Abstract

Virgibacillus senegalensis SK-1T (= CSUR P1101 = DSM 28585) is the type strain of V. senegalensis sp. nov. It is an aerobic, Gram positive, moderately halophilic, motile bipolar flagellum isolated from a healthy Senegalese man. Here we describe the genomic and phenotypic characteristics of this isolate. The 3 755 098 bp long genome (one chromosome, no plasmid) exhibits a G + C content of 42.9% and contains 3738 protein-coding and 95 RNA genes.

Introduction

The concept of microbial culturomics is based on the variation of physicochemical parameters of the culture conditions so as to express the maximum of microbial diversity. It is based on rapid methods for identification, such as matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF) and 16S rRNA amplification and sequencing for unidentified colonies. This concept considerably enriches the gut microbiota repertoire, including new species not previously isolated from humans [1,2].

This isolation was part of a culturomics study we undertook using high-salt-containing culture conditions to grow halophilic bacteria from human stool [1].

The typical parameters used to define bacterial species comprise 16S rRNA sequencing and phylogeny, G + C content genomic diversity and DNA-DNA hybridization (DDH). However, some limitations have been noted [3–6]. By using the availability of data in genomics through the development of new tools for sequencing DNA, we introduced a new taxonomic method for the description of new bacterial species. This concept, which we named taxonogenomics, includes their genomic features [7] and proteomic information obtained by MALDI-TOF analysis [8–17].

The genus Virgibacillus was first proposed by Heyndrickx in 1998 with the transfer of Bacillus pantothenticus to Virgibacillus pantothenticus [18]. To date, there are more than 25 recognized species [19]. These bacteria are positive, Gram-variable rods which are ellipsoidal to oval endospores and have DNA G + C content ranging from 36% to 43% [20]. These species were isolated from sediments of a salt lake [20–23], fermented seafood in traditional salt [24], a permafrost core collected from the Canadian high Arctic [25], a navy solar salt marsh [26,27], soil [28], seawater [29], field soil, a dairy product [30], residual wash water produced during processing wastewater, Spanish-style green table olives [31], saline sample of mud, salt...
crust [32] and Thai fermented fish [33]. Here we present a brief classification and a set of features for strain SK-1T \( (= \) CSUR P1101 = DSM 28585), with a description of the complete genome sequence and annotation. We named this new isolate *Virgibacillus senegalensis*.

## Materials and Methods

### Sample and culture condition

The stool sample was collected from a healthy male Senegalese volunteer patient living in N'Diop, a rural village in the Guinean–Sudanian zone in Senegal. After the patient provided signed informed consent, the sample was collected in a sterile pot and transported to our laboratory. The study and the assent procedure were approved by the National Ethics Committee of Senegal and by the ethics committees of the Institut Fédératif de Recherche 48, Faculty of Medicine, Marseille, France (agreement 09-022). The salt concentration of the stool specimen was determined by a digital refractometer (Fisher Scientific, Illkirch, France) and the pH with a pH meter (Cyberscan 510PH; Eutech Instruments, Singapore).

Strain SK-1T was isolated in February 2014 by aerobic culture on a homemade culture medium consisting of a Columbia agar culture medium (Sigma-Aldrich, Saint-Quentin Fallavier, France) modified by adding (per liter): MgCl₂ 6H₂O, 5 g; MgSO₄ 7H₂O, 5 g; KCl, 2 g; CaCl₂ 2H₂O, 1 g; NaBr, 0.5 g; NaHCO₃, 0.5 g; glucose, 2 g; and 100 g/L of NaCl. The pH was adjusted to 7.5 with 10 M NaOH before autoclaving.

### MALDI-TOF identification

An isolated colony was deposited in duplicate on a MALDI-TOF target to be analysed. A matrix of 1.5 \( \mu \)L (saturated solution of α-cyano-4-hydroxycinnamic acid diluted in 500 \( \mu \)L acetonitrile, 250 \( \mu \)L of acid tri-fluoro-acetic to 10%, and 250 \( \mu \)L of HPLC water) was used on each spot. This solution enables ionization and desorption of the homogeneous biological sample with which it crystallizes. The analysis was performed by a Microflex (Bruker Daltonics, Leipzig, Germany) device, and protein spectra were compared with those of the hospital database. A score was assigned indicating the reliability of the identification of the bacteria; above 1.9 was considered proper identification. Conversely, if the bacterium was not referenced in the database, sequencing the 16S rRNA was used to achieve the correct identification [34].

### Identification by sequencing of 16S rRNA

Colonies not identified by the MALDI-TOF after three tests were suspended in 200 \( \mu \)L of distilled water for DNA extraction by EZ1 DNA Tissue Kit (Qiagen, Venlo, The Netherlands). The amplification of the 16S rRNA was performed by standard PCR in a thermocycler using the universal primer pair FD1 and rp2 according to the following amplification program: activation of the polymerase (95°C for 5 minutes), followed by 40 cycles (95°C 30 seconds, 52°C 45 seconds, 72°C 2 minutes), followed by 5 minutes at 72°C. The DNA amplified by this reaction was revealed by electrophoresis on 1.5% agarose gel. Once validated, the PCR product was purified and sequenced using the Big Dye Terminator Sequencing Kit using the internal primers 536F, 536R, 800F, 800R, 1050F and 1050R, as previously described [2].

### Phylogenetic analysis

Phylogenetic analysis based on 16S rRNA of our isolates was performed to identify its phylogenetic affiliations with other near isolates, including other members of the genus *Virgibacillus*. MEGA 6 software (http://www.megasoftware.net/mega.php) allowed us to construct a phylogenetic tree. Sequence alignment of the different species was performed using Clustal W (http://www.clustal.org/clustalw2/), and the evolutionary distance was calculated with the Kimura two-parameter model [35].

### Biochemical, atmospheric and antimicrobial susceptibility tests

Biochemical tests were performed using the commercially available Api ZYM (bioMérieux, Marcy l’Étoile, France), API 50CH (bioMérieux) and 20 NE (bioMérieux) strips. The incubation time was 48 hours for the API 50CH and 20 NE, and 4 hours for Api ZYM. Growth of strain SK-1T was tested in aerobic atmosphere, in the presence of 5% CO₂ and also in anaerobic and microaerophilic atmospheres, created using AnaeroGen (Atmosphere Generation Systems, Dardilly, France). Antibiotic susceptibility was determined by Muller- Hinton agar in a petri dish (bioMérieux). The following antibiotics were tested: doxycycline, rifampicin, vancomycin, nitrofurantoin, amoxicillin, erythromycin, ampicillin, ceftriaxone, ciprofloxacin, gentamicin, penicillin, trimethoprim/sulfamethoxazole, imipenem and metronidazole.

### Genome Sequencing Information

#### Genomic DNA preparation

We cultured our strain in the homemade culture. After 48 hours, bacteria grown on four petri dishes were resuspended in sterile water and centrifuged at 4°C at 2000 × g for 20 minutes. Cell pellets were resuspended in 1 mL Tris/EDTA/NaCl (10 mM Tris/HCl (pH7.0), 10 mM EDTA (pH8.0) and 300 mM...
Genome sequencing and assembly

Genomic DNA of *Virgibacillus senegalensis* was sequenced on the MiSeq Technology (Illumina, San Diego, CA, USA) with the mate pair strategy. The gDNA was bar coded in order to be mixed with 11 other projects with the Nextera Mate Pair sample prep kit (Illumina). gDNA was quantified by a Qubit assay with the high sensitivity kit (Life Technologies) to 155 ng/μL. The mate pair library was prepared with 1 μg of genomic DNA using the Nextera mate pair Illumina guide. The genomic DNA sample was simultaneously fragmented and tagged with a mate pair junction adapter. The pattern of the fragmentation was validated on an Agilent 2100 BioAnalyzer (Agilent Technologies, Santa Clara, CA, USA) with a DNA 7500 lab chip. The DNA sample was simultaneously fragmented and tagged with a Nextera Mate pair junction adapter. The pattern of the fragmentation was validated on an Agilent 2100 BioAnalyzer (Agilent Technologies, Santa Clara, CA, USA) with a DNA 7500 lab chip. The DNA fragments ranged in size from 1 to 11 kb, with an optimal size at 4.008 kb. No size selection was performed, and 388.3 ng of tagmented fragments were circularized. The circularized DNA was mechanically sheared to small fragments with an optimal at 634 bp on the Covaris device S2 in microtubes (Covaris, Woburn, MA, USA). The library profile was visualized on a High Sensitivity Bioanalyzer LabChip (Agilent Technologies), and the final concentration library was measured at 35.59 nmol/L. The libraries were normalized to 2 nM and pooled. After a denaturation step and dilution at 15 μM, the pool of libraries was loaded onto the reagent cartridge and then onto the instrument along with the read cell. Automated cluster generation and sequencing run were performed in a single 39-hour run in a 2 × 251 bp. Total information of 10.6 Gb was obtained from a 1326K/mm² cluster density with a cluster passing quality control filters of 99.1% (24 492 260 clusters). Within this run, the index representation for *Virgibacillus senegalensis* was determined to be 7.06%. The 1,481,197 paired reads were filtered according to the read qualities. These reads were trimmed, then assembled using CLC genomicsWB4 software.

Genome annotation and comparison

Open reading frames (ORFs) were predicted using Prodigal [36] with default parameters, but the predicted ORFs were excluded if they spanned a sequencing gap region. The predicted bacterial protein sequences were searched against the GenBank database [37] and the Clusters of Orthologous Groups (COGs) database using BLASTP. The tRNAscanSE tool [38] was used to find tRNA genes, whereas ribosomal RNAs were found using RNAmer [39] and BLASTn against the GenBank database. Lipoprotein signal peptides and the number of transmembrane helices were predicted using SignalP [40] and TMHMM [41], respectively. ORFans were identified if their BLAST E value was lower than 1e⁻⁰³ for alignment length greater than 80 aa. If alignment lengths were smaller than 80 aa, we used an E-value of 1e⁻⁵⁵. Such parameter thresholds have already been used in previous works to define ORFans. Artemis [42] was used for data management and DNA Plotter [43] for visualization of genomic features. Maui's alignment tool (version 2.3.1) was used for multiple genomic sequence alignment [44]. To estimate the mean level of nucleotide sequence similarity at the genome level, we used an in-lab pipeline software named Marseille Average Genomic Identity (MAGI) to calculate the average genomic identity of gene sequences (AGIOS) among compared genomes [45]. Briefly, this software combines the Proteinortho software [45] for detecting orthologous proteins in pairwise genomic comparisons, then retrieves the corresponding genes and determines the mean percentage of nucleotide sequence identity among orthologous ORFs using the Needleman-Wunsch global alignment algorithm. Genomes from the genus *Virgibacillus* and closely related genera were used for the calculation of AGIOS values. Here we compared the genome sequences of *Virgibacillus senegalensis* strain SK-1T (GenBank accession number PRJEB1962) with those of *Virgibacillus kkeksis* strain YIM lknny9 (NR_042744.1), *Virgibacillus olibus* strain YIM 93624 (NR_109613.1), *Aquibacillus salifodinae* WSY08-1 (AB859945.1), *Virgibacillus halodenitrificans* DSM 10037 (AY543169), *Thalassobacillus devorans* devorans MSP14 (JX518269.1), *Halobacillus dabanensis* HD 02 (HG931924.2), *Halobacillus kurashimensis* DSM 18393 (AB195680.1), *Thalassobacillus devorans* strain XJS-L7-8 (GQ903447.1), *Bacillaceae bacterium EFN-4* (EU817569.1), *Virgibacillus marismortui* strain M3-23 (GQ282501.1), *Halobacillus salinus* strain GSP59 (AY505517.1), *Virgibacillus alimentarius* J18 (GU202420), *Pseudomonas aeruginosa* PAO1 (NR_074828.1) and *Virgibacillus massiliensis* (CCDP010000001).

Results

Phenotypic description

Strain SK-1T was isolated in February 2014 (Table 1) by aerobic culture on a homemade culture medium at 37°C after 48 hours. No significant MALDI-TOF result for the strain SK-1T against...
our MALDI-TOF database was obtained, suggesting that our isolate was not a previously known species. We added the specter of SK-1T strain to our database (Fig. 1). The gel view allowed us to observe the spectral differences with other members of *Virgibacillus* genus (Fig. 2). PCR-based identification of the 16S rRNA of our new isolate (GenBank accession number LK021111) yielded 96.3% 16S rRNA sequence similarity with the reference *Virgibacillus kakensi* (GenBank accession number NR042744), the phylogenetically closest validated *Virgibacillus* species (Fig. 3).

After growth for 24 hours on our homemade culture medium at 37°C, the surface colonies were circular, greyish, shiny and smooth, with a diameter of 1 to 2 mm. *V. senegalensis* is Gram positive (Fig. 4).

Growth was observed at temperatures ranging from 25 to 40°C, with an optimum at 37°C. The growth required a salinity ranging from 5 to 200 g/L of NaCl (optimum at 75 g/L). The optimum pH for growth was 7.5 (pH range 5 to 9). Growth of the strain SK-1T was tested in an aerobic atmosphere, in the presence of 5% CO2 and also in anaerobic and microaerophilic atmospheres created using AnaeroGen (Atmosphere Generation Systems), respectively. The strain was strictly aerobic and also grew in the presence of 5% CO2 but did not grow in an anaerobic atmosphere. The size and ultrastructure of cells were determined by negative staining transmission electron microscopy 2 to 6 μm in length and 0.5 μm in diameter (Fig. 5). Using the commercially available Api ZYM, Api 20NE (bioMérieux), to characterize the biochemical *V. senegalensis* strain SK-1T, positive reactions were observed for urease, β-glucosidase, and

protease, β-galactosidase and arginine hydrolase. All other tested reactions were negative, notably nitrate reduction alkaline phosphatase and N-acetyl-β-D-glucosaminidase. The stain was also catalase and oxidase negative. Substrate oxidation and assimilation were examined with an API 50CH strip (bio-Mérieux) at 37°C. Negative reactions were obtained for D-mannose, D-lactose, L-arabinose, D-galactose, D-ribose, D-sucrose, D-fructose, D-glucose, D-mannitol and D-maltose. Phenotypic characteristics were compared to those of the most closely related species (Table 2).

Finally, antimicrobial susceptibility testing demonstrate that the strain SK-1T was susceptible to doxycycline, rifampicin, vancomycin, nitrofurantoin, amoxicillin, erythromycin, ampicillin, ceftriaxone, ciprofloxacin, gentamicin, penicillin, trimethoprim/sulfamethoxazole and imipenem, but resistant to metronidazole.

**Genome Sequencing Information**

**Genome properties**

The draft genome of *V. senegalensis* consists of nine scaffolds with 59 contigs.

The genome is, 755,098 bp long with a 42.9% G+C content (Table 3, Fig. 6). Of the 3833 predicted genes, 3738 (96.46%) were protein-coding genes and 95 (2.44%) were RNAs (14 genes were 5S rRNA, five genes 16S rRNA, seven genes 23S rRNA, 69 genes tRNA). A total of 2773 genes (62.82%) were assigned a putative function, 2427 genes (65.43%) were assigned to COGs and 155 genes (4.04%) contained peptide signals, whereas 980 (25.56%) genes had transmembrane helices. A total of 245 genes were identified as ORFans (6.39%). The remaining genes were annotated as hypothetical proteins. The properties and statistics of the genome are summarized in

![FIG. 2. Gel view comparing *Virgibacillus senegalensis* sp. nov. SK-1T to members of family *Virgibacillus* and *Oceanobacillus*. Left y-axis displays running spectrum number originating from subsequent spectra loading. Peak intensity is expressed by greyscale scheme code. Color bar and right y-axis indicate relation between color peak; peak intensity expressed in arbitrary units. Displayed species are indicated at left.](image-url)
Tables 3 and 4. The distribution of genes into COGs functional categories is presented in Table 5.

**Genome comparison**

The draft genome of *V. senegalensis* SK-1T is smaller than those of *Halobacillus kuroshimensis* DSM 18393, *Virgibacillus halodenitri* cans DSM10037, *Thalassobacillus devorans* XJSL7-8, *Halobacillus dabanensis* HD 02 and *Pseudomonas aeruginosa* PAO1 (3.85, 3.92, 3.94, 4.1 and 6.26 Mb, respectively) but larger than that of *Virgibacillus albus* strain YIM 93624 (3.05 Mb). The G + C content of *V. senegalensis* SK-1T is smaller than those of *Halobacillus kuroshimensis* DSM 18393 and *Pseudomonas aeruginosa* PAO1 (47.0% and 66.60%, respectively) and larger than those of *Virgibacillus albus* strain YIM 93624 (47.0%). Protein-coding genes of *V. senegalensis* SK-1T were smaller than those of *Virgibacillus halodenitri* cans DSM10037, *Thalassobacillus devorans* XJSL7-8, *Halobacillus kuroshimensis* DSM 18393, *Halobacillus dabanensis* HD 02 and *Pseudomonas aeruginosa* PAO1 (3748, 3752, 3832, 3835 and 5572 Mb, respectively) but larger than those of *Virgibacillus albus* strain YIM 93624 (2889 Mb). Total gene content of *V. senegalensis* SK-1T (3883) is smaller than those of *Halobacillus kuroshimensis* DSM 18393, *Halobacillus dabanensis* HD 02 and *Pseudomonas aeruginosa* PAO1 (3915, 4011, and 5697 respectively) but larger than those of *Virgibacillus halodenitri* cans DSM10037 and *Virgibacillus albus* strain YIM 93624 (3022, respectively).

**FIG. 3.** Phylogenetic tree highlighting position of *Virgibacillus senegalensis* strain SK-1T (= CSUR P1101 = DSM 28585) relative to other type strains of *Virgibacillus albus* strain YIM 93624 (NR_109613.1), *Virgibacillus kekensis* strain YIM kkny16 (NR_042744.1), *Virgibacillus alimentarius* strain J18 (NR_108710.1), *Virgibacillus marismortui* strain M3-23 (GQ282501.1), *Virgibacillus necropolis* strain LMG 19488 (NR_025472.1), *Virgibacillus carmonensis* strain LMG 20964 (NR_025481.1), *Virgibacillus subterraneus* strain H57B72 (FJ746573.1), *Virgibacillus zhanjiangensis* strain JSM 079157 (FJ425904.1), *Virgibacillus litoralis* strain JSM 089168 (FJ425909.1), *Virgibacillus dokdonensis* strain DSW-10 (NR_043206.1), *Virgibacillus siemensis* strain M3-4 (AB365482.1), *Virgibacillus salarius* strain SA-Vb1 (NR_041270.1), *Virgibacillus halophilus* strain SB73C (NR_041358.1), *Virgibacillus natechei* strain FarD (NR_132721.1), *Virgibacillus chiguensis* strain NTU-101 (NR_040861.1), *Virgibacillus dokdonensis* strain DSW-10 (NR_043206.1), *Virgibacillus campisalis* strain IDS-20 (GUS8225.1), *Virgibacillus pantothenticus* strain NBRC 102447 (AB681789.1), *Virgibacillus halodenitri* cans strain NBRC 102361 (AB681753.1), *Virgibacillus byunsanensis* strain ISL-24 (FJ357159.1), *Virgibacillus massiliensis* strain Vm-5 (HG931931.1) and *Paenibacillus polymyxa* strain KCTC3717 (AY359637.1). GenBank accession numbers are indicated in parentheses. Sequences were aligned using Clustal W (http://www.clustal.org/clustal2/), and phylogenetic inferences were obtained using maximum-likelihood method within MEGA 6 (http://www.megasoftware.net/omega.php). *Paenibacillus polymyxa* was used as outgroup. Scale bar = 0.005% nucleotide sequence divergence.
Among species with standing in nomenclature, AGIOS values ranged from 66.41% between *V. senegalensis* SK-1T and *Halobacillus kuroshimensis* DSM 18393 to 73.39% between *Halobacillus dabanensis* HD 02 and *Halobacillus kuroshimensis* DSM 18393. To evaluate the genomic similarity among studied strains, in addition to AGIOS [7], which was designed to be independent from DDH, we determined a digital DDH that exhibited a high correlation with DDH [46,47]. Digital DDH ranged from 18.4% to 27.2% between the different species tested (Table 6, Fig. 7).

Conclusion

On the basis of phenotypic, genomic and phylogenetic analyses, we formally propose the creation of Virgibacillus senegalensis sp. nov., represented here by the SK-1T strain. The strain was isolated from a stool sample of a Senegalese healthy individual.

### TABLE 3. Nucleotide content and gene count levels of genome

| Attribute                        | Value  | % of total |
|----------------------------------|--------|------------|
| Size (bp)                        | 3,755,098 | 100        |
| G + C content (%)                | 1,610,937 | 42.9       |
| Coding region (bp)               | 1,129,675 | 31.34      |
| Total genes                      | 3,883   | 100        |
| RNA genes                        | 95      | 2.44       |
| Protein-coding genes             | 3,738   | 98.46      |
| Genes with function prediction   | 2,773   | 62.82      |
| Genes assigned to COGs           | 2,421   | 65.43      |
| Genes with transmembrane helices | 980     | 25.56      |

COGs, Clusters of Orthologous Groups database.

*Total is based on total number of protein-coding genes in annotated genome.

**FIG. 6.** Graphical circular map of *Virgibacillus senegalensis* sp. nov. SK-1T chromosome. From outside in, outer two circles show open reading frames oriented in forward (colored by COGs categories) and reverse (colored by COGs categories) directions, respectively. Third circle marks tRNA genes (green). Fourth circle shows percentage G + C content plot. Innermost circle shows GC skew, purple indicating negative values and olive positive values. COGs, Clusters of Orthologous Groups database.
**TABLE 5.** Numbers of orthologous proteins shared between genomes (upper right), average percentage similarity of nucleotides corresponding to orthologous proteins shared between genomes (lower left) and numbers of proteins per genome (bold)

*Comparison made using GGDC formula 2 (DDH estimates based on identities/HSP length). Confidence intervals indicate inherent uncertainty in estimating DDH values from intergenomic distances based on models derived from empirical test data sets (which are always limited in size). These results are in accordance with 16S rRNA (Fig. 1) and phylogenomic analyses as well as GGDC results. DDH, DNA-DNA hybridization; HSP, high-scoring pair.

**Taxonomic and nomenclatural proposals**

**Description of *Virgibacillus senegalensis* sp. nov.**

*Virgibacillus senegalensis* (se.ne.ga.len’sis. L. masc. adj. senegalensis of Senegalia, the Roman name for Senegal, where the type strain was isolated). Growth occurred between 15°C and 45°C on a homemade culture medium (described above), with optimal growth observed at 37°C in an aerobic atmosphere. Strain SK-1T required a salinity ranging from 5 to 200 g/L of NaCl (optimum at 100 g/L). The optimum pH for growth was 7.5 (range, 5 to 9). The strain SK-1T was strictly aerobic and also grew in the presence of 5% CO₂, but no growth was observed under anaerobic and microaerophilic conditions. The colonies of the strain SK-1T were circular, greyish, shiny and smooth, with a diameter of 2 to 6 mm. Cells stained Gram positive. They were motile by polar flagella, spore forming (2 to 6 μm in length and 0.5 μm in diameter) and generally occurred individually or in pairs. Strain SK-1T is catalase and oxidase negative. Using API 50 CH and API20 NE (bioMérieux), strain SK-1T was positive.
for reduction of nitrates but negative for phosphatase alkaline activity, α-galactosidase, αN-acetyl-α-glucosaminidase and urease. Strain SK-1T was negative for ribose, L-arabinose and D-lactose assimilation and positive for D-glucose, D-fructose, D-mannose, D-mannitol, D-maltose and D-sucrose. The strain SK-1T was susceptible to doxycycline, rifampicin, vancomycin, nitrofurantoïn, amoxicillin, erythromycin, ampicillin, ceftriaxone, ciprofloxacin, gentamicin, penicillin, trimethoprim/sulfamethoxazole and imipenem, but resistant to metronidazole.

The percentage of G + C content of the genome is 42.9%. The 16S rRNA and genome sequences are deposited in GenBank under accession numbers LK021111. The habitat of the microorganism is the human digestive tract. The type strain SK-1T (= CSUR P1101, = DSM 28585) was isolated from a stool specimen of a healthy Senegalese man.
