APPROXIMATION BY ANALYTIC MATRIX FUNCTIONS.
THE FOUR BLOCK PROBLEM

VLADIMIR. V. PELLER AND SERGEI R. TREIL

Abstract. We study the problem of finding a superoptimal solution to the four block problem. Given a bounded block matrix function
\[
\begin{pmatrix}
\Phi_{11} & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{pmatrix}
\]
on the unit circle the four block problem is to minimize the $L^\infty$ norm of
\[
\begin{pmatrix}
\Phi_{11} - F & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{pmatrix}
\]
over $F \in H^\infty$. Such a minimizing $F$ (an optimal solution) is almost never unique. We consider the problem to find a superoptimal solution which minimizes not only the supremum of the matrix norms but also the suprema of all further singular values. We give a natural condition under which the superoptimal solution is unique.

1. Introduction

The problem of approximating a given scalar function $\varphi$ on the unit circle $\mathbb{T}$ uniformly by functions analytic in the unit disk $\mathbb{D}$ has been attracting analysts for a long time (see [Kha], [RSh], [Ne], [AAK1-2], [CJ], [PKh]). It was shown in [Kha] that for a continuous function $\varphi$ such a best approximation is unique while it is not unique in the general case. Later it turned out that this problem is closely related with Hankel operators. Namely, it was proved by Nehari [Ne] that
\[
\text{dist}_{L^\infty}(\varphi, H^\infty) = \|H_\varphi\|,
\]
where $H_\varphi : H^2 \to H^2 \triangleq L^2 \ominus H^2$ is the Hankel operator with symbol $\varphi$ defined by
\[
H_\varphi f = \mathbb{P}_-\varphi f, \ f \in H^2,
\]
(we denote by $\mathbb{P}_+$ and $\mathbb{P}_-$ the orthogonal projections onto $H^2$ and $H^2_\perp$). Presently the problem of approximating by analytic functions in $L^\infty$ is called Nehari’s problem.

We shall also need the notion of a Toeplitz operator. Given $\varphi \in L^\infty$ the Toeplitz operator $T_\varphi : H^2 \to H^2$ is defined by
\[
T_\varphi f = \mathbb{P}_+\varphi f, \ f \in H^2.
\]

Adamyan, Arov and Krein [AAK1-2] found many interesting connections between Hankel operators and Nehari’s problem. In particular, they found a more general condition under which a best approximation is unique: if the essential norm \( \|H_\varphi\|_e \) is less than \( \|H_\varphi\| \), then \( \varphi \) has a unique best approximation. (Recall that for an operator \( T \) on a Hilbert space

\[
\|T\|_e \overset{\text{def}}{=} \inf \{ \|T - K\| : K \text{ is compact} \}).
\]

This sufficient uniqueness condition can easily be reformulated in terms of the function \( \varphi \) itself since

\[
\|H_\varphi\|_e = \text{dist}_{L^\infty}(\varphi, H^\infty + C)
\]

(see [AAK1-2]). They also found a criterion of uniqueness of a best approximation in terms of the corresponding Hankel operator, and in the case of non-uniqueness parametrized all best approximations (optimal solutions of Nehari’s problem), see [AAK1-2]. However, it is not very easy to verify whether a function \( \varphi \) in \( L^\infty \) satisfies the criterion.

Carleson and Jacobs [CJ] studied smoothness properties of the best approximation for smooth functions \( \varphi \). They proved that if \( \varphi \) belongs to the Hölder–Zygmund class \( \Lambda_\alpha \), \( \alpha > 0 \), \( \alpha \not\in \mathbb{Z} \), then the best approximation also belongs to the same class.

Later in [PKh] more general hereditary properties of the non-linear operator of best approximation were studied. For a large class of function spaces \( X \) on \( \mathbb{T} \) it was proved that if \( \varphi \in X \) and \( f \) is the best approximation by analytic functions, then \( f \in X \). Note also that in [PKh] Nehari’s problem was also applied in prediction theory which led to a new approach to the problem of describing stationary processes satisfying various regularity conditions in terms of their spectral densities.

A new wave of interest in Nehari’s problem was caused by the development of \( H^\infty \) control theory where Nehari’s problem plays a central role (see [Fr]). Moreover, for the needs of \( H^\infty \) control theory it is important to consider Nehari’s problem for matrix-valued functions: given an \( n \times m \) matrix function \( \Phi \) on \( \mathbb{T} \) the problem is to approximate \( \Phi \) by bounded analytic matrix functions \( Q \) in the norm

\[
\|\Phi - Q\|_\infty \overset{\text{def}}{=} \text{ess sup}_{\zeta \in \mathbb{T}} \|\Phi(\zeta) - F(\zeta)\|,
\]

where \( \|\cdot\| \) on the right-hand side is the norm of the matrix as an operator from \( \mathbb{C}^m \) to \( \mathbb{C}^n \). However, in contrast with the scalar case we have uniqueness of a best approximation only in exceptional cases. Indeed, let

\[
\Phi = \begin{pmatrix}
\bar{z} & 0 \\
0 & \frac{1}{2}\bar{z}
\end{pmatrix}.
\]

Clearly \( \text{dist}_{L^\infty}(\bar{z}, H^\infty) = 1 \) and so \( \|\Phi - Q\|_\infty \geq 1 \) for any \( Q \in H^\infty \). However, it is easy to see that any function of the form \( \begin{pmatrix}
0 & 0 \\
0 & q
\end{pmatrix} \) with \( q \in H^\infty \), \( \|q\|_\infty \leq \frac{1}{2} \), is a best
approximation. Intuitively, however, is clear that the “very best” approximation is the zero matrix function $\mathbb{0}$.

In [Y] Young suggested imposing the following additional assumptions on approximating functions. Let $\Omega_0$ be the set of best approximations:

$$\Omega_0 = \{ Q \in H^\infty : Q \text{ minimizes } \text{ess sup}_{\zeta \in T} \| \Phi(\zeta) - Q(\zeta) \| \}.$$ 

Define inductively the sets $\Omega_j$ as follows

$$\Omega_j = \{ Q \in \Omega_{j-1} : Q \text{ minimizes } \text{ess sup}_{\zeta \in T} s_j(\Phi(\zeta) - Q(\zeta)) \}$$

(for a matrix (or an operator) $A$ the $j$th singular value $s_j(A)$, $j \geq 0$, is the distance from $A$ to the set of matrices (operators) of rank at most $j$, $s_0(A) \overset{\text{def}}{=} \| A \|$). Elements of $\Omega_{\min\{m,n\} - 1}$ are called superoptimal approximations of $\Phi$ (or superoptimal solutions of Nehari’s problem). Put

$$t_j \overset{\text{def}}{=} \text{ess sup}_{\zeta \in T} s_j(\Phi(\zeta) - Q(\zeta)), \quad Q \in \Omega_j.$$ 

The numbers $t_j$, $0 \leq j \leq \min\{m,n\} - 1$, are called the superoptimal singular values. As in the scalar case, $t_0 = \| H\Phi \|$ (the Hankel operator $H\Phi : H^2(\mathbb{C}^n) \to H^2(\mathbb{C}^m)$ is defined in the same way as in the scalar case).

Note that $Q$ is a superoptimal solution of Nehari’s problem if and only if it lexicographically minimizes the sequence $\{s_j(\Phi - Q)\}_{j \geq 0}$, where for a matrix function $F$ on $T$

$$s_j^\infty(F) \overset{\text{def}}{=} \text{ess sup}_{\zeta \in T} s_j(F(\zeta)).$$

It was proved in [PY1] that for $\Phi \in H^\infty + C$ there exists a unique superoptimal approximation $Q$. The method of the proof in [PY1] is based on certain special factorizations of matrix functions (thematic factorizations) and it is constructive. Later in [T] another method was suggested to establish uniqueness in the $H^\infty + C$ case which is based on weighted Nehari’s problem.

However in the case when the Hankel operator $H\Phi$ is non-compact, there was no analog of the Adamyan–Arov–Krein sufficient condition for uniqueness in the case of matrix functions.

Nehari’s problem is a special case of the so-called four block problem which is one of the most important problems in control theory. Let $\Phi$ be a block matrix function of the form

$$\Phi = \begin{pmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix}.$$
Here Φ has size $m \times n$, $\Phi_{11}$ has size $m_1 \times n_1$, and $\Phi_{2}$ has size $m_2 \times n_2$. The four block problem is to minimize

$$\left\| \begin{pmatrix} \Phi_{11} - Q & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} \right\|_\infty,$$

(1.1)

over bounded analytic functions $Q$ of size $m_1 \times n_1$. A function $Q \in H^\infty(M_{m_1,n_1})$ is called an optimal solution of the four block problem if it minimizes the norm (1.1).

The four block problem arises naturally when one considers the following (model-matching) problem in $H^\infty$ control. Let $F$, $G_1$ and $G_2$ be matrix functions of class $H^\infty$. The problem is to minimize

$$\| F - G_1 Q G_2 \|_\infty$$

(1.2)

over $Q \in H^\infty$ (the sizes of the matrix functions in (1.2) are such that (1.2) is meaningful). Many problems in $H^\infty$ control reduce to the model-matching problem.

Engineers usually consider the case of continuous (on $\mathbb{T}$), or even rational functions $G_1$ and $G_2$ and assume that these functions have constant rank on the boundary. Under this assumption the model-matching problem reduces to the four block problem (1.1), while it reduces to Nehari’s problem only if the matrices $G_2$, $G^*_1$ have maximal column rank (the rank equals the number of columns). The assumption on the maximal column rank does not hold for many interesting applied problems, so engineers have to consider the four block problem as well.

In the most general case the model matching problem (1.2) reduces to the four block problem under the assumption that the outer parts of functions $G_1$ and $G_2$ are right invertible in $L^\infty$ (for continuous functions this is equivalent to fact that they have constant rank on $\mathbb{T}$). The model matching problem reduces to Nehari’s problem if the outer parts of functions $G_1$ and $G_2^*$ are invertible in $L^\infty$ (which for continuous functions is equivalent to the above maximal column rank assumption).

By analogy with Hankel operators we define the four block operator $\Gamma_\Phi : H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2}) \to H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$ by

$$\Gamma_\Phi \left( \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} \right) = \mathbb{P}^- \Phi \left( \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} \right),$$

where $\mathbb{P}^-$ is the orthogonal projection from $L^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$ onto $H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$. As in the case of Hankel operators the infimum in (1.1) is equal to $\| \Gamma_\Phi \|$ (see [FT]). The matrix function $\Phi$ is called a symbol of the four block operator $\Gamma_\Phi$ (a four block operator has many different symbols).

As in the case of Nehari’s problem we can define the sets $\Omega_j$:

$$\Omega_0 = \left\{ Q \in H^\infty : Q \text{ minimizes } \left\| \begin{pmatrix} \Phi_{11} - F & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} \right\|_\infty \right\},$$
\[ \Omega_j = \left\{ Q \in \Omega_{j-1} : Q \text{ minimizes} \sup_{\zeta \in T} s_j \left( \begin{pmatrix} \Phi_{11} - F & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} (\zeta) \right) \right\}. \]

Q is called a superoptimal solution of the four block problem (1.1) if \( Q \in \Omega_{\min\{m_1,n_1\}-1} \).

We define the superoptimal singular values of the four block problem (1.1) by

\[ t_j = \sup_{\zeta \in T} s_j \left( \begin{pmatrix} \Phi_{11} - Q & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} (\zeta) \right), \quad F \in \Omega_j. \]

Clearly, \( t_0 = \|\Gamma \Phi\| \).

We say that a \( \Phi \) is a superoptimal symbol of a four block operator \( \Gamma \) if \( \Gamma = \Gamma_\Phi \) and the zero function is a superoptimal solution of the corresponding four block problem.

Using a simple compactness argument one can prove easily that a superoptimal solution always exists. However we cannot expect a sufficient condition for uniqueness of the superoptimal approximation which would be similar to the one found in [PY1] in the case of Nehari’s problem. Indeed it can easily be proved that a four block operator cannot be compact unless \( \Phi_{12}, \Phi_{21}, \) and \( \Phi_{22} \) are identically equal to zero in which case the four block problem is equivalent to Nehari’s problem.

The main result of the paper (Theorem 2.1) is a sufficient condition for the four block problem to have a unique superoptimal solution. This result can be considered as an analog of the Adamyan–Arov–Krein theorem mentioned above which deals with Nehari’s problem in the scalar case. Note that Theorem 2.1 also gives us a new result for Nehari’s problem in the case when the corresponding Hankel operator is non-compact.

The proof is constructive. We give an algorithm to find the unique superoptimal solution. The algorithm is similar to the one given in [PY1], it reduces the problem to the case of matrix functions of lower size. However the proof is considerably more complicated than in the case of Nehari’s problem with compact Hankel operator.

In Section 3 we describe briefly the method of factorization and diagonalization. We construct important matrix functions \( V \) and \( W \) which can be considered as analogs of the thematic functions defined in [PY1].

In Section 4 we use the construction of Section 3 to parametrize all optimal solutions of the four block problem. This allows us to reduce the problem of finding superoptimal solutions to the case of matrix functions of lower size.

Section 5 is devoted to the proof of the fact that the matrix functions \( V_c \) and \( W_c \) which are submatrices of \( V \) and \( W \) are left invertible in \( H^\infty \). This is one of the principal points in the proof of the main result.

In Section 6 we prove another crucial fact for the proof of the main result. Namely, we show that if \( \Phi \) satisfies the hypotheses of Theorem 2.1, then the lower order four block problem, obtained as a result of parametrization in Section 4, also satisfies the hypotheses of Theorem 2.1. This makes it possible to continue the process and complete the proof of the main result.
In Section 7 we study superoptimal symbols of four block operators. We obtain certain special factorizations of such symbols (thematic factorizations), and define the indices of such factorizations. In the case of Nehari’s problem with compact Hankel operators such factorizations were found in [PY1].

To prove the invariance of indices we introduce in Section 8 the notion of a superoptimal weight for the four block operator. This is an analog of the notion introduced in [T] in the case of compact Hankel operators.

In Section [9] we use superoptimal weights to prove that the sums of the indices in a thematic factorization which correspond to equal superoptimal singular values do not depend on the choice of factorization. In the case of compact Hankel operators this invariance property was proved in [PY2]. Note that as in the case of Nehari’s problem for $H^\infty + C$ functions if there are equal superoptimal singular values, the indices can depend on the choice of thematic factorization (see [PY2]).

The last section is devoted to inequalities between the superoptimal singular values and the singular values of the four block operator. We obtain an inequality which is new even in the case of Nehari’s problem with compact Hankel operator. It is stronger than the one obtained in [PY2].

Note that in [PY1] hereditary properties of the non-linear operator of superoptimal approximation were studied. It was shown there that for a large class of function spaces $X$ the inclusion $\Phi \in X$ implies that the superoptimal approximant to $\Phi$ also belongs to $X$. It would be interesting to find analogs of such results in the case of the four block problem. In particular we do not know whether the superoptimal solution of the four block problem ([.1]) must belong to a Hölder class $\Lambda$ if $\Phi \in \Lambda$.

Throughout this paper we shall denote by $M_{m,n}$ the space of $m \times n$ matrices. We shall use the notation $L^\infty(M_{m,n})$ and $H^\infty(M_{m,n})$ for the spaces of bounded and bounded analytic functions which take values in $M_{m,n}$. Sometimes if it does not lead to a confusion, we shall simply write $L^\infty$ and $H^\infty$ instead of $L^\infty(M_{m,n})$ and $H^\infty(M_{m,n})$.

A matrix function $\Theta \in H^\infty$ is called inner if $\Theta(\zeta)$ is isometric for almost all $\zeta \in \mathbb{T}$. A matrix function $F \in H^\infty(M_{m,n})$ is called outer if $FH^2(\mathbb{C}^n)$ is dense in $H^2(\mathbb{C}^m)$. A function $F \in H^\infty(M_{m,n})$ is called co-outer if the transposed function $F^t \in H^\infty(M_{n,m})$ is outer.

2. The main result
In this section we state the main result of the paper as well as important corollaries. Let \( \Phi \) be a matrix function of the form
\[
\Phi = \begin{pmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix},
\]
where \( \Phi \) has size \( m \times n \), \( \Phi_{11} \) has size \( m_1 \times n_1 \), and \( \Phi_{22} \) has size \( m_2 \times n_2 \). Recall that \( \Gamma_\Phi \) is the four block operator defined in Section 1 and \( \{t_j\} \) is the sequence of superoptimal singular values.

The following theorem is the main result of the paper.

**Theorem 2.1.** Let \( \Phi \) be a bounded function of the form (2.1). Suppose that \( \|\Gamma_\Phi\|_e \) is less than the smallest nonzero superoptimal singular value. Then there exists a unique superoptimal solution \( Q \) of the four block problem for \( \Phi \). The singular values
\[
s_j \left( \begin{pmatrix} \Phi_{11} - Q & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} (\zeta) \right), \quad 1 \leq j \leq d - 1,
\]
are constant on \( \mathbb{T} \).

The following partial case of Theorem 2.1 improves the result of [PY1] on uniqueness of superoptimal solutions of Nehari’s problem.

**Theorem 2.2.** Let \( \Phi \) be bounded matrix function on \( \mathbb{T} \). Suppose that \( \|H_\Phi\|_e \) is less than the smallest nonzero superoptimal singular value of Nehari’s problem. Then \( \Phi \) has a unique superoptimal approximation \( Q \) by bounded analytic matrix functions. The singular values \( s_j(\Phi(\zeta) - Q(\zeta)) \) are constant on \( \mathbb{T} \).

3. Diagonalization

In this section we start with a maximizing vector of the four block operator and we construct a certain special unitary-valued matrix. This allows us to achieve a diagonalization. Later using this diagonalization we shall reduce the problem to the case of a matrix function of a lower size.

**Lemma 3.1.** Let \( v \) be an \( n \times 1 \) inner matrix function. Then there exists a co-outer function \( V_c \in H^\infty(M_{n,n-1}) \) such that the matrix function
\[
V \overset{\text{def}}{=} \begin{pmatrix} v & V_c \end{pmatrix}
\]
is unitary-valued on \( \mathbb{T} \).
In [PY1] a stronger result was obtained. It was shown that all minors of $V$ on the first column are in $H^\infty$. This property of analyticity of minors was essential for the proof of the uniquesness of a superoptimal solution of Nehari’s problem which was given in [PY1]. Earlier the existence of a co-outer $V_c$ satisfying the requirement of Lemma 3.1 was proved in [Va], however the property of analyticity of minors was not noticed in [Va]. It also can be shown that if we $V^{(1)}$ and $V^{(2)}_c$ are $n \times (n-1)$ co-outer functions satisfying the requirements of Lemma 3.1, then there exists a constant unitary matrix $U$ such that $V^{(1)}_c = V^{(2)}_c U$ (see [Va], [PY1]).

To start the procedure we need a maximizing vector of the four block operator $\Gamma_\Phi$, i.e., a nonzero vector $f \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2})$ such that $\|\Gamma_{\Phi} f\| = \|\Gamma_{\Phi}\| \cdot \|f\|$. If $\Phi$ satisfies the hypotheses of Theorem 2.1 and $\Gamma_{\Phi} \neq 0$, then $\|\Gamma_{\Phi}\| = t_0 > \|\Gamma_{\Phi}\|_e$ and so a maximizing vector for $\Gamma_{\Phi}$ exists.

The following fact is well-known in the case of Hankel operators (see [AAK3]). The proof of it in the case of four block operators is similar.

**Lemma 3.2.** Let $\Phi$ be a matrix function on $T$ of the form (2.1) and such that $\|\Phi\|_\infty = \|\Gamma_{\Phi}\|$. Suppose that $f$ is a maximizing vector for $\Gamma_{\Phi}$ and put $g = t_0^{-1} \Gamma_{\Phi} f$. Then $\Gamma_{\Phi} f = \Phi f$ and $\|g(\zeta)\|_{C^m} = \|f(\zeta)\|_{C^n}$ a.e. on $T$. Furthermore $\|\Phi(\zeta)\| = \|\Phi\|_\infty$ a.e. on $T$.

**Proof.** We have

$$\|\Gamma_{\Phi} f\|_2 = \|P^- \Phi f\|_2 \leq \|\Phi f\|_2 \leq \|\Phi\|_\infty \|f\|_2 = \|\Gamma_{\Phi}\| \cdot \|f\|_2 = \|\Gamma_{\Phi} f\|_2.$$  

It follows that all inequalities in this chain are, in fact, equalities. The fact that $\|P^- \Phi\|_2 = \|\Phi\|_2$ certainly means that $\Phi f \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2})$ and so $\Gamma_{\Phi} f = \Phi f$. The equality $\|\Phi f\|_2 = \|\Phi\|_\infty \|f\|_2$ implies that $\|g(\zeta)\|_{C^m} = \|f(\zeta)\|_{C^n}$ a.e. on $T$, which in turn implies that $\|\Phi(\zeta)\| = \|\Phi\|_\infty$ for almost all $\zeta \in T$. ■

**Lemma 3.3.** Let $\Phi$ be a matrix function of the form (2.1) such that $\|\Gamma_{\Phi}\|_e < \|\Gamma_{\Phi}\|$. Suppose that $f = f_1 \oplus f_2$ is a maximizing vector for $\Gamma_{\Phi}$ and $t_0 g = g_1 \oplus g_2 = \Gamma_{\Phi} f$, where $f_1 \in H^2(\mathbb{C}^{n_1})$, $f_2 \in L^2(\mathbb{C}^{n_2})$, $g_1 \in H^2(\mathbb{C}^{m_1})$, and $g_2 \in L^2(\mathbb{C}^{m_2})$. Then

$$\|f_1(\zeta)\|_{C^{m_1}}^2 \geq \frac{\|\Gamma_{\Phi}\|^2 - \|\Gamma_{\Phi}\|_e^2}{\|\Gamma_{\Phi}\|^2} \|f(\zeta)\|_{C^n}^2, \quad \|g_1(\zeta)\|_{C^{m_1}}^2 \geq \frac{\|\Gamma_{\Phi}\|^2 - \|\Gamma_{\Phi}\|_e^2}{\|\Gamma_{\Phi}\|^2} \|g(\zeta)\|_{C^n}^2$$

almost everywhere on $T$.

**Proof.** By subtracting an optimal solution, we can assume that $\|\Phi\|_\infty = \|\Gamma_{\Phi}\|$. By Lemma 3.2, $t_0 g(\zeta) = \Phi(\zeta) f(\zeta)$ and $\|g(\zeta)\|_{C^n} = \|f(\zeta)\|_{C^n}$ a.e. on $T$. Therefore $f(\zeta)$ is a maximizing vector for $\Phi(\zeta)$ and $g(\zeta)$ is a maximizing vector for $\Phi^*(\zeta)$. We have
\[ g_2 = \left( \begin{array}{c} \Phi_{21} \\ \Phi_{22} \end{array} \right) f. \] It is well known that
\[ \left\| \Gamma \left( \begin{array}{c} 0 \\ \Phi_{21} & \Phi_{22} \end{array} \right) \right\|_e = \left\| \Gamma \left( \begin{array}{c} 0 \\ \Phi_{21} & \Phi_{22} \end{array} \right) \right\| = \left\| \left( \begin{array}{c} \Phi_{21} \\ \Phi_{22} \end{array} \right) \right\|_{\infty} \]
and so
\[ \left\| \left( \begin{array}{c} \Phi_{21} \\ \Phi_{22} \end{array} \right) \right\|_{\infty} \leq \| \Gamma \|_e. \]
Hence
\[ \| \Gamma \| \cdot \| g_2(\zeta) \|_{C_{m_2}} \leq \left\| \left( \begin{array}{c} \Phi_{21} \\ \Phi_{22} \end{array} \right) \right\|_\infty \| f(\zeta) \|_{C_n} \leq \| \Gamma \|_e \| f(\zeta) \|_{C_n}. \]

On the other hand
\[ \| g(\zeta) \|_{C_m}^2 = \| g_1(\zeta) \|_{C_{m_1}}^2 + \| g_2(\zeta) \|_{C_{m_2}}^2 = \| f(\zeta) \|_{C_n}^2. \]

Therefore
\[ \| g_1 \|_{C_{m_1}}^2 \geq \frac{\| \Gamma \|_{\infty}^2 - \| \Gamma \|_e^2 \| f(\zeta) \|_{C_n}^2}{\| \Gamma \|_{\infty}^2}. \]

To prove the inequality for \( f_1(\zeta) \) we can use the same argument since \( t_0 f(\zeta) = \Phi^*(\zeta) g(\zeta) \) and
\[ \left\| \left( \begin{array}{c} \Phi^*_{11} \\ \Phi^*_{22} \end{array} \right) \right\| = \left\| \left( \begin{array}{c} \Phi_{12} \\ \Phi_{22} \end{array} \right) \right\| = \left\| \Gamma \left( \begin{array}{c} 0 \\ \Phi_{12} & \Phi_{22} \end{array} \right) \right\|_e = \left\| \Gamma \left( \begin{array}{c} 0 \\ \Phi_{12} & \Phi_{22} \end{array} \right) \right\|. \]

**Corollary 3.4.** Let \( \Phi \) be a matrix function of the form (2.1) such that \( \| \Gamma \|_e < \| \Gamma \|. \) Suppose that \( \min\{m_1, n_1\} = 1. \) Then there exists a unique optimal solution of the four block problem.

**Proof.** It is sufficient to consider the case \( n_1 = 1. \) To obtain the result in the case \( m_1 = 1 \) we can pass to the transpose of \( \Gamma. \) Let \( f = f_1 \oplus f_2 \) be a maximizing vector of \( \Gamma \) and let \( Q \in H^\infty(M_{m_1}) \) be an optimal solution of the four block problem, i.e.,
\[ \left\| \left( \begin{array}{c} \Phi_{11} - Q \\ \Phi_{21} \end{array} \right) \right\| = \| \Gamma \|. \]

It follows from Lemma 3.3 that \( f_1 \) is a nonzero scalar function in \( H^2. \) By Lemma 3.2
\[ \left( \begin{array}{c} \Phi_{11} - Q \\ \Phi_{21} \end{array} \right) \left( \begin{array}{c} f_1 \\ f_2 \end{array} \right) = \Gamma f. \]

Therefore \( Qf_1 \) is uniquely determined by \( \Gamma \) and \( f \) (\( Q \) is a column matrix) and since \( f_1 \neq 0, \) it follows that \( Q \) is uniquely determined by \( \Phi. \)

Now, following ideas of [PY1] we construct diagonalizing matrix functions \( V \) and \( W \) in the following way.
Take a maximizing vector \( f = f_1 \oplus f_2, f_1 \in H^2(\mathbb{C}^{n_1}), f_2 \in L^2(\mathbb{C}^{n_2}) \). Let \( h \) be a scalar outer function such that \( |h(\zeta)|^2 = \|f(\zeta)\|_{C^2}, \zeta \in \mathbb{T} \). Such a function \( h \) always exists since \( f_1 \in H^2 \) and \( f_1 \neq 0 \). Denote by \( \hat{\vartheta} \) a greatest common inner divisor of the entries of \( f_1 \) (it may happen that \( \hat{\vartheta} = 1 \)). Define the vector \( v = v_1 \oplus v_2 \in H^\infty(\mathbb{C}^{n_1}) \oplus L^\infty(\mathbb{C}^{n_2}) \) by \( v = \hat{\vartheta} f/h \). Clearly, \( \|v(z)\| = 1 \) a.e. on \( \mathbb{T} \). The vector \( v \) will be the first column of the matrix \( V \).

We can represent the column function \( v_1 \) as \( v_1 = v(o) v(i) \) where \( v(o) \) is a scalar outer function such that \( |v(o)(\zeta)| = \|v_1(\zeta)\|_{C^{n_1}} \) a.e. on \( \mathbb{T} \) and \( v(i) \) is an inner column function (the inner part of \( v_1 \)), i.e., \( \|v(i)(\zeta)\|_{C^{n_1}} = 1 \) a.e. on \( \mathbb{T} \). Applying Lemma \([3.1]\) to \( v = v(i) \), we obtain an inner and co-outer matrix \( V_c \) such that the matrix \( \begin{cases} v_1 & V_c \\ v_2 & \emptyset \end{cases} \) is unitary-valued. Note that the vector-function \( v(i) \) is pointwise orthogonal to any column of \( V_c \) a.e. on \( \mathbb{T} \), and so the same is true for \( v_1 \). So the matrix function

\[
\begin{pmatrix} v_1 & V_c \\ v_2 & \emptyset \end{pmatrix}
\]

(3.1)

is isometric almost everywhere on \( \mathbb{T} \).

It is easy to see that we can complete this matrix function by adding \( m_2 \) measurable column functions to obtain a unitary-valued function. Indeed it is sufficient to complete the matrix function to a square matrix function whose columns are pointwise linear independent and then apply the Gram-Schmidt orthogonalization process to the columns. To this end we can approximate our matrix function uniformly by step functions which take isometric values. Clearly, we can find a unitary completion for each step function. It is easy to see that if the distance from a step function to our initial function is sufficiently small, then the columns of our initial function and the columns we added to the step function are linearly independent.

Let \( V \) be a unitary-valued completion of the matrix (3.1). Then \( V \) has the form

\[
V = \begin{pmatrix} v_1 & V_c \\ v_2 & \emptyset \end{pmatrix}
\]

Let us now construct a unitary-valued matrix \( W \) in a similar way. Let \( t_0 g = \Gamma \Phi f \).

Then by Lemma \([3.2]\) \( \|g(\zeta)\| = \|f(\zeta)\| = |h(\zeta)|, \zeta \in \mathbb{T} \). Let \( \tau \) be a greatest common inner divisor of all entries of \( \tilde{e}_7 \) (recall that \( g = g_1 \oplus g_2, g_1 \in H^2(\mathbb{C}^{m_1}), g_2 \in L^2(\mathbb{C}^{m_2}) \)). Define the column function \( w = w_1 \oplus w_2 \in H^\infty(\mathbb{C}^{m_1}) \oplus L^\infty(\mathbb{C}^{m_2}) \) by \( w = \tilde{e}_7 \tilde{g}/h \).

By analogy with (3.1) we can find a co-outer matrix function \( W_c \) such that the matrix function \( \begin{pmatrix} w_1 & W_c \\ w_2 & \emptyset \end{pmatrix} \) takes isometric values on \( \mathbb{T} \). We can complete this matrix function to a unitary-valued matrix function and define \( W \) to be its transpose:

\[
W^t = \begin{pmatrix} w_1 & W_c \\ w_2 & \emptyset \end{pmatrix}
\]
To prove Theorem 2.1 we shall proceed as follows. Let $Q_0$ be an optimal solution of the four block problem. We shall prove in the next section that the matrix function 

$$\begin{pmatrix} \Phi_{11} - Q_0 & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix}$$

admits a representation

$$\begin{pmatrix} \Phi_{11} - Q_0 & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} = W^* \begin{pmatrix} t_0 u_0 & \odot & \odot & \odot \\ \odot & \Phi_{11}^{(1)} & \Phi_{12}^{(1)} \\ \odot & \Phi_{21}^{(1)} & \Phi_{22}^{(1)} \end{pmatrix} V^*,$$

where $u_0 = \bar{z} \bar{\tilde{p}} \bar{h}/h$ and $\Phi_{11}^{(1)}$ is a matrix function of size $(m_1 - 1) \times (n_1 - 1)$. We shall also prove in Section 4 that if $Q$ is another optimal solution, then

$$\begin{pmatrix} \Phi_{11} - Q & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{pmatrix} = W^* \begin{pmatrix} t_0 u_0 & \odot & \odot & \odot \\ \odot & \Phi_{11}^{(1)} - Q_1 & \Phi_{12}^{(1)} \\ \odot & \Phi_{21}^{(1)} & \Phi_{22}^{(1)} \end{pmatrix} V^*,$$

where $Q_1 \in H^\infty(M_{m_1-1,n_1-1})$ and

$$\left\| \begin{pmatrix} \Phi_{11}^{(1)} - Q_1 & \Phi_{12}^{(1)} \\ \Phi_{21}^{(1)} & \Phi_{22}^{(1)} \end{pmatrix} \right\|_\infty \leq t_0.$$

Since $V$ and $W$ are unitary-valued, it is easy to see that $Q$ is a superoptimal solution to the four block problem for the matrix function $\Phi$ if and only if $Q_1$ is a superoptimal solution to the four block problem for the matrix function

$$\Phi^{(1)} = \begin{pmatrix} \Phi_{11}^{(1)} & \Phi_{12}^{(1)} \\ \Phi_{21}^{(1)} & \Phi_{22}^{(1)} \end{pmatrix}.$$

Moreover, if $t_0, t_1, \ldots, t_{d-1}$ is sequence of superoptimal singular values of the four block problem for $\Phi$, then $t_1, \ldots, t_{d-1}$ is the sequence of superoptimal singular values of the four block problem for $\Phi^{(1)}$. This reduction allows us to diminish the size of the matrix function $\Phi_{11}$.

If $\Gamma_{\Phi^{(1)}} = \emptyset$, we clearly have uniqueness. To continue this process we have to be able to find a maximizing vector for the four block operator $\Gamma_{\Phi^{(1)}}$. We can certainly do that if its essential norm is still less than the smallest nonzero superoptimal singular value. In Section 6 we shall prove that $\|\Gamma_{\Phi^{(1)}}\|_e \leq \|\Gamma_{\Phi}\|_e$ which will allow us to continue the process and reduce Theorem 2.1 to Corollary 3.4.

4. Parametrization of optimal solutions
In this section we describe the optimal solutions of the four block problem in case when \( \| \Gamma \Phi \|_e < \| \Gamma \Phi \| \).

**Lemma 4.1.** Let \( \Phi \) be a block matrix function of the form (2.1) such that \( \| \Gamma \Phi \|_e < \| \Gamma \Phi \| \), and let \( V \) and \( W \) be the matrix functions constructed in Section 3. Then there exists a unimodular function \( u_0 \) such that any optimal solution \( Q_0 \) of the four block problem satisfies

\[
\left( \begin{array}{cc}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{array} \right) = W^* \left( \begin{array}{ccc}
t_0u_0 & 0 & 0 \\
0 & \Phi_{11}^{(1)} & \Phi_{12}^{(1)} \\
0 & \Phi_{21}^{(1)} & \Phi_{22}^{(1)}
\end{array} \right) V^*,
\]

where \( \Phi_{11}^{(1)} \) is a matrix function of size \( m_1 - 1 \times n_1 - 1 \). The unimodular function \( u_0 \) admits a representation \( u_0 = \bar{z} \bar{b} \bar{h}/h \), where \( h \) is an outer function in \( H^2 \) and \( b \) is a finite Blaschke product. Moreover, the Toeplitz operator \( T_{u_0} \) is Fredholm and \( \text{Range } T_{u_0} = H^2 \).

**Proof.** Let \( f = f_1 \oplus f_2 \) be a maximizing vector for \( \Gamma \Phi \) and let \( \Gamma \Phi f = t_0g = t_0(g_1 \oplus g_2) \). Put \( u_0 = \bar{z} \bar{\tau} \bar{h}/h \) (see the construction of the matrix functions \( V \) and \( W \) in Section 3).

By Lemma 3.2, \( f(\zeta) \) is a maximizing vector for \( \left( \begin{array}{cc}
\Phi_{11}(\zeta) - Q_0(\zeta) & \Phi_{12}(\zeta) \\
\Phi_{21}(\zeta) & \Phi_{22}(\zeta)
\end{array} \right) \) almost everywhere on \( T \) and

\[
\left( \begin{array}{cc}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{array} \right) f = t_0g.
\]

Therefore \( g(\zeta) \) is a maximizing vector for \( \left( \begin{array}{cc}
\Phi_{11}(\zeta) - Q_0(\zeta) & \Phi_{12}(\zeta) \\
\Phi_{21}(\zeta) & \Phi_{22}(\zeta)
\end{array} \right)^* \) for almost all \( \zeta \in T \) and so

\[
\left( \begin{array}{cc}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{array} \right)^* g = t_0f. \tag{4.2}
\]

Since \( f = \partial h \left( \begin{array}{c}
v_1 \\
v_2
\end{array} \right) \) and \( \bar{z} \bar{g} = \tau h \left( \begin{array}{c}
w_1 \\
w_2
\end{array} \right) \), we have

\[
\partial h \left( \begin{array}{cc}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{array} \right) \left( \begin{array}{c}
v_1 \\
v_2
\end{array} \right) = t_0 \bar{z} \bar{\tau} \bar{h} \left( \begin{array}{c}
w_1 \\
w_2
\end{array} \right).
\]

It follows from the definition of the matrix functions \( V \) and \( W \) (see Section 3) that

\[
\partial h \left( \begin{array}{cc}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{array} \right) V \left( \begin{array}{c}
1 \\
\vdots \\
0
\end{array} \right) = t_0 \bar{z} \bar{\tau} \bar{h} W^* \left( \begin{array}{c}
1 \\
\vdots \\
0
\end{array} \right).
\]
It is easy to see that the first column of \( W \left( \begin{array}{cc} \Phi_{11} - Q_0 & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{array} \right) V \) has the form 
\( \begin{bmatrix} t_0 u_0 & \cdots & \cdots & 0 \end{bmatrix} \), where 
\( u_0 \triangleq z \bar{\vartheta} \bar{\tau} h/h \). Similarly, using (4.2) we find that the first row of 
\( W \left( \begin{array}{cc} \Phi_{11} - Q_0 & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{array} \right) V \) has the form 
\( \begin{bmatrix} t_0 u_0 & \cdots & \cdots & 0 \end{bmatrix} \), which proves that 
\( \left( \begin{array}{cc} \Phi_{11} - Q_0 & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{array} \right) \) has the form \( \left( \begin{array}{cc} 1 & 0 \\ \Phi_{21} & \Phi_{22} \end{array} \right) \).

Let us show that the Toeplitz operator \( T_{u_0} \) is Fredholm and is onto. Clearly, \( \|H_{u_0}\| = 1 \), since \( \|H_{u_0} h\| = \|P_- z \bar{\vartheta} \bar{\tau} h\| = \|z \bar{\vartheta} \bar{\tau} h\| = \|h\| \). We claim that \( \|H_{u_0}\|_e < 1 \). Indeed, let \( f \) be a scalar function in \( H^2 \). We have

\[
\begin{align*}
\Gamma_{\Phi} v f &= P_- \left( \begin{array}{cc} \Phi_{11} - Q_0 & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{array} \right) \left( \begin{array}{c} v_1 f \\ v_2 f \end{array} \right) \\
&= P_- W^* \left( \begin{array}{cccc} t_0 u_0 & 0 & \cdots & 0 \\
0 & \Phi_{11}^{(1)} & \cdots & 0 \\
0 & \Phi_{21}^{(1)} & \cdots & 0 \\
0 & \Phi_{22}^{(1)} & \cdots & 0 \end{array} \right) \left( \begin{array}{c} v_1 f \\ v_2 f \end{array} \right) \\
&= P_- W^* \left( \begin{array}{cccc} t_0 u_0 & 0 & \cdots & 0 \\
0 & \Phi_{11}^{(1)} & \cdots & 0 \\
0 & \Phi_{21}^{(1)} & \cdots & 0 \\
0 & \Phi_{22}^{(1)} & \cdots & 0 \end{array} \right) \left( \begin{array}{c} f \\ 0 \\ \vdots \\ 0 \end{array} \right) = t_0 P_- \left( \frac{w_1 u_0 f}{w_2 u_0 f} \right)
\end{align*}
\]

Therefore
\[
\begin{align*}
P_- w^t \Gamma_{\Phi} v f &= t_0 P_- w^t P_- \left( \frac{w_1 u_0 f}{w_2 u_0 f} \right) = t_0 P_- \left( \begin{array}{cc} w_1 & 0 \\ w_2 & 0 \end{array} \right) \left( \frac{w_1 u_0 f}{w_2 u_0 f} \right) = t_0 H_{u_0} f,
\end{align*}
\]

whence
\[
t_0 \|H_{u_0}\|_e \leq \|v\|_2 \|w\|_2 \|\Gamma_{\Phi}\|_e = \|\Gamma_{\Phi}\|_e < t_0,
\]

which implies that \( \|H_{u_0}\|_e < 1 \).

Since \( \|H_{u_0}\|_e = \text{dist}_{L^\infty}(u_0, H^\infty + C) \) (see e.g., [S], [Ni]), it follows that \( \|H_{u_0}\|_e = \lim_{j \to \infty} \text{dist}_{L^\infty}(z^j u_0, H^\infty) \). We have \( \|H_{u_0} h\| = \|h\| \). So dist\((u_0, H^\infty) = \|H_{u_0}\| = 1 \). Therefore there exists a \( j \in \mathbb{Z}_+ \) such that
\[
\text{dist}_{L^\infty}(z^j u_0, H^\infty) = 1 \quad \text{and} \quad \text{dist}_{L^\infty}(z^{j+1} u_0, H^\infty) < 1.
\]

This means that \( T_{z^{j+1} u_0} \) is left invertible and \( T_{z^j u_0} \) is not left invertible which implies that \( T_{z^{j+1} u_0} \) is invertible (see [Ni]). Clearly, \( T_{z^{j+1} u_0} = T_{u_0} T_{z^j u_0} \), \( T_{z^{j+1}} \) is Fredholm and so is \( T_{u_0} \).

Since \( u_0 \) has the form \( u_0 = z \bar{\vartheta} \bar{\tau} h/h \), where \( \vartheta \) and \( \tau \) are inner and \( h \) is an outer function in \( H^2 \), the Toeplitz operator has dense range (see [PKh]) which together with the Fredholmness of \( T_{u_0} \) implies that \( T_{u_0} \) is onto.
It remains to show that both $\vartheta$ and $\tau$ are finite Blaschke products. Indeed, if $\kappa$ is an inner divisor of $\vartheta \tau$, it is easy to see that $\kappa h \in \text{Ker} T_{u_0}$ and since $T_{u_0}$ is Fredholm, $\text{Ker} T_{u_0}$ is finite dimensional, which implies that both $\vartheta$ and $\tau$ are finite Blaschke products. ■

**Theorem 4.2.** Let $\Phi$ be a block matrix function of the form (2.1) such that $\|\Gamma_\Phi\|_e < \|\Gamma_\varphi\|$ and let $Q_0$ be an optimal solution of the four block problem. Suppose that $V, W, u_0, \Phi^{(1)}_{11}, \Phi^{(1)}_{12}, \Phi^{(1)}_{21}, \Phi^{(1)}_{22}$ satisfy (4.1) holds. Let $Q$ be a matrix function of size $m_1 \times n_1$. Then $Q$ is an optimal solution of the four block problem if and only if there exists $Q_1 \in H^\infty(M_{m_1-1,n_1-1})$ that satisfies the following conditions:

$$
\begin{pmatrix}
\Phi_{11} - Q_{11} & \cdots & \Phi_{12} \\
\vdots & \ddots & \vdots \\
\Phi_{21} & \cdots & \Phi_{22}
\end{pmatrix} = W^* \begin{pmatrix}
\begin{pmatrix}
\Phi_{11}^{(1)} & 0 & 0 \\
0 & \Phi_{12}^{(1)} & 0 \\
0 & 0 & \Phi_{22}^{(1)}
\end{pmatrix} - Q_{11} & \cdots & \Phi_{12}^{(1)} - Q_{12} \\
0 & \cdots & 0 \\
0 & 0 & 0
\end{pmatrix} V^*,
$$

(4.3)

$$
\left\| \begin{pmatrix}
\Phi_{11}^{(1)} - Q_{11} & \cdots & \Phi_{12}^{(1)} \\
\vdots & \ddots & \vdots \\
\Phi_{21}^{(1)} & \cdots & \Phi_{22}^{(1)}
\end{pmatrix} \right\|_\infty \leq t_0.
$$

(4.4)

To prove Theorem 4.2 we need the following result from [PY1]:

**Lemma 4.3.** Let $V, W$ be $L^\infty$ matrix functions on $\mathbb{T}$, of types $n \times n$, $m \times m$ respectively, which are unitary-valued a.e. and are of the form

$$
V = \begin{pmatrix}
v & V_c
\end{pmatrix}, \quad W = \begin{pmatrix}
w & W_c
\end{pmatrix},
$$

where $v, V_c, w, W_c$ are $H^\infty$ matrix functions, $v$ and $w$ are column functions, and $V_c, W_c$ are co-outer. Then

$$W H^\infty(M_{m,n}) V \cap \big( \begin{pmatrix}
\begin{pmatrix}
0 & 0 \\
0 & L^\infty(M_{m-1,n-1})
\end{pmatrix}
\end{pmatrix} = \begin{pmatrix}
\begin{pmatrix}
0 & 0 \\
0 & H^\infty(M_{m-1,n-1})
\end{pmatrix}
\end{pmatrix}.
$$

Proof of Theorem 4.2. Let $Q$ be an optimal solution. By Lemma 4.1

$$W \begin{pmatrix}
\begin{pmatrix}
Q_0 - Q & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\end{pmatrix} V
$$

has the form

$$
\begin{pmatrix}
\begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\end{pmatrix} 
\begin{pmatrix}
\begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\end{pmatrix}
$$

(the upper left block is scalar). On the other hand it is easy to see from the definition of $V$ and $W$ (see Section 3) that

$$W \begin{pmatrix}
\begin{pmatrix}
Q_0 - Q & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\end{pmatrix} V = \begin{pmatrix}
\begin{pmatrix}
w_1 & W_c f(Q_0 - Q) \begin{pmatrix}
v_1 & V_c
\end{pmatrix} & 0
\end{pmatrix}
\end{pmatrix} \begin{pmatrix}
\begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\end{pmatrix}.$$

Therefore
\[
\begin{pmatrix}
  w_1 & W_c
\end{pmatrix}^t (Q_0 - Q) \begin{pmatrix}
  v_1 & V_c
\end{pmatrix} = \begin{pmatrix}
  \emptyset & \emptyset \\
  \emptyset & F
\end{pmatrix}
\]
for some \( F \in L^\infty(M_{m_1-1,n_1-1}) \) (the upper left corner of the matrix function on the right hand side is scalar). Let \( v_1 = v(o)v(i) \), \( w_1 = w(o)w(i) \), where \( v(o) \) and \( w(o) \) are scalar outer functions, and \( v(i) \) and \( w(i) \) are inner column functions. We have
\[
\begin{pmatrix}
  w_1 & W_c
\end{pmatrix}^t (Q_0 - Q) \begin{pmatrix}
  v_1 & V_c
\end{pmatrix} = \begin{pmatrix}
  \emptyset & \emptyset \\
  \emptyset & I
\end{pmatrix} \begin{pmatrix}
  \emptyset & \emptyset \\
  \emptyset & F
\end{pmatrix} \begin{pmatrix}
  v_1 & V_c
\end{pmatrix} = \begin{pmatrix}
  \emptyset & \emptyset \\
  \emptyset & I
\end{pmatrix}.
\]

Put \( v = v(i) \), \( w = w(i) \). Clearly, the matrix functions \( V = \begin{pmatrix} v & V_c \end{pmatrix} \) and \( W = \begin{pmatrix} w & W_c \end{pmatrix} \) satisfy the hypotheses of Lemma 4.3. Therefore \( F \in H^\infty(M_{m_1-1,n_1-1}) \), which proves that \( Q \) satisfies (4.3) with \( Q_1 = -F \). Since \( Q \) is an optimal solution, (4.4) obviously holds.

Conversely, suppose that \( Q_1 \) is a function in \( H^\infty(M_{m_1-1,n_1-1}) \) satisfying (4.3). Then it follows from Lemma 4.3 that there exists a function \( G \in H^\infty(M_{m_1,n_1}) \) such that
\[
\begin{pmatrix}
  w_1 & W_c
\end{pmatrix}^t G \begin{pmatrix}
  v_1 & V_c
\end{pmatrix} = \begin{pmatrix}
  \emptyset & \emptyset \\
  \emptyset & -Q_1
\end{pmatrix},
\]
which implies that
\[
\begin{pmatrix}
  \Phi_{11} - (G + Q_0) & \Phi_{12} \\
  \Phi_{21} & \Phi_{22}
\end{pmatrix} = W^* \begin{pmatrix}
  t_0 u_0 & \emptyset & \emptyset \\
  \emptyset & \Phi^{(1)}_{11} - Q_1 & \emptyset \\
  \emptyset & \Phi^{(1)}_{21} & \Phi^{(1)}_{22}
\end{pmatrix} V^*
\]
and so \( Q = G + Q_0 \in H^\infty(M_{m_1,n_1}) \). Clearly, (4.4) implies now that \( Q \) is an optimal solution.

It is easy to see that Theorem 4.2 reduces the problem of finding a superoptimal solution for \( \Phi \) to the same problem for the matrix function \( \begin{pmatrix} \Phi^{(1)}_{11} & \Phi^{(1)}_{12} \\
  \Phi^{(1)}_{21} & \Phi^{(1)}_{22} \end{pmatrix} \) which has a lower size.
5. The matrix functions $V_c$ and $W_c$ are left invertible in $H^\infty$

In the last section we reduced the problem of finding a superoptimal solution for $\Phi$ to the same problem for $\Phi^{(1)}$ defined by $\begin{pmatrix} \Phi^{(1)}_{11} \\ \Phi^{(1)}_{12} \\ \Phi^{(1)}_{21} \\ \Phi^{(1)}_{22} \end{pmatrix}$. If we could continue this process, we would eventually reduce the problem to the case $\min\{m_1, n_1\} = 1$ and it would follow from Corollary 3.3 that there is a unique superoptimal solution to the four block operator problem for $\Phi$. The main problem now is to prove that the four block operator follows from Corollary 3.4 that there is a unique superoptimal solution to the four block operator problem for $\Phi$.

In this section we shall prove that the matrix functions $V_c$ and $W_c$ are left invertible in $H^\infty$ (in other words the corona problem is solvable for them) which we shall use in the next section to prove that $\|\Gamma_{\Psi_1}\|_e \leq \|\Phi\|_e$.

**Theorem 5.1.** If $\|\Phi\|_e < \|\Gamma_{\Psi_1}\|_e$, then the matrix functions $V_c$ and $W_c$ defined in Section 3 are left invertible in $H^\infty$.

Clearly, it is sufficient to prove that $W_c$ is left invertible in $H^\infty$, which means that there exists a matrix function $\Omega$ in $H^\infty(M_{m_1,n_1-1})$ such that $\Omega(\zeta)W_c(\zeta) = I$ for every $\zeta \in \mathbb{D}$. To show the left invertibility of $V_c$, it is sufficient to apply Theorem 5.1 to the transposed function $\Phi^t$ and use the equalities $\|\Gamma_{\Phi}\|_e = \|\Gamma_{\Phi^t}\|_e$ and $\|\Phi\|_e = \|\Gamma_{\Phi^t}\|_e$, which follow immediately from the obvious identity $\Gamma_{\Phi^t} = J\Gamma_{\Psi}^* J$.

Recall that $\overline{w} = \overline{w}_1 \oplus \overline{w}_2$ is the first column of $W^*$. Denote by $w_{1r}$, $1 \leq r \leq n_1$, the components of $w_1$. We have $w_1 = w_{(o)}w_{(i)}$, where $w_{(o)}$ is a scalar outer function in $H^2$ and $w_{(i)}$ is an inner column function.

**Lemma 5.2.** The vectorial Toeplitz operator $T_{\overline{w}} : H^2 \rightarrow H^2(\mathbb{C}^{n_1})$ is left invertible.

**Proof.** First of all, $\text{Ker} T_{\overline{w}_1} = \{0\}$. Indeed, assume that $\psi \in \text{Ker} T_{\overline{w}_1}$. Then $\overline{w}_1, \psi \in H^2$ for $1 \leq r \leq n_1$. Since 1 is a greatest inner divisor of the components of $w_1$, it follows from Beurling’s theorem that the functions $\{\sum_{r=1}^{n_1} \kappa_r w_{1r} : \kappa_r \in H^2\}$ form a dense subset in $H^2$. Therefore we can approximate $\psi$ in the $L^1$-norm by functions of the form $\sum_{r=1}^{n_1} \kappa_r \overline{w}_1, \psi$, each of which belongs to $H^1_\psi$ defined by $\{\varphi \in L^1 : \varphi(k) = 0$ for $k \geq 0\}$. Hence $\psi \in H^1_\psi$ and since $\psi \in H^2$, it follows that $\psi = 0$. 

---

1. Vladimir V. Peller and Sergei R. Treil
2. Theorem 5.1.
3. [PY2]
4. Lemma 5.2.
If $T_{w_1}$ is not left invertible, there exists a sequence of scalar functions $\{\varphi_j\}_{j \geq 0}$ in $H^2$ such that $\|\varphi_j\| = 1$ and $\varphi_n \to o$ in the weak topology and $\|T_{w_1} \varphi_n\| \to 0$. By Lemma 4.1 the operator $T_{w_0}$ is onto and so there exists a sequence $\{\omega_n\}_{n \geq 0}$ of scalar functions in $(\text{Ker } T_{w_0})^\perp$ such that $T_{w_0} \omega_n = \varphi_n$. Since $T_{w_0}$ is Fredholm, $\omega_n \to o$ weakly.

Put $\rho_n \overset{\text{def}}{=} \omega_n v \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2})$, where $v$ is the first column of $V$. Let $Q_0$ be an optimal solution of the four block problem for $\Phi$. By (1.1) we have

$$
\begin{pmatrix}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{pmatrix}
\begin{pmatrix}
\rho_j
\end{pmatrix}
= W^*
\begin{pmatrix}
t_0 u_0 \omega_j \\
\vdots
\end{pmatrix}
= t_0 u_0 \omega_j \overline{w} = t_0 (\varphi_j + \varphi_j^{-} \overline{w}),
$$

for some functions $\varphi_j^{-} \in H^2$. It follows that

$$
\|\Gamma_{\Phi} \rho_j\|^2 = \|P^- \begin{pmatrix}
\Phi_{11} - Q_0 & \Phi_{12} \\
\Phi_{21} & \Phi_{22}
\end{pmatrix} \begin{pmatrix}
\rho_j
\end{pmatrix}\|^2 = \|t_0 P^- (\varphi_j + \varphi_j^{-} \overline{w})\|^2
$$

$$
= \|t_0 (\varphi_j + \varphi_j^{-} \overline{w})\|^2 - \|P+ t_0 (\varphi_j + \varphi_j^{-} \overline{w})\|^2
$$

$$
= \|t_0 u_0 \omega_j \overline{w}\|^2 - \|t_0 P+ \varphi_j \overline{w}\|^2
$$

$$
= \|t_0 u_0 \omega_j \overline{w}\|^2 - \|t_0 P+ \varphi_j \overline{w}\|^2 = t_0^2 (\|\rho_j\|^2 - \|T_{w_1} \varphi_j\|^2),
$$

since $\|v(\zeta)\|_{C_{n_1}} = \|w(\zeta)\|_{C_{n_1}}$.

Taking into account that $\|T_{w_1} \varphi_j\| \to 0$ and $\rho_j \to o$ weakly, we obtain $\|\Gamma_{\Phi}\|_e = t_0 = \|\Gamma_{\Phi}\|$ which contradicts the hypotheses of the lemma. ■

The next step is to prove that the Toeplitz operator $T_{w_1}$ is left invertible, where $w(i)$ is the inner part of $w_1$. We need the following well known facts. Let $\chi = \{\chi_j\}_{1 \leq j \leq k}$ be a column function in $H^\infty(\mathbb{C}^k)$. Then it is left invertible in $H^\infty$ (i.e. there exist functions $\kappa_j, 1 \leq j \leq k$, such that $\sum_{j=1}^k \kappa_j(\zeta) \chi_j(\zeta) = 1$ for all $\zeta \in \mathbb{D}$) if and only if the Toeplitz operator $T_\chi$ is left invertible (see [Ar]). Note that by the Carleson corona theorem (see e.g., [Ni]) $\chi$ is left invertible if and only if $\inf_{\zeta \in \mathbb{D}} \|\chi(\zeta)\|_{C_k} > 0$. This result was generalized in [SNF2] for the case of matrix (and even operator) functions: let $\Xi$ be a matrix function in $H^\infty$, then $\Xi$ is left invertible in $H^\infty$ if and only if the Toeplitz operator $T_{\Xi}$ is left invertible.

**Lemma 5.3.** Under the hypotheses of Theorem 5.1, the Toeplitz operator $T_{w_1}$ is left invertible.

**Proof.** By Lemma 5.2, $T_{w_1}$ is left invertible. By Arveson’s theorem mentioned above $w_1$ is left invertible in $H^\infty$. We have $w_1 = w(i) w(i)$, where $w(i)$ is a scalar outer function in $H^\infty$ and $w(i)$ is an inner column function. Obviously, it follows that $w(i)$ is left invertible in $H^\infty$. Again by Arveson’s theorem this implies that $T_{w(i)}$ is left invertible. ■

We need the following result proved in [P].
Theorem 5.4. Let $W$ be a unitary-valued matrix function of the form $W^t = \left( \begin{array}{c} w \new W_c \end{array} \right)$, where $w$ is a co-outer inner column, and $W_c$ is a co-outer inner function. Then the Toeplitz operator $T_{W^t}$ has trivial kernel and dense range, and the operators $H_{W^t}, H_{W^t}$ and $H_{(W^t)^*}, H_{(W^t)^*}$ are unitarily equivalent.

The following result can easily be deduced from Theorem 5.4.

Theorem 5.5. Let $W$ be a matrix function satisfying the hypotheses of Theorem 5.4. Suppose that $\|H_{w^t}\| < 1$. Then the Toeplitz operator $T_{W^t}$ is invertible.

Proof. Clearly, $\|H_{(W^t)^*}\| = \|H_{w^t}\| = \|H_{w}\| < 1$. By Theorem 5.4 the operators $H_{W^t}, H_{W^t}$ and $H_{(W^t)^*}, H_{(W^t)^*}$ are unitarily equivalent. Therefore $\|H_{W^t}\| = \|H_{(W^t)^*}\| < 1$. Since $W^t$ takes isometric values on $\mathbb{T}$, it is easy to see that

$$\|T_{W^t} F\|_2^2 + \|H_{W^t} F\|_2^2 = \|W^t F\|_2^2 = \|F\|_2^2$$

for every vector function $F$. Consequently, $T_{W^t}$ is left invertible if and only if $\|H_{W^t}\| < 1$. It follows that both $T_{W^t}$ and $T_{(W^t)^*}$ are left invertible which means that $T_{W^t}$ is invertible. ■

Proof of Theorem 5.1. Put $w \overset{\text{def}}{=} w^t$ and let $W^t = \left( \begin{array}{c} w^t \new W_c \end{array} \right)$. By Lemma 5.3, $T_{w^t}$ is left invertible. Since $w^t$ takes isometric values on $\mathbb{T}$, we have as in the proof of Theorem 5.5

$$\|T_{w^t} \omega\|^2 + \|H_{w^t} \omega\|^2 = \|\omega\|^2$$

for every $\omega \in H^2$. Hence $\|H_{w^t}\| < 1$ and so by Theorem 5.5 the operator $T_{W^t}$ is invertible. Clearly, it follows that $T_{w^t}$ is left invertible, since $T_{w^t}$ can be interpreted as a restriction of $T_{W^t}$. Therefore by the Sz.-Nagy–Foias theorem mentioned above $W_c$ is left invertible in $H^\infty$. ■

6. The Essential Norm of $\Gamma_{\Phi^t}$

In Section 4 we reduced the proof of Theorem 2.1 to the fact that $\|\Gamma_{\Phi^t}\|_e \leq \|\Gamma_{\Phi}\|_e$, where the matrix function $\Phi^t = \left( \begin{array}{c} \Phi_{11}^t \new \Phi_{12}^t \\ \Phi_{21}^t \new \Phi_{22}^t \end{array} \right)$ is defined in (4.1). In this section we are going to use the facts that $V_c$ and $W_c$ are left invertible (see Section 5) to prove this inequality which will complete the proof of Theorem 2.1.

The idea behind the proof is the following. We use the fact that

$$\|\Gamma_{\Phi^t}\|_e = \inf \{\limsup_j \|\Gamma_{\Phi^t}\|_{\xi_j} \}$$
where the infimum is taken over all sequences \( \{ \xi_j \} \) in \( H^2(\mathbb{C}^{n_1-1}) \oplus L^2(\mathbb{C}^{n_2}) \) such that \( \| \xi_j \|_2 = 1 \) and \( \xi_j \to O \) weakly. Given such a sequence \( \{ \xi_j \} \) we construct another sequence \( \{ \rho_j \} \) in \( H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}) \) such that \( \| \rho_j \|_2 = 1 \), \( \rho_j \to O \) weakly and

\[
\limsup_j \| \Gamma \Phi \rho_j \|_2 \geq \limsup_j \| \Gamma \Phi (1) \xi_j \|_2.
\]

To this end we are going to use a construction which is similar to the one used in [PY2].

Let \( W \) be the unitary-valued matrix function constructed in Section 3. Consider the matrix \( W^* \) which has the form

\[
W^* = \begin{pmatrix}
\pi_1 & W_c & F \\
\pi_2 & O & G \\
\end{pmatrix}.
\]

Let \( \beta = \begin{pmatrix}
W_c & F \\
O & G
\end{pmatrix}. \tag{6.1} \]

To use a construction similar to the one given in [PY2], we have to find a left inverse of \( \beta \) of a special form. Recall that we have proved in Section 5 that \( W_c \) is left invertible in \( H^\infty \). Let \( W_c^l \) be an \( H^\infty \) left inverse of \( W_c \).

**Lemma 6.1.** Let \( \beta \) be the matrix function defined by (6.1). Then the matrix function \( G \) is invertible in \( L^\infty \) and there exists a bounded left inverse of \( \beta \) of the form

\[
B = \begin{pmatrix}
W_c^l & X \\
O & G^{-1}
\end{pmatrix}. \tag{6.2}
\]

**Proof.** Suppose that \( G \) is not invertible in \( L^\infty \). Then there exists a sequence \( \{ \xi_j \}_{j \geq 0} \) in \( L^2(\mathbb{C}^{m_2}) \) such that \( \| \xi_j \|_2 = 1 \) and \( \| G \xi_j \|_2 \to 0 \).

It is easy to see from Lemma 3.3 that

\[
\| w_1(\zeta) \|_{\mathbb{C}^{m_1}}^2 \geq \frac{\| \Gamma \Phi \|_e^2 - \| \Gamma \Phi \|_e^2}{\| \Gamma \Phi \|_e^2} \overset{\text{def}}{=} \delta < 1, \ \zeta \in \mathbb{T}. \tag{6.3}
\]

Since the column \( \eta_1(\zeta) \) is orthogonal to the columns of \( W_c(\zeta) \) a.e. on \( \mathbb{T} \), it follows that the matrix function \( \begin{pmatrix}
\pi_1 & W_c
\end{pmatrix} \) is invertible in \( L^\infty \). Therefore there exists a bounded sequence \( \{ \eta_j \} \) in \( L^2(\mathbb{C}^{m_1}) \) such that

\[
\begin{pmatrix}
\pi_1 & W_c
\end{pmatrix} \eta_j + F \xi_j = O.
\]

Then

\[
W^* \begin{pmatrix}
\eta_j \\
\xi_j
\end{pmatrix} = \begin{pmatrix}
\pi_2 & O
\end{pmatrix} \eta_j + G \xi_j.
\]
It follows from (6.3) that $\|w_2(\zeta)\|_{C^m_2}^2 \leq 1 - \delta$, $\zeta \in \mathbb{T}$. Since $\|G\xi\|_2 \to 0$, we have for large values of $j$
\[ \left\| W^* \begin{pmatrix} \eta_j \\ \xi_j \end{pmatrix} \right\|_2 < \left\| \eta_j \right\|_2 \leq \left\| \begin{pmatrix} \eta_j \\ \xi_j \end{pmatrix} \right\|_2, \]
which contradicts the fact that $W$ is unitary-valued.

Let now $B$ be a matrix in the form (6.2). Clearly $B\beta = I$ if and only if
\[ W^* F + XG = 0. \]
Since $G$ is invertible in $L^\infty$, we can always find a matrix function $X$ in $L^\infty$ which satisfies this equality.

**Remark.** In the same way we can consider the submatrix $\alpha$ of the matrix $V$ constructed in Section 3,
\[ \alpha = \begin{pmatrix} V_c & * \\ \mathbf{0} & * \end{pmatrix} \]
and prove that $\alpha$ has a left inverse in the form
\[ A = \begin{pmatrix} V^\text{li}_c & * \\ \mathbf{0} & * \end{pmatrix}, \]
where $V^\text{li}_c$ is an $H^\infty$ left inverse of $V_c$.

To prove the main result of this section we need the following lemma which in the case of Nehari’s problem was proved in [PY2] (see Lemma 2.1 there).

**Lemma 6.2.** Let $\eta$ be a vector function in $H^2(\mathbb{C}^{m_1-1}) \oplus L^2(\mathbb{C}^{m_2})$ and let $\chi$ be the scalar function in $H^2$ defined by
\[ \chi = -P_+ w^t B^* \eta. \]
Then
\[ W^* \begin{pmatrix} \chi \\ \eta \end{pmatrix} \in H^2_-(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2}). \]

**Proof.** Since $W$ is unitary-valued, we have
\[ I = W^* W = \overline{w} w^t + \beta \beta^* \]
and hence
\[ \beta = \beta(B\beta)^* = \beta \beta^* B^* = (I - \overline{w} w^t) B^*. \]

Therefore
\[ W^* \begin{pmatrix} \chi \\ \eta \end{pmatrix} = \begin{pmatrix} \overline{w} & \beta \end{pmatrix} \begin{pmatrix} \chi \\ \eta \end{pmatrix} = \overline{w} \chi + (I - \overline{w} w^t) B^* \eta = B^* \eta + \overline{w}(\chi + w^t B^* \eta). \]

It is easy to see from (6.2) that $B^* \eta \in H^2_-(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$. Since $w \in H^\infty(\mathbb{C}^{m_1}) \oplus L^\infty(\mathbb{C}^{m_2})$, it follows that $\overline{w}(\chi + w^t B^* \eta) = \overline{w} P_- w^t B^* \eta \in H^2_-$, which proves the result.

\[ \blacksquare \]
Remark. It is easy to see that if \( \{ \eta_j \} \) is a sequence of functions in \( H^2(\mathbb{C}^{m_1-1}) \oplus L^2(\mathbb{C}^{m_2}) \) which converges weakly to \( \emptyset \), the above construction produces a sequence of scalar functions \( \{ \chi_j \} \) in \( H^2 \), \( \chi_j = -\mathbb{P}_+(w^TB^*\eta_j) \), which also converges weakly to \( \emptyset \).

Now we are in a position to prove that \( \| \Gamma_{\Phi_1} \|_e \leq \| \Gamma_{\Phi} \|_e \), where the matrix function \( \Phi^{(1)} = \begin{pmatrix} \Phi_{11}^{(1)} & \Phi_{12}^{(1)} \\ \Phi_{21}^{(1)} & \Phi_{22}^{(1)} \end{pmatrix} \) is defined in (4.1).

**Theorem 6.3.** Let \( \Phi \) be a matrix function of the form (2.1) such that \( \| \Gamma_{\Phi} \|_e \leq \| \Gamma_{\Phi(1)} \|_e \leq \| \Gamma_{\Phi} \|_e \).

**Proof.** Let \( \{ \xi_j \} \) be a sequence of functions in \( H^2(\mathbb{C}^{n_1-1}) \oplus L^2(\mathbb{C}^{n_2}) \) such that \( \| \xi_j \|_2 = 1 \) and \( \xi_j \to \emptyset \) weakly. Put \( \eta_j = \Gamma_{\Phi(1)}\xi_j \). We are going to construct a sequence of functions \( \{ \xi_j^\# \} \) in \( H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}) \) such that \( \frac{\xi_j^\#}{\| \xi_j^\# \|_2} \to \emptyset \) weakly, and \( \frac{\| \eta_j^\# \|_2}{\| \xi_j^\# \|_2} \geq \| \eta_j \|_2 \), where \( \eta_j^\# \overset{\text{def}}{=} \Gamma_{\Phi}\xi_j^\# \). As we have explained in the beginning of the section, this would imply the desired inequality (put \( \rho_j = \frac{\xi_j^\#}{\| \xi_j^\# \|_2} \)).

To this end we apply Lemma 5.2 to the sequence \( \{ \eta_j \} \). We obtain a sequence of scalar \( H^2 \) functions \( \{ \chi_j \} \) such that

\[
W^* \begin{pmatrix} \chi_j \\ \eta_j \end{pmatrix} \in H^2_-(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2}).
\]

Put

\[
\xi_j^\# = A^t\xi_j + q_jv,
\]

where \( v \) is the first column of \( V \) and \( A \) is the left inverse of \( \alpha \) described in the Remark after Lemma 5.1. The scalar functions \( q_j \) will be chosen later.

We have

\[
\begin{pmatrix} t_0u_0 & \emptyset \\ \emptyset & \Phi^{(1)} \end{pmatrix} V^*\xi_j^\# = \begin{pmatrix} t_0u_0q_j + t_0u_0v^*A^t\xi_j \\ \Phi^{(1)}\xi_j \end{pmatrix}.
\]

Since the Toeplitz operator \( T_{u_0} \) is onto, we can pick \( q_j \) as a solution of the equation

\[
\mathbb{P}_+(t_0u_0q_j + t_0u_0v^*A^t\xi_j) = \chi_j.
\]

Clearly, we may choose the \( q_j \) so that \( q_j \to \emptyset \) weakly. Indeed, we may put

\[
q_j = t_0^{-1}(T_{u_0}((\text{Ker} T_{u_0})^\perp)^{-1}(t_0\chi_j - \mathbb{P}_+u_0v^*A^t\xi_j)).
\]

It follows that \( \xi_j^\# \to \emptyset \) weakly.

Let us show that the sequence \( \{ \xi_j^\# \} \) has the required properties. Since \( \xi_j^\# \to \emptyset \) weakly, to prove that \( \frac{\xi_j^\#}{\| \xi_j^\# \|_2} \to \emptyset \) weakly, we have to estimate \( \| \xi_j^\# \|_2 \) from below. We
have

$$
\|\xi_j^\#\|_2^2 = \|V^*\xi_j^\#\|_2^2 = \|q^*_j + v^* A^t \xi_j\|_2^2 + \|\xi_j\|_2^2 \geq 1. \quad (6.5)
$$

To complete the proof it remains to show that

$$
\|\Gamma \Phi \xi_j^\#\|_2 \geq \|\eta_j\|_2.
$$

Recall that $\eta_j = \Gamma \Phi(1) \eta_j = P^- \Phi(1) \xi_j$ and so $\Phi(1) \xi_j - \eta_j \in H^2(\mathbb{C}^{m_1 - 1}) \oplus \{0\}$. It is easy to see from the definition of $W$ (see Section 3) that

$$
W^* \begin{pmatrix} \emptyset \\ \Phi(1) \xi_j - \eta_j \end{pmatrix} \in H^2(\mathbb{C}^{m_1}) \oplus \{0\}.
$$

It follows now from (6.4) that

$$
\eta_j^\# = P^- \Phi \xi_j^\# = P^- W^* \begin{pmatrix} t_0 u_0 \\ \emptyset \end{pmatrix} \Phi(1) V^* \xi_j^\# = P^- W^* \begin{pmatrix} \chi_j + \omega_j \\ \eta_j \end{pmatrix},
$$

where

$$
\omega_j \overset{\text{def}}{=} P_- (t_0 u_0 q_j + t_0 u_0 v^* A^t \xi_j).
$$

Since the first column of $W^*$ is $w_1 \oplus w_2$ and $w_1 \in H^\infty$, it follows that

$$
W^* \begin{pmatrix} \omega_j \\ \emptyset \end{pmatrix} \in \begin{pmatrix} H^2(\mathbb{C}^{m_1}) \\ L^2(\mathbb{C}^{m_2}) \end{pmatrix}.
$$

We have chosen $\{\chi_j\}$ so that

$$
W^* \begin{pmatrix} \chi_j \\ \eta_j \end{pmatrix} \in \begin{pmatrix} H^2(\mathbb{C}^{m_1}) \\ L^2(\mathbb{C}^{m_2}) \end{pmatrix}.
$$

Therefore

$$
P^- W^* \begin{pmatrix} \chi_j + \omega_j \\ \eta_j \end{pmatrix} = W^* \begin{pmatrix} \chi_j + \omega_j \\ \eta_j \end{pmatrix}.
$$

Hence

$$
\|\eta_j^\#\|_2^2 = \|\chi_j + \omega_j\|_2^2 + \|\eta_j\|_2^2 = t_0^2 \|q_j + v^* A^t \xi_j\|_2^2 + \|\Gamma \Phi(1) \xi_j\|_2^2.
$$

Since $\|\Gamma \Phi(1)\| \leq t_0$, this together with (6.3) yields

$$
\frac{\|\eta_j^\#\|_2^2}{\|\xi_j^\#\|_2^2} > \frac{\|\eta_j\|_2}{\|\xi_j\|_2} = \|\eta_j\|_2,
$$

which completes the proof. ■

As we have already explained, Theorem 6.3 allows us to complete the proof of Theorem 2.1.

**Proof of Theorem 2.1.** By Theorem 4.2 the four block for $\Phi$ has a unique solution if so does the four block problem for $\Phi(1)$ and the superoptimal singular values of the four block problem for $\Phi(1)$ are $t_1, t_2, \cdots, t_{d-1}$. By Theorem 6.3, $\|\Gamma \Phi(1)\|_e \leq \|\Gamma \Phi\|_e$. If $\Gamma \Phi(1) = \emptyset$, we certainly have uniqueness. Otherwise we can continue this process.
Doing in this way we may stop the process if we get on a certain stage the zero four block operator or, otherwise, we eventually reduce the problem to the case \( d = 1 \). Uniqueness follows now from Corollary 3.4.

The fact that the singular values are constant on \( \mathbb{T} \) follows immediately from the facts that \( V \) and \( W \) are unitary-valued and \( u_0 \) is unimodular, and from Lemma 3.2.

\[ \square \]

### 7. Thematic factorizations and indices of superoptimal singular values

In this section we analyze the algorithm described in Section 3 and obtain certain special factorizations of superoptimal symbols of four block operators satisfying the hypotheses of Theorem 2.1. Following [PY1] we shall call such factorizations thematic.

In Section 3 we have constructed matrix functions \( V \) and \( W \) associated with the four block problem. By analogy with [PY1] we shall call matrix functions of the form \( V \) or \( W \) thematic functions.

To state the result we may assume without loss of generality that \( n_1 \leq m_1 \) (otherwise we can take the transpose).

**Theorem 7.1.** Let \( \Phi \) be a superoptimal symbol of the four block operator \( \Gamma \) which satisfies the hypotheses of Theorem 2.1 and suppose that \( n_1 \leq m_1 \). Then \( \Phi \) admits the following factorization

\[
\Phi = W_0^* W_1^* W_2^* \cdots W_{d-1}^* D V_{d-1}^* \cdots V_2^* V_1^* V_0^*,
\]

where

\[
D = \begin{pmatrix}
t_0 u_0 & \cdots & \cdots & \cdots \\
\odot & t_1 u_1 & \cdots & \cdots \\
\vdots & \vdots & \ddots & \vdots \\
\odot & \odot & \cdots & t_{d-1} u_{d-1} \\
\vdots & \vdots & \ddots & \vdots \\
\odot & \odot & \cdots & \odot
\end{pmatrix}
\]

the \( u_j \) are unimodular functions such that the Toeplitz operator \( T_{u_j} \) is Fredholm and \( \text{ind} T_{u_j} > 0 \), and the matrix functions \( W_j \) and \( V_j \) have the form

\[
V_j = \begin{pmatrix}
I_j & 0 \\
0 & \tilde{V}_j
\end{pmatrix}, \quad W_j = \begin{pmatrix}
I_j & 0 \\
0 & \tilde{W}_j
\end{pmatrix},
\]

where \( \tilde{V}_j, \tilde{W}_j \) are thematic matrix functions and \( I_j \) is the identity \( j \times j \) matrix.
It is easy to see that the successive application of the algorithm described in Section 3 gives us a desired factorization.

**Remark.** As in the case of Nehari’s problem (see [PY1]) it is easy to see that if a matrix function admits a factorization of the form (7.1), then it is the superoptimal symbol of the corresponding four block operator.

We can associate with the factorization (7.1) the *factorization indices* $k_j$ which are defined in the case $t_j \neq 0$. We put $k_j = \text{ind} T_{u_j} = \dim \text{Ker} T_{u_j}$.

It was shown in [PY1] that even for Nehari’s problem the indices depend on the choice of a thematic factorization rather than on the function $\Phi$ itself. However, it was shown in [PY2] that for Nehari’s problem with compact Hankel operator the sum of the indices corresponding to equal superoptimal singular values is an invariant (i.e. does not depend on the choice of a factorization).

The same turns out to be true for the four block problem too, and we shall prove this later in Section 9. Moreover, the sum of the indices corresponding to equal superoptimal singular values admits a quite natural and simple geometric interpretation. To give this interpretation we have to introduce a new object — the so-called *superoptimal weight*. 
Superoptimal weight

Let \( W \in L^\infty(M_{n,n}) \) be a matrix weight, i.e. a bounded matrix-valued function on \( T \), whose values are nonnegative selfadjoint \( n \times n \) matrices.

Given a four block operator \( \Gamma : H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}) \to H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2}), n_1+n_2 = n \), we call a weight \( W \) admissible if

\[
\| \Gamma f \|^2 \leq (Wf, f) \quad \text{def} = \int_T (W(\zeta)f(\zeta), f(\zeta))d\mu(\zeta), \quad f \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}).
\]

We need the following result which we call Generalized Nehari’s Theorem.

**Theorem 8.1.** Given a four block operator \( \Gamma \Phi \) and an admissible weight \( W \) there exists a symbol \( \Phi \) of \( \Gamma \) (i.e. an operator-valued function \( \Phi \) such that \( \Gamma = \Gamma \Phi \)) satisfying \( \Phi^* \Phi \leq W \).

If \( \Phi \) is a symbol of \( \Gamma \) satisfying \( \Phi^* \Phi \leq W \), we say that \( \Phi \) is dominated by the admissible weight \( W \).

In the case \( W \equiv cI, \ v \in \mathbb{R}_+ \), this result was established in [FT], and this is an analog of Nehari’s theorem for four block operators. In the general case the result follows from Theorem 1.1 of [TV], since the four block operator \( \Gamma \) acting from the space \( H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}) \) endowed with the weighted norm \( \| \cdot \|_W \) to the space \( H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2}) \) satisfies the hypothesis of the theorem.

For the sake of completeness we deduce Theorem 8.1 from the analog of Nehari’s theorem mentioned above.

**Proof of theorem 8.1.** Define \( W_\varepsilon = W + \varepsilon I \). Since \( W_\varepsilon \geq \varepsilon I \), it admits a factorization \( W_\varepsilon = G_\varepsilon^* G_\varepsilon \), where \( G_\varepsilon \in H^\infty(M_{n,n}) \) is a matrix function which is invertible in \( H^\infty \) (see [R]). The weight \( W_\varepsilon \) is clearly admissible, so

\[
\| \Gamma f \| \leq \| G_\varepsilon f \|, \quad f \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}),
\]

which is equivalent to the fact that

\[
\| \Gamma G_\varepsilon^{-1} f \| \leq \| f \|, \quad f \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2}),
\]

Since \( G_\varepsilon^{-1} \in H^\infty(M_{n,n}) \), we can consider the operator \( \Gamma G_\varepsilon^{-1} \) as a four block operator. By the analog of Nehari’s theorem it has a symbol \( \Psi_\varepsilon \) such that \( \| \Psi_\varepsilon \|_\infty \leq 1 \). Then the function \( \Phi_\varepsilon = \Psi G_\varepsilon \) is a symbol of \( \Gamma \) and

\[
\Phi^* \Phi_\varepsilon = G_\varepsilon^* \Psi^* \Psi G_\varepsilon \leq G_\varepsilon^* G_\varepsilon = W_\varepsilon = W + \varepsilon I.
\]

It remains to chose a sequence \( \{ \varepsilon_j \} \) converging to 0 and such that the sequence \( \{ \Phi_{\varepsilon_j} \} \) converges to a matrix function, say \( \Phi \in L^\infty \), in the \(*\)-weak topology. Clearly, \( \Phi \) is a symbol of \( \Gamma \) dominated by \( W \).
Definition. Let $W$ be an admissible weight for the four block operator $G$. Consider the numbers
\[ s_j^\infty(W) \overset{\text{def}}{=} \text{ess sup}_{\zeta \in T} s_j(W(\zeta)), \quad 0 \leq j \leq d - 1, \quad d = \min\{m_1, n_1\}. \]

The admissible weight $W$ is called superoptimal if it lexicographically minimizes the numbers $s_0^\infty(W), s_1^\infty(W), \ldots, s_{d-1}^\infty(W)$ among all admissible weights, i.e.,
\[ s_0^\infty(W) = \min\{s_0^\infty(V) : V \text{ is admissible}\}, \]
\[ s_1^\infty(W) = \min\{s_1^\infty(V) : V \text{ is admissible}, s_0^\infty(V) \text{ is minimal possible}\}, \text{ etc.} \]

The following lemma shows that under the hypotheses of Theorem 2.1 a superoptimal weight exists. However, a superoptimal weight is not unique in general. The lemma also shows that a superoptimal weight is nevertheless "essentially" unique for our purposes.

Let $\lambda_a, a \in \mathbb{R}$, be the function on $\mathbb{R}$ defined by
\[ \lambda_a(t) \overset{\text{def}}{=} \begin{cases} 
  t, & t \geq a \\
  0, & t < a 
\end{cases}. \]

Lemma 8.2. Let $\Gamma$ be a four block operator satisfying the hypothesis of Theorem 3.3. Let $\Phi$ be the superoptimal symbol of $\Gamma$. Then
1. $\Phi^*\Phi$ is a superoptimal weight for $\Gamma$;
2. If $W$ and $W'$ are two superoptimal weights, then $\lambda_a(W) = \lambda_a(W')$ for any $a \geq t_{d-1}$.

Proof. Note that $\Phi$ is a symbol of $\Gamma$ dominated by the weight $\Phi^*\Phi$. Suppose that $\Phi^*\Phi$ is not a superoptimal weight, i.e. that there exists an admissible weight $W$ such that for some $j_0$, $0 \leq j_0 \leq d - 1$,
\[ s_{j_0}^\infty(W) < s_{j_0}^\infty(\Phi^*\Phi), \quad s_j^\infty(W) = s_j^\infty(\Phi^*\Phi), \quad 0 \leq j \leq j_0. \]

Let $\Psi$ be a symbol of $\Gamma$ dominated by the weight $W$. Then
\[ s_{j_0}^\infty(\Psi) < s_{j_0}^\infty(\Phi), \quad s_j^\infty(\Psi) = s_j^\infty(\Phi), \quad 0 \leq j \leq j_0, \]
which contradicts the fact that $\Phi$ is the superoptimal symbol of $\Gamma$. Therefore $\Phi^*\Phi$ is a superoptimal weight.

Let now $W$ be a superoptimal weight, and let $\Psi$ be a symbol of $\Gamma$ dominated by $W$. Then $\Psi$ lexicographically minimizes $(s_0^\infty(\Psi), s_1^\infty(\Psi), \ldots, s_{d-1}^\infty(\Psi))$ and so $\Psi$ coincides with the superoptimal symbol $\Phi$. So, for any superoptimal weight $W$ the superoptimal symbol $\Phi$ is the unique symbol of $\Gamma$ dominated by $W$. This means that $\Phi^*\Phi \leq W$ for any superoptimal weight $W$. Together with the equalities $s_j^\infty(W) = s_j^\infty(\Phi^*\Phi) = t_j^2$ this implies the second part of the lemma. □
Denote by $\Lambda_a$ the function defined by

$$
\Lambda_a(t) \overset{\text{def}}{=} \begin{cases} 
  t, & t \geq a \\
  a, & t < a
\end{cases}
$$

The following fact is an easy consequence of Lemma 8.2.

**Corollary 8.3.** Let $\mathcal{W}$ and $\mathcal{W}'$ be two superoptimal weights. Then $\Lambda_a(\mathcal{W}) = \Lambda_a(\mathcal{W}')$ for any $a \geq t_{d-1}$.

It is easy to see that if $a = t_{d-1}$ and $\mathcal{W}$ is a superoptimal weight, the weight $\Lambda_a(\mathcal{W})$ is the (unique) maximal superoptimal weight.

### 9. Invariance of indices

The main result of this section shows that the sum of the indices of a thematic factorization of a superoptimal symbol does not depend on the choice of a factorization. To prove this fact we shall use the same construction which was used in Section 6 to prove Theorem 6.3.

Let

$$a_0 > a_1 > \cdots > a_l$$

be all the distinct nonzero superoptimal singular values of a four block operator $\Gamma$ which satisfies the hypotheses of Theorem 7.1. Let $\Phi$ be the superoptimal symbol of $\Gamma$ and let $k_j$ be the indices of a thematic factorization of $\Phi$ of the form (7.1). Consider the sum of the indices that correspond to equal superoptimal singular values:

$$\nu_r = \sum_{\{j : t_j = a_r\}} k_j, \ 0 \leq r \leq l.$$ 

The following theorem is the main result of the section.

**Theorem 9.1.** The numbers $\nu_r$ do not depend on the choice of thematic factorization of $\Phi$.

We are going to deduce Theorem 9.1 from Theorem 9.3 below, which describes the numbers $\nu_r$ in terms of a superoptimal weight $\mathcal{W}$.

We say that a nonzero function $\xi \in H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$ is a maximizing vector for an admissible weight $\mathcal{W}$ if

$$\|\Gamma \xi\|^2 = (\mathcal{W} \xi, \xi).$$

**Lemma 9.2.** Let $\Gamma$ be a four block operator, $\mathcal{W}$ an admissible weight for $\Gamma$, and $\Phi$ a symbol of $\Gamma$ dominated by $\mathcal{W}$. Let $\xi$ be a maximizing vector for $\mathcal{W}$. Then $\Phi \xi \in H^2(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$, i.e., $\Gamma \Phi \xi = \Phi \xi$. 
Note that for \( W \equiv cI, \ c \in \mathbb{R}_+ \), this was proved in Lemma 3.2.

**Proof.** We have
\[
(W \xi, \xi) = \| \Gamma \Phi \xi \|_2^2 = \| P^\perp \Phi \xi \|_2^2 \leq \| \Phi \xi \|_2^2 \leq (W \xi, \xi).
\]
It follows that \( \| P^\perp \Phi \xi \|_2^2 \leq \| \Phi \xi \|_2^2 \), which implies the result. \( \blacksquare \)

Given an admissible weight \( W \) put
\[
E(W) = \{ \xi \in H^2(C^{n_1}) \oplus L^2(C^{n_2}) : \xi \text{ is maximizing for } W \text{ or } \xi = 0 \}.
\]
It is easy to see that \( \xi \in E(W) \) if and only if
\[
P^\perp W \xi - \Gamma_* \Phi \Gamma \Phi \xi = 0,
\]
where \( P^\perp \) is the orthogonal projection onto \( H^2(C^{n_1}) \oplus L^2(C^{n_2}) \). Therefore \( E(W) \) is a closed linear subspace. Recall that \( \Lambda_a(W) \) does not depend on the choice of superoptimal weight, where \( \Lambda_a \) is defined in (8.1).

**Theorem 9.3.** Let \( \Gamma \) be a four block operator satisfying the hypotheses of Theorem 2.1, \( W \) a superoptimal admissible weight, and \( \Phi \) the superoptimal symbol of \( \Gamma \).

Consider a thematic factorization of \( \Phi \) of the form (7.1). Let \( k_j \) be the indices of the factorization. Then for \( a \geq a_1 \),
\[
\sum_{\{j : t_j \geq a\}} k_j = \dim E(\Lambda_a(W)). \tag{9.1}
\]

Let us first deduce Theorem 9.1 from Theorem 9.3.

**Proof of theorem 9.1.** It follows immediately from (9.1) that
\[
\nu_0 = \dim E(\Lambda_{a_0}(W)), \ \nu_j = \dim E(\Lambda_{a_j}(W)) \ominus E(\Lambda_{a_{j-1}}(W)), \ 1 \leq j \leq l,
\]
which proves the result. \( \blacksquare \)

**Proof of Theorem 9.3.** It is easy to see that \( E(\Lambda_a(W)) \) is constant on \( (a_{j+1}, a_j) \).

So it is sufficient to prove that for \( 0 \leq s \leq l \)
\[
\sum_{\{j : t_j \geq a_s\}} k_j = \dim E(W_s),
\]
where \( W_s = \Lambda_{a_s}(W) \).

Let us prove the theorem by induction on \( d \).

If \( d = 1 \), factorization (7.1) has the form
\[
\Phi = W_0^* D V_0^*,
\]
where
\[
D = \begin{pmatrix}
  t_0 u_0 & 0 \\
  \vdots & 0 \\
  0 & 0 \\
  0 & * 
\end{pmatrix},
\]
and \( \| \ast \| < t_0 \) (otherwise the essential norm of \( \Gamma \Phi \) would not be less than \( t_0 \)). Clearly, \( W_0(\zeta) \equiv a_0 I \). If \( \xi \) is a maximizing vector for \( W_0 \), then it is easy to see that only the
first entry of $V_0^*\xi$ is nonzero. Therefore $\xi(\zeta)$ is pointwise orthogonal to all columns of $V$ except for the first one. It follows that $\xi = \chi v$, where $\chi$ is a scalar function in $L^2$. Using the fact that $v_1$ is a co-outer column function, one can easily deduce that $\chi \in H^2$. It is easy to see that

$$\Phi \xi = t_0u_0\chi \overline{\eta}.$$  

Since $\xi$ is a maximizing vector, it follows that $\Phi \xi \in H^2_1(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$. We can now use the fact that $w_1$ is a co-outer column function to deduce that $u_0\chi \in H^2$ which means that $\chi \in \text{Ker} T_{u_0}$.

Conversely, it is easy to see that if $\chi \in \text{Ker} T_{u_0}$, then $\xi = \chi v$ is a maximizing vector, which proves that $\dim \mathcal{E}(W_0) = \dim \text{Ker} T_{u_0} = k_0$.

Suppose now that the theorem is proved for $d-1$. We have

$$\Phi = W^* \left( \begin{array}{c} t_0u_0 \\ \Phi^{(1)} \end{array} \right) V^*,$$

where $\Phi^{(1)}$ is the superoptimal symbol of $\Gamma_{\Phi^{(1)}}$, $W \overset{\text{def}}{=} W_0$, and $V \overset{\text{def}}{=} V_0$. The induction hypothesis implies that the theorem holds for $\Gamma_{\Phi^{(1)}}$.

Let $0 \leq s \leq l$ and $a = a_s$. Suppose that $W'$ is a superoptimal weight for $\Gamma_{\Phi^{(1)}}$. By the induction hypothesis

$$\dim \mathcal{E}(\Lambda_a(\Lambda' \sigma)) = N \overset{\text{def}}{=} \sum_{\{j \geq 1: t_j \geq a\}} k_j,$$

where the $k_j$ are the indices of the thematic factorization (7.1). By Lemma 9.2, $\xi \in \mathcal{E}(\Lambda_a(\Lambda' \sigma))$ if and only if

$$\Phi^{(1)} \xi \in H^2_2(\mathbb{C}^{m_1-1}) \oplus L^2(\mathbb{C}^{m_2}) \quad \text{and} \quad \|\Phi^{(1)} \xi\|^2 = (\Lambda_a(\Lambda' \sigma) \xi, \xi).$$

Let $\xi_1, \xi_2, \ldots, \xi_N$ be a basis in $\mathcal{E}(\Lambda_a(\Lambda' \sigma))$ and let $\eta_1 = \Gamma_{\Phi^{(1)}}(\xi_1)$. By Lemma 6.2 there exist scalar functions $\chi_1, 1 \leq t \leq N$, such that

$$W^* \left( \begin{array}{c} \chi_t \\ \eta_t \end{array} \right) \in H^2_2(\mathbb{C}^{m_1-1}) \oplus L^2(\mathbb{C}^{m_2}).$$

As in the proof of Theorem 6.3 we define the functions $\xi^#_t$ as

$$\xi^#_t = A^t \xi_t + q_tv,$$

where $q_t$ is a scalar function in $H^2$ satisfying

$$\mathbb{P}_+(t_0u_0q_t + t_0u_0v^* A^t \xi_t) = \chi_t$$

(recall that the matrix function $A$ is defined in after Lemma 6.1). We have

$$\eta^#_t = \mathbb{P}^- \Phi \xi^#_t = \mathbb{P}^- W^* \left( \begin{array}{c} t_0u_0 \\ \Phi^{(1)} \end{array} \right) V^* \xi^#_t = \mathbb{P}^- W^* \left( \begin{array}{c} \chi_t + \omega_t \\ \eta_t \end{array} \right),$$

where as in the proof of Theorem 6.3

$$\omega_t = \mathbb{P}_-(t_0u_0q_t + t_0u_0v^* A^t \xi_t).$$
As we have explained in the proof of Theorem 6.3
\[ \mathbb{P}^{-} W^{*} \begin{pmatrix} x_{i} + \omega_{i} \\ \eta_{i} \end{pmatrix} = W^{*} \begin{pmatrix} x_{i} + \omega_{i} \\ \eta_{i} \end{pmatrix} \]
and so \( r_{i}^{#} = \Phi \xi_{i}^{#} \).

Since the matrix function \( W \) is unitary-valued, we have
\[
\| \Phi \xi_{i}^{#} \|^{2} = \left\| W^{*} \left( \begin{array}{c} t_{0}u_{0} \\ \Phi(1) \end{array} \right) \left( q_{i} + v^{*} A^{T} \xi_{i} \right) \right\|^{2} \\
= t_{0}^{2} \| u_{0}(q_{i} + v^{*} A^{T} \xi_{i}) \|^{2} + \| \Phi(1) \xi_{i} \|^{2} \\
= t_{0}^{2} \| q_{i} + v^{*} A^{T} \xi_{i} \|^{2} + (\Lambda(\mathcal{W}')) \xi_{i}, \xi_{i} \)
\]
(the last equality holds because \( \xi_{i} \in \mathcal{E}(\Lambda(\mathcal{W}')) \), where \( \mathcal{W}' = (\Phi(1))^{*} \Phi(1) \) is a superoptimal weight for \( \Gamma_{\Phi(1)} \).

Consider the weight \( \mathcal{V} \),
\[ \mathcal{V} = \left( \begin{array}{c} t_{0}^{2} \\ \Phi \end{array} \right) \left( \begin{array}{c} \Phi(1) \end{array} \right). \]

Bearing in mind that
\[ V^{*} \xi_{i}^{#} = \left( \begin{array}{c} q_{i} + v^{*} A^{T} \xi_{i} \\ \xi_{i} \end{array} \right), \]
we can continue the above chain of inequalities:
\[
\| \Phi \xi_{i}^{#} \|^{2} = (\Lambda(\mathcal{V}) V^{*} \xi_{i}^{#}, V^{*} \xi_{i}^{#}) \quad (9.2)
\]
(the last equality holds because \( V \) is unitary-valued). Since \( \Gamma_{\Phi \xi_{i}^{#}} = \mathbb{P}^{-} \Phi \xi_{i}^{#} = \Phi \xi_{i}^{#} \), it follows from (9.2) that \( \xi_{i}^{#} \in \mathcal{E}(\Lambda(\mathcal{W}')) \).

We can add now another \( k_{0} \) linear independent vectors of \( \mathcal{E}(\Lambda(\mathcal{W})) \). Let \( x_{1}, \ldots, x_{k_{0}} \) be a basis of \( \text{Ker} T_{u_{0}} \). Obviously, \( x_{i}, x_{j} \in \mathcal{E}(\Lambda(\mathcal{W})) \). Let us show that the vectors \( \xi_{1}^{#}, \ldots, \xi_{N}^{#}, x_{1}v, \ldots, x_{k_{0}}v \) are linearly independent. It is sufficient to prove that if \( x \in \text{Ker} T_{u_{0}} \) and \( x + \sum_{i=1}^{N} c_{i} \xi_{i}^{#} = \emptyset \), then \( x = \emptyset \) and \( c_{i} = 0, 1 \leq i \leq N \). We have
\[
V^{*}(x v + \sum_{i=1}^{N} c_{i} \xi_{i}^{#}) = \left( \begin{array}{c} x \\ \emptyset \end{array} \right) + \sum_{i=1}^{N} c_{i} \left( v^{*} A^{T} \xi_{i} + q_{i} \right) = \emptyset. \quad (9.3)
\]

Since the \( \xi_{i} \) are linearly independent, it follows that \( c_{i} = 0, 1 \leq i \leq N \), which in turn implies that \( x = \emptyset \).

This proves that
\[
\sum_{\left\{ j : t_{j} \geq a \right\}} k_{j} \leq \dim \mathcal{E}(\Lambda(\mathcal{W})).
\]
Let us prove the opposite inequality.

Denote by \( \mathcal{E}_{0} \) the set of vectors in \( \mathcal{E}(\Lambda(\mathcal{W})) \) of the form \( x v \) such that \( x \) is a scalar function in \( H^{2} \). It is easy to see that \( x v \in \mathcal{E}_{0} \) if and only if \( x \in \text{Ker} T_{u_{0}} \). It remains to
show that there exists at most $\sum_{j>0,t_j \geq a} k_j$ vectors $\tilde{\xi}_i$ that are linearly independent modulo $\mathcal{E}_0$. Let $\tilde{\eta}_i \overset{\text{def}}{=} \Gamma_\Phi \tilde{\xi}_i$. By Lemma 9.2, $\tilde{\eta}_i = \Phi \tilde{\xi}_i$. Put

$$V^* \tilde{\xi}_i = \left( \begin{array}{c} \gamma_j \\ \xi_i \end{array} \right), \quad W^* \tilde{\eta}_i = \left( \begin{array}{c} \delta_i \\ \eta_i \end{array} \right),$$

where $\gamma_i, \delta_i$ are scalar functions in $L^2$. Since the vectors $\tilde{\xi}_i$ are linearly independent modulo $\mathcal{E}_0$, the vectors $\xi_i$ are linearly independent. To complete the proof, it is sufficient to show that $\xi_i \in \mathcal{E}(\Lambda_a(W'))$.

Since $\tilde{\eta}_i = \Phi \tilde{\xi}_i$, we have that $\eta_i = \Phi^{(1)} \xi_i$ and $\delta_i = t_0 u_0 \gamma_i$. It follows from the block structure of $V$ and $W$ that $\xi_i \in H^2(\mathbb{C}^{m_1-1} \oplus L^2(\mathbb{C}^{n_2}))$ and $\eta_i \in H^2(\mathbb{C}^{m_1-1} \oplus L^2(\mathbb{C}^{m_2}))$. So $\eta_i = \Phi^{(1)} \xi_i$.

To show that $\xi_i \in \mathcal{E}(\Lambda_a(W'))$, consider the following chain of equalities

$$\left(\Lambda_a(W)\tilde{\xi}_i, \tilde{\xi}_i\right) = \left(\Lambda_a(VWV^*)V\tilde{\xi}_i, V\tilde{\xi}_i\right)$$

$$= \left((t_0^2 \oplus \Lambda_a(W')) \left( \begin{array}{c} \gamma_i \\ \xi_i \end{array} \right), \left( \begin{array}{c} \gamma_i \\ \xi_i \end{array} \right) \right)$$

$$= t_0^2 \|\gamma_i\|^2 + (\Lambda_a(W')\xi_i, \xi_i).$$

On the other hand

$$\left(\Lambda_a(W)\tilde{\xi}_i, \tilde{\xi}_i\right) = \|\Phi \tilde{\xi}_i\| = \|\tilde{\eta}_i\| = \|\eta_i\|^2 + \|\delta_i\|^2 = \|\Phi^{(1)} \xi_i\|^2 + t_0^2 \|\gamma_i\|^2.$$ 

Therefore $(\Lambda_a(W')\xi_i, \xi_i) = \|\Phi^{(1)} \xi_i\|^2$, which implies $\xi_i \in \Lambda_a(W')$. \[\blacksquare\]

10. Singular values of $\Gamma_\Phi$ and superoptimal singular values

Let $\Gamma$ be a four block operator satisfying the hypotheses of Theorem 2.1. Denote by $\Phi$ its unique superoptimal symbol and consider a thematic factorization of $\Phi$ of the form (7.4). Let $\{t_j\}$ be the superoptimal singular values and $\{k_j\}$ the indices of the factorization. Consider the extended $t$-sequence for $\Gamma$:

$$t_0, t_0, \ldots, t_1, \ldots, t_1, \ldots$$

in which $t_j$ is repeated $k_j$ times. We denote the terms of the extended sequence by $t_0', t_1', t_2', \ldots$. Although the indices $k_j$ depend on the choice of thematic factorization, it follows from Theorem 9.1 that the extended $t$-sequence is uniquely determined by $\Gamma$.

In [PY2] it was shown in the case of Nehari’s problem with $\Phi \in H^\infty + C$ that $t_j' \leq s_j(H_\Phi), 0 \leq j \leq k - 1$. In this section we are going to prove the same inequality in the case of the four block problem under the hypotheses of Theorem 2.1. Moreover,
we prove in this section a stronger result which is also new in the case of Nehari’s problem with an $H^\infty + C$ symbol. To prove the results we use in this section the same machinery as we used in Section 6.

Let $\Gamma$ be a four block operator that satisfies the hypotheses of Theorem 2.1. Then (see Section 3)

$$\Phi = W^* \left( t_0 u_0 \bigcirc \Phi(1) \right) V^*,$$

where the unitary-valued matrix functions $V$ and $W$ are defined in Section 3. The following inequality is the main result of the section.

**Theorem 10.1..** Let $\Gamma$ be a four block operator such that $\|\Gamma\|_e < \|\Gamma\|$ and let $\Phi$ be its superoptimal symbol. Then

$$s_j(\Gamma\Phi(1)) \leq s_{j+k_0}(\Gamma\Phi), \quad j \in \mathbb{Z}_+.$$

Recall that $k_0 = \dim \ker T_{u_0}$.

Let us first derive from Theorem 10.1 the desired inequality between the singular values of $\Gamma\Phi$ and the superoptimal singular values.

**Theorem 10.2..** Under the hypotheses of Theorem 2.1

$$t'_j \leq s_j(\Gamma\Phi), \quad j \geq 0.$$

**Proof of Theorem 10.2.** Let $x \in \ker T_{u_0}$. Clearly,

$$\Gamma\Phi xv = W^* \left( t_0 u_0 x \bigcirc \Phi(1) \right)^t \in H^2_+(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2}).$$

It follows that $\|\Gamma\Phi xv\|_2 = t_0\|xv\|_2$ which proves that

$$s_j(\Gamma\Phi) = t_0, \quad 0 \leq j \leq k_0 - 1. \quad (10.1)$$

We can now proceed by induction on $d$. Clearly, the result holds for $d = 1$. It is also obvious that if the theorem holds for $\Gamma\Phi(1)$, then by Theorem 10.1

$$t'_j \leq s_j(\Gamma\Phi), \quad k_0 \leq j \leq d - 1,$$

which together with (10.1) proves the theorem. □

**Proof of Theorem 10.1.** Clearly, it is sufficient to prove the following fact. Let $\mathcal{L}$ be a subspace of $H^2(\mathbb{C}^{m_1-1}) \oplus L^2(\mathbb{C}^{m_2})$ such that $\|\Gamma\Phi(1)\xi\|_2 \geq s\|\xi\|_2$ for every $\xi \in \mathcal{L}$, where $0 < s \leq t_0$, then there exists a subspace $\mathcal{M}$ of $H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2})$ such that $\dim \mathcal{M} \geq \dim \mathcal{L} + k_0$ and $\|\Gamma\rho\|_2 \geq s\|\rho\|_2$ for every $\rho \in \mathcal{M}$.

Let $\xi_i, 1 \leq i \leq N$, be a basis in $\mathcal{L}$. Put $\eta_i = \Gamma\Phi(1)\xi_i$. By Lemma 6.2 there exist scalar functions $\chi_i$ in $H^2$ such that $W^* \begin{pmatrix} \chi_i \\ \eta_i \end{pmatrix} \in H^2_-(\mathbb{C}^{m_1}) \oplus L^2(\mathbb{C}^{m_2})$. We define the functions $\xi_i^\# \in H^2(\mathbb{C}^{n_1}) \oplus L^2(\mathbb{C}^{n_2})$ by

$$\xi_i^\# = A^t\xi_i + q_i v,$$
 APPROXIMATION BY ANALYTIC MATRIX FUNCTIONS. THE FOUR BLOCK PROBLEM  33

where \( q_i \) is a scalar function in \( H^2 \) satisfying

\[
\mathbb{P}_+(t_0u_0q_i + t_0u_0v^*A^i\xi_i) = \chi_i
\]

(see the proof of Theorem 5.3).

We can now define \( \mathcal{M} \) by

\[
\mathcal{M} = \text{span}\{\xi_i^\# + xv : 1 \leq i \leq N, \, x \in \text{Ker} T_{u_0}\}.
\]

Let us show that \( \dim \mathcal{M} = N + k_0 \). Since \( \dim \text{Ker} T_{u_0} = k_0 \), it is sufficient to prove that if \( xv + \sum_{i=1}^N c_i\xi_i^\# \neq \emptyset \), then \( x = \emptyset \) and \( c_i = 0, \, 1 \leq i \leq N \). This follows immediately from (9.3).

To complete the proof it remains to show that \( \|\Gamma_\Phi \rho\|_2 \geq s\|\rho\|_2 \) for \( \rho = xv + \sum_{i=1}^r c_i\xi_i^\# \). Let \( \xi = \sum_{i=1}^r c_i\xi_i, \, \eta = \Gamma_\Phi(1)\xi, \, q = \sum_{i=1}^r c_iq_i, \) and \( \xi_i^\# = \sum_{i=1}^r c_i\xi_i^\# \).

We have

\[
W^* \left( \begin{array}{cc} t_0u_0 & \mathbb{0} \\ \mathbb{0} & \Phi(1) \end{array} \right) \rho = W^* \left( \begin{array}{cc} t_0u_0 & \mathbb{0} \\ \mathbb{0} & \Phi(1) \end{array} \right) (xv +qv + A^i\xi)
\]

\[
= W^* \left( \begin{array}{cc} t_0u_0 & \mathbb{0} \\ \mathbb{0} & \Phi(1) \end{array} \right) (x + q + v^*A^i\xi)
\]

\[
= W^* \left( \begin{array}{cc} t_0u_0x + t_0u_0q + t_0u_0v^*A^i\xi \\ \Phi(1)\xi \end{array} \right).
\]

It follows (see the proof of Theorem 5.3) that

\[
\Gamma_\Phi \rho = W^* \left( \begin{array}{cc} t_0u_0x + t_0u_0q + t_0u_0v^*A^i\xi \\ \Gamma_\Phi(1)\xi \end{array} \right).
\]

Therefore

\[
\|\Gamma_\Phi \rho\|_2^2 = |t_0|^2\|x + q + v^*A^i\xi\|_2^2 + \|\eta\|_2^2,
\]

We have

\[
\|\rho\|_2^2 = \|V^*\rho\|_2^2 = \|x + q + v^*A^i\xi\|_2^2 + \|\xi\|_2^2.
\]

Since \( s \leq t_0 \) and \( \|\eta\|_2 \geq s\|\xi\|_2 \), it follows that \( \|\Gamma_\Phi \rho\|_2^2 \geq s^2\|\rho\|_2^2 \). ■

Theorem [0.1] certainly applies to the case of Nehari’s problem. Recall that a matrix function \( \Phi \) is called very badly approximable (see [PY]) if the zero function is a superoptimal approximant of \( \Phi \).

Recall that under the condition \( \|H_\Phi\|_e < \|H_\Phi\| \) the function \( \Phi \) admits a factorization

\[
\Phi = W^* \left( \begin{array}{cc} t_0u_0 & \mathbb{0} \\ \mathbb{0} & \Phi(1) \end{array} \right) V^*,
\]

(10.2)

where \( V \) and \( W \) are unitary matrix functions of the form

\[
V = \left( \begin{array}{c} v \\ \mathbb{V}_e \end{array} \right), \quad W = \left( \begin{array}{c} w \\ \mathbb{W}_e \end{array} \right)^t,
\]
and $u_0$ is a unimodular function such that $k_0 \overset{\text{def}}{=} \dim \ker T_{u_0} > 0$.

The following result is certainly a partial case of Theorem 10.1.

**Theorem 10.3.** Let $\Phi$ be a very badly approximable matrix function on $\mathbb{T}$ such that $\|H_\phi\|_e$ is less that the smallest nonzero superoptimal singular value of Nehari’s problem. Then

$$s_j(H_\Phi^{(1)}) \leq s_{j+k_0}(H_\Phi), \quad j \in \mathbb{Z}_+,$$

where $\Phi^{(1)}$ and $k_0$ are given by the factorization (10.2).
