.3. Watershed and other drainage morphometric analysis were generated from drainage map, while land use or land cover and its class statistics were generated from the Land sat image covering. The slope of the study area was derived and modelled by using digital elevation model data, data-set using create slope tool, and the percentage (%) units were included to display the slope.

The spatial resolution of the Digital Elevation Model (DEM) used for this work was 15m, and it was gotten out of SRTM data. The ArcGIS 10.1 3-D surface analysis was used to generate the TIN and slope of the area in percentage while the three 3-D Analyst in ArcScene was used to generate the 3-D visualization of the Groundwater area. From the 3-D visualization the elevation profile graphs
were generated. The elevation profile graphs are cross sectional chart with elevation plotted against distance; this gives terrain explanation of a selected line of sight over a set distance.

## 4. RESULTS AND DISCUSSION

### 4.1 Water Quality Index Model

Water quality index is a 100-point scale that summarizes results from a total of different measurements when complete. It is a dimensionless number that combines multiple water-quality factors into a single number by normalizing values to subjective rating curves (Miller *et al.*, 1986). Factors to be included in WQI model could vary depending upon the designated water uses and local preferences. Some of these factors based on this study includes Polycyclic Aromatic Hydrocarbon (PAH), Total Petroleum Hydrocarbon (TPH), Benzene Toluene Ethyl Benzene Xylene (BTEX), Iron (Fe), Zinc (Zn), Copper (Cu), Lead (Pb), Hydrocarbon Utilizing Bacteria (HUB), Chloride (Cl), Nitrate (Ni), Sulphate (SO\(_4\)), pH, Biological Oxygen Demand (BOD), Chemical Oxygen Demand (COD), Turbidity, Dissolved Oxygen (DO), Temperature etc. These parameters occur in different ranges and expressed in different units. Table 3 shows the descriptive statistics of water quality analysis results in the area. The WQI takes the complex scientific information of these variables and synthesizes into a single number. Graphs are used to convert field data to a Q or Quality Value. The Q value is then multiplied by Weighing Factor to get the Water Quality Index for that parameter. The results are then totalled to get the Overall Water Quality Index. The index equation generates a number from 1 to 100, with 1 being the poorest and 100 indicating the best quality of water. Within this range, designations is set to classify the quality of water as poor, marginal, fair, good or excellent.

**Table 3.** Descriptive statistics of water quality analysis results

| Parameter | Min | Max | Mean | Standard Deviation | Variance | NESREA Limit | WHO (2011) mg/l |
|-----------|-----|-----|------|--------------------|----------|--------------|-----------------|
| Cu        | -   | 0.21| 0.38 | 0.32               | 0.10     | 0.50         | 5.00            |
| Fe        | 0.81| 0.21| 0.14 | 0.06               | 0.00     | 0.05         | 5.00            |
| Zn        | 0.09| 0.13| 0.14 | 0.06               | 0.00     | 0.05         | 0.10            |
| Temp      | 28.70| 30.10| 29.93| 0.76               | 0.57     | 40.00        | 40.00           |
| Cl        | 57.39| 85.36| 70.99| 26.14              | 683.08   | -            | 200 – 300       |
| pH        | 5.70| 6.50| 6.1  | 0.51               | 0.26     | 6.50-8.50    | 6.50-8.50       |
| DO        | 1.90| 2.30| 2.0  | 0.76               | 0.57     | 40.00        | 40.00           |
| Turbidity | 15.70| 18.20| 17.1 | 9.29               | 65.60    | -            | 4.00            |
| COD       | 2.10| 2.30| 2.2  | 0.67               | 0.45     | 30.00        | -               |

**4.2 Water Quality Index (WQI) Interpretation**

The index equation generates a number between 1 and 100 with 1 being the poorest and 100 indicating the best water quality. Within this range, designations have been set to classify water quality as poor, marginal, fair, good and excellent. The designations can be seen in Table 4 while Table 5 shows the water quality rating. Table 6 also shows the general contamination rating of Okrika and Ogu-Bolo. Figure 5 is the general contamination graph rating of Okrika and Ogu/Bolo. Figure 6 shows the Pie Chart of general Contamination in the area as well as the contamination map of the area (Figure 7).
Table 4. Weighting Factors for Different Participating Parameter

| Factor                                    | Weight |
|-------------------------------------------|--------|
| Dissolved Oxygen (DO)                     | 0.1    |
| Faecal coliform                           | 0.1    |
| pH                                        | 0.09   |
| Biological Oxygen Demand (BOD)            | 0.09   |
| Turbidity                                 | 0.08   |
| Total Petroleum Hydrocarbon (TPH)         | 0.07   |
| Temperature                               | 0.07   |
| Polycyclic Aromatic Hydrocarbon (PAH)     | 0.05   |
| Iron (Fe)                                 | 0.05   |
| Chemical Oxygen Demand (COD)              | 0.05   |
| Lead (Pb)                                 | 0.04   |
| Chloride (Cl)                             | 0.04   |
| Benzene Toluene Ethylbenzene Xylene (BTEX)| 0.03   |
| Zinc (Zn)                                 | 0.03   |
| Copper (Cu)                               | 0.03   |
| Hydrocarbon Utilizing Bacteria (HUB)      | 0.03   |
| Nitrate                                   | 0.03   |
| Sulphate (SO₄)                            | 0.02   |

Table 5. Water Quality Rating (Brown et al., 1970 & Ramakrishnaiah et al., 2009)

| Water Quality Index Range | Water Quality Rating |
|---------------------------|----------------------|
| 90-100                    | Excellent            |
| 70-89                     | Good                 |
| 50-69                     | Medium               |
| 25-49                     | Bad                  |
| 0-24                      | Very Bad             |

| Very Bad     | ≤ 28 - 35.8| 0.12  | 12.40| Ibaka, Ibiluya, Ogboogo, Ogoloma, and Okrika.                              |
| Grand Total  | 413.46     | 1.00  | 100.00| Aloacha, Bilemekiri, Davukiri, Greenkeiri, Obuadakiri, and Okungbama.      |
| Std.dev      | 46.65639104|       |     |                                                                           |

5. Conclusion

Results of this study, has shown that water within the study area is not suitable for drinking as well as for other domestic purposes. The study also reveals that there are negative effects of bunkering and artisan refining on the aquifer, and the contaminants are flowing at a very faster rate into the aquifer as a result of the elevation. The physico-chemical analysis on soil and water revealed poor water and soil. Water analysis showed high concentration of Fe and Zn which made the water in such area unsuitable for drinking. Also, the soil samples recorded high levels of crude content from 1m, with concentration reducing with depth up to 3m. Therefore, the following recommendations are made:
(i) Geochemical analysis of water samples should be carried out regularly to determine any future pollution of the water due to the activities in the area.

(ii) Appropriate water treatment of borehole should be done.

(iii) The higher head (highest elevation) should be considered when siting a borehole since the contaminants will have to flow from higher to lower head.

(iv) The activities both anthropogenic and artisan refining should be discouraged.
