INTRODUCTION

Malaria is a major infectious disease in the Greater Mekong Subregion (GMS) in Asia. Although there has been a considerable decrease in the incidence of malaria in China [1], Yunnan Province still has the highest transmission area of vivax malaria in China, particularly in the southern border areas adjacent to Myanmar. Plasmodium vivax is also the most widely distributed species of all 5 human malaria parasites in Southeast Asia and accounts for 65% of malaria cases in Asia and South America [2]. More attention is being focused on malaria today than any time since the world’s last efforts to achieve eradication over 40 years ago. The global community is now discussing strategies aimed at dramatically reducing malarial disease burden and the eventual eradication of all types of malaria everywhere. As a consequence, P. vivax, which has long been neglected and mistakenly considered benign, is now entering into the strategic debates taking place on malaria epidemiology and control, drug resistance, pathogenesis, and vaccines. Thus, contrary to the past, the malaria research community is becoming more aware and concerned about the widespread spectrum of illness and death caused by up to a couple of hundred million cases of vivax malaria each year [3].

Taking account of the facts above, availability of P. vivax malaria vaccine is highly desirable. Advanced studies on genetic diversity of the most variable domain of vaccine candidate P. vivax merozoite surface proteins (PvMSPs) in field isolates of different countries have been carried on and demonstrated that the diversity of MSPs in P. vivax is presumed be associated to parasite immune evasion and be important for the rationale
of malaria vaccine designs [4, 5]. Since the 42 kDa fragment of
Plasmodium merozoite surface protein-1 (PvMSP1) contains
known B- and T-cell cell epitopes, a PvMSP142 vaccine antigen
may be capable of conferring protection mediated by provid-
ing antigen-specific T-cell help for B-cells and antibody pro-
duction [6]. Several previous studies have reported the pres-
ence of acquired antibodies against the C-terminus part of the
protein called PvMSP119 or PvMSP142 antigens among individ-
uals during natural P. vivax infections [7, 8]. Immunological
studies performed on animal models have also proved that the
PvMSP119 or PvMSP142 is one of the promising vaccine candi-
dates against asexual stages of the malaria [9]. Although genet-
ic polymorphisms in the central repeat region of PvMSP1 has
been investigated among other countries in Southeast Asia on
P. vivax isolates [10], the data is not available for the C-termi-
nus region of this antigen from southern border areas adjacent
to Myanmar and the inland cases in China.

The present study aimed to identify the genetic diversity and
haplotypes of the gene fragment coding PvMSP142 in P. vivax
isolates of malaria cases in China-Myanmar border (CMB) ar-
eas and Yunnan, Zhejiang, and Anhui province of inland of
China. Moreover, the natural selection of the gene fragment
coding PvMSP142 was tested in 4 P. vivax populations from
CMB areas and inland of China.

MATERIALS AND METHODS

Ethics statement

This study was conducted according to the principles ex-
pressed in the Declaration of Helsinki. Blood collections were
made with full informed consent of the patients and following
institutional ethical guidelines that were reviewed and ap-
proved by the ethics committee at National Institute of Para-
sitic Diseases, Chinese Center for Disease Control and Preven-
tion.

Blood samples, DNA extraction, and purification

Blood samples were obtained from 77 symptomatic and
microscopically confirmed P. vivax malaria patients in China
during 2009 to 2012. These examined samples included 59
imported cases of CMB areas based on their traveling history,
including 14, 19, 17, and 9 cases each year from 2009 to 2012,
respectively, and additional 18 patients from inland China.
Among the 18 samples from inland China, 6 of them were
from Anhui province collected in 2009, 6 from Zhejiang prov-
ince collected in 2009 and 6 from Yunnan province collected
in 2010 (Fig. 1). Annual parasite incidence (API) for Anhui,
Zhejiang and Yunnan province was 0.0210, 0.0352, and 0.2186
per 10,000 person-years in 2015 [11]. Because the transmission
of malaria had been controlled in a very low level in local Chi-
na, only limited sporadic cases of malaria inland were collect-
ed here. These samples collected from different villages in
Yunnan province treated as the inland malaria cases from
these febrile patients haven’t been abroad within 1 month. All
the patients’ P. vivax infection were diagnosed by microscopic
examination of thin and thick blood smears and further con-
firmed by nested PCR as described previously [12].

Genomic DNA was isolated from 200 μl of venous blood
which collected in a sterile heparinized tube from the patients
who were found positive for P. vivax. Approximately 100 μl of
blood each patient was used and added 100 μl PBS to get the
final volume of 200 μl. Then, DNA was extracted from the
whole blood by using the QIAamp DNA mini kit (QIAGEN,
Shanghai, China), according to the manufacturer’s instructions.
The purified DNA was dissolved in 150 μl TE buffer (10 mM
Tris-HCl, 1 mM EDTA; pH 8.0) and stored at -20°C until use.

PCR amplification and analysis of P. vivax field isolates

The P. vivax fragment (comprising PvMSP142 kDa amino ac-
ids) of PvMSP142 was amplified by polymerase chain reaction (PCR). In this study, the specific primer was designed according to the P. vivax MSP1 complete gene sequence of PlasmoDB (PVX_099980) [13]. The primers are: Pv1SF (5’-AGAAG AAAAC GTAGC AGCAA-3’) and Pv1SR (5’-AAGCC CAGTT CAGTT CAGAA CTCA-3’). PCR reaction volumes were 50 μl. The cycling parameters for PCR amplification was performed under the following conditions: initial denaturation 5 min at 94˚C, 35 cycles of denaturation at 94˚C for 30 sec, annealing at 55˚C for 30 sec, and extension at 72˚C for 1 min 30 sec, followed by a final extension at 72˚C for 5 min. PCR mixture reagents contained 1 μl of DNA, 0.5 units of ExTaq or LATaq DNA polymerase (Takara, Shiga, Japan), 0.2 mM of each primer, 0.1 mM dNTPs in a 25 μl of reaction mix with 1.5 mM MgCl2. The PCR products were examined by electrophoresis in a 1% agarose gel, visualized with an ultraviolet trans-illuminator and purified with PCR purification kits (Qiagen). Then, the purified PCR products were sequenced using the forward primers on an ABI PRISM 3700 DNA capillary sequencer, by BGI Company (Shenzhen, Guangdong, China). All unique mutations were carefully checked, and ambiguous bases were confirmed by resequencing. We also carried out a BLAST search on PlasmoDB Genebank Database of P. vivax to compare these successfully sequenced isolates with those previously identified from China and the Asia-pacific subregion. Accurate alignment of the sequences was performed by in ClustalX version 2.0 [14]. The new sequences were deposited in GenBank with accession nos. JX490129-JX490156, JX993754, and JX993755.

**Nucleotide diversity and natural selection test of P. vivax field isolates**

Nucleotide and amino acid sequences were aligned using Clustal W in MEGA 5.0 [15]. First, nucleotide diversity (π) was computed in 100 bp sliding window and 25 bp step size using DnaSP v.5.0 [16]. Then, to detect natural selection acting on these coding sequences, the rates of non-synonymous (dN) to synonymous (dS) substitution (dN/dS) was calculated with DnaSP v.5.0. If the amino acid change is deleterious, purifying selection, then dN/dS < 1; only when the amino acid change offers a selective advantage, the dN/dS is > 1. In addition, Tajima’s D was used to test neutrality of this gene fragment in DnaSP v.5.0 [16,17]. A remarkable negative value of Tajima’s D reveals an excess of rare variants as expected under positive and negative selection or population size expansion. Whereas, a significant positive value demonstrates an excess of high-frequency variant as expected under balancing selection or under population structure. Finally, to describe the genetic similarities among PvMSP142 haplotypes, we constructed networks by the median joining method from 41 unique haplotypes on the basis of PvMSP142 sequences in Network 4.5 [18].

**Phylogenetic analysis of PvMSP1 from P. vivax field isolates**

The phylogenetic relationships were derived from the PvMSP142 sequences. In case of individuals that carried an identical sequence (it is possible that individuals from different locations shared the same sequence), only 1 sequence was included for the tree reconstruction. The reference sequences were chosen from GenBank. Then, partitioned Neighbor-Joining method was performed in MEGA 5.0 [15,19] to construct the phylogenetic tree (with Kimura-2 parameter distance, branch support with 1000 bootstrap replicates, and complete deletion of gaps). MSP142 fragment gene of P. cynomolgi strain Berok was set as the out group.

**RESULTS**

**Haplotype variations in P. vivax of different field isolates**

We successfully amplified and sequenced the gene encoding PvMSP142 fragment (1,209 bp, corresponding to amino acid positions 1350-1752 in PvMSP1) shown in Supplementary Fig. S1. Of 77 isolates from 4 geographic locations, 41 haplotypes were detected on the entire PvMSP142 fragment (Table 1). From these 41 haplotypes, 30 were new haplotypes. Only 1 single haplotype was detected among 6 isolates from Anhui, all these samples were collected from Bengbu city and 2 haplotypes from 6 isolates in Zhejiang province. In contrast, other 6 isolates from Yunnan province distributed in different villages are detected in 6 different haplotypes and 35 haplotypes are detected from 59 imported cases of CMB areas. Only 3 haplotypes were detected for PvMSP133 fragment in comparison with 38 haplotypes for PvMSP142 fragment in the all sequenced isolates. The consistent pattern was observed in the P. vivax populations from CMB areas and inland China (Table 1).

**Nucleotide diversity and natural selection of different PvMSP142 fragment from different P. vivax isolates**

The overall nucleotide diversity (π) of PvMSP142 for all of 77
isolates was 0.01901, and π values were 0.01803 and 0.01235 for the isolates from Yunnan and Zhejiang province of inland China, respectively, as well as π value was 0.01836 for the isolates from the CMB areas, with the peak on nucleotide positions from 476 to 525 bp (Fig. 2), which located at the C-terminal 33 kDa fragment within PvMSP1 gene (PvMSP133) (Supplementary Figs. S2, S3).

The rates of non-synonymous (dN) to synonymous (dS) substitution (dN/dS) of PvMSP142 for all of 77 isolates was 2.15354, and the rates of dN/dS were 6.10383, 7.39713, and 1.92699 for the isolates from Yunnan, Zhejiang province of inland China and CMB areas, respectively, suggesting a positive selection for PvMSP142 of *P. vivax* populations from inland China and CMB areas. The overall Tajima’s D value of PvMSP142 was 2.44824 (<0.05) for all of 77 isolates, and the Tajima’s D values were 0.23699, 1.37681, and 2.01030 for the isolates from the Yunnan, Zhejiang province of inland China and CMB areas, respectively, which also indicated balancing selection for PvMSP142 of *P. vivax* populations from CMB areas.

### Table 1. Haplotype diversity, nucleotide diversity, and natural selection of *Plasmodium vivax* MSP1a2

†Border areas: China-Myanmar border areas.

---

**Fig. 2.** Nucleotide diversity per site (π) at PvMSP142 from *P. vivax* isolates collected along the China-Myanmar border areas, local regions of Yunnan and Zhejiang provinces in inland China.

**Fig. 3.** The network of PvMSP142 from *P. vivax* isolates collected along the China-Myanmar border areas, local regions of Anhui, Yunnan, and Zhejiang provinces in China.
The network of 41 haplotypes from 77 isolates of PvMSP1$_{42}$ showed that most prevalent haplotypes originated from Myanmar followed by Yunnan and Zhejiang provinces of China. Moreover, the haplotypes in the studied P. vivax populations were highly diverse (35/59) in the Myanmar population, and in extremely case, all isolates from Yunnan showed independent haplotypes. In contrast, Zhejiang and Anhui population in inland China showed the low haplotype diversity. The haplotypes were consistent with the distribution of allele frequencies as shown (Table 1; Fig. 3).

**Nucleotide diversity and natural selection of different PvMSP1$_{33}$ and PvMSP1$_{19}$ fragments from different P. vivax isolates**

The overall nucleotide diversity ($\pi$) of PvMSP1$_{33}$ for all of 77 isolates was 0.02617, and $\pi$ values were 0.02467 and 0.01716 for the isolates from Yunnan and Zhejiang province of inland China, respectively, as well as $\pi$ value was 0.02523 for the isolates from the CMB areas (Table 1; Fig. 2). The overall nucleotide diversity ($\pi$) of PvMSP1$_{19}$ for all of 77 isolates was 0.00063, and $\pi$ values were 0.00098 and 0.00073 for the isolates from Yunnan province of inland China and the CMB areas, respectively (Table 1; Fig. 2).

The rates of $dN/dS$ for PvMSP1$_{33}$ were 6.02554, 7.44483, and 1.93351 for the isolates from Yunnan, Zhejiang province of inland China and CMB areas, respectively, suggesting the positive selection located at PvMSP1$_{33}$ fragment of P. vivax populations from inland China and CMB areas. Furthermore, the rate of $dN/dS$ for PvMSP1$_{19}$ was 1.68750 for the isolates from CMB areas.

Moreover, the overall Tajima’s D value of PvMSP1$_{33}$ was 2.57163 ($P < 0.05$) for all of 77 isolates, and the Tajima’s D values were 0.27447, 1.37681, and 2.11738 for the isolates from Yunnan, Zhejiang province of inland China and CMB areas, respectively, also suggesting a positive balancing selection of PvMSP1$_{33}$ in the CMB population (Tajima’s D = 2.11738, $P < 0.05$) (Table 1). However, Tajima’s D values were negative for PvMSP1$_{19}$ in the CMB areas (-0.73272) and Yunnan population (-0.93302), indicating the purifying selection (Table 1).

**Phylogenetic diversity of PvMSP1$_{42}$ from P. vivax of different field isolates**

The phylogenetic tree showed that all these isolates of P. vivax clinical patients from different regions such as Myanmar, Thailand, Singapore, Bangladesh, South Korea, India, Vietnam, and Indonesia having high prevalence (Fig. 4). What’s more, the P. vivax clinical samples showed distinct differences haplotypes among the isolates collected from different province in China.
or different villages in Yunnan province. The phylogenetic analysis revealed that newly identified haplotypes from China were clustered differently. The gene coding PvMSP142 from field isolates collected in Anhui province has only 1 haplotype and close to these isolates from Myanmar. Two different haplotypes of PvMSP142 were detected from Zhejiang isolates. One sequence coding PvMSP142 from Zhejiang province is close to these from Yunnan province and Myanmar, while another one also detected in Zhejiang isolates has been demonstrated to be close to isolates from Singapore and Thailand. All these genes coding PvMSP142 from Yunnan are from those patients who haven’t been abroad within 1 month.

**DISCUSSION**

The *P. vivax* parasite exhibits higher genetic diversity than *P. falciparum*, especially for the gene families associated with merozoite invasion or immune response modulation (e.g., the *msp3*, *vir*, and *msp7* gene families) [20-22]. The high genetic diversity and natural selection of *P. vivax* vaccine targets is common existed in isolates world-wide [23,24]. The PvMSP1 locus codes for a major asexual blood-stage antigen currently proposed as a malaria vaccine candidate antigen. Reports of extensive polymorphism of this protein from field isolates and clones from different geographical areas remain a major challenge. Numerous studies on the genetic diversity of PvMSP1 in *P. vivax* field isolates have been carried out in many different geographic areas [25,26]. However, there is no available data for PvMSP142 from southern border areas adjacent to Myanmar and the inland cases in China.

In this study, we present several sets of genetic information for PvMSP142 of populations from inland China and CMB areas at first time. We found 35 and 8 haplotypes of PvMSP142 for the isolates from Myanmar and China during 2009-2012, respectively. We also documented varied types of haplotypes characteristic of high genetic diversity in the studied region compared to other endemic regions. This high genetic diversity of PvMSP142 fragments were consistent with that of *P. vivax* field isolates collected in Cambodia and Thailand [27].

Of the 41 haplotypes, 30 were new haplotypes including 28 of them from Myanmar, characterizing of multiple clonality. The same single haplotype was documented in each of the inland isolates from Anhui compared to those of Myanmar, 2 different haplotypes from isolates from Zhejiang and diverse multiple haplotypes found in Yunnan similar to Myanmar. This finding indicated that geographical proximity between Myanmar and Yunnan China border which showed that vector dynamic and/or human motility might have been important contributing factors in malaria parasite transmission and degree of endemicity [28]. In recent years, malaria transmission has been controlled in a very low level in Anhui province, China and these cases collected here from Bengbu city were localized sporadic malaria cases [29]. These results are consistent with previous studies that genetic diversity of the malaria parasites has been shown to be associated with the levels of endemicity and transmission intensity.

Genetic diversity analysis revealed that the majority of polymorphic sites were in the 33 kDa portion and significant proportion of the identified polymorphisms occurred probably as result of reported positive selection pressure on this region while 19 kDa regions remained highly conserved. The similar results for the positive selection of PvMSP133 were reported in the *P. vivax* isolates from India and Sri Lanka several years ago [30,31]. The frequent occurrences of non-synonymous substitutions relative to synonymous ones and high value of Tajima’s D indicate the polymorphism of antigen enable parasites to avoid host immune pressure and host immune responses likely play a role in maintaining the polymorphism of *P. vivax* MSP1 alleles.

The haplotype network demonstrated that parasite populations are highly heterogeneous and dynamics of the disease transmission in these endemic areas [32]. PvMSP1 gene codes for a major malaria vaccine candidate antigen. But its polymorphic nature represents an obstacle to the design of a protective vaccine. Present study will be helpful for the development of PvMSP1 based vaccine against *P. vivax* malaria and provide evidence driven knowledge towards development of effective control interventions in Myanmar and appropriate measures in achieving China malaria elimination goals. Note-worthy, Myanmar is one of the major malaria endemic countries in the South-East Asia region, the genetic diversity of the malaria parasite circulating in CMB areas provides additional supportive information. In total, we documented 11 synonymous and 112 non-synonymous haplotypes of which 71.11% and 36.66% previously reported. Of the 11 synonymous polymorphisms, 7 were previously identified. The change might be contributed to evolutionary and/or environmental changes characterized by different patterns compared to natural and geographical studies in the Great Mekong region.

Interestingly, the network analysis of identified haplotypes
of PvMSP142 showed that most prevalent haplotypes originated from Myanmar followed by Yunnan and Zhejiang provinces of China. This information is vital and indicates that understanding the genetic diversity and network provides insights into parasite strains dynamics in the region, and design of most appropriate programmes and interventions in reducing or blocking the transmission, curving the spread of parasite as well as containment of increasing resistant strain in the Great Mekong Region.

Phylogenetic tree also showed a substantial degree of variability of the origin of the parasites. Although, all P. vivax clinical isolates, originated from the same species but analysis of these isolates showed distinct differences with the high prevalence of isolates from different countries of Myanmar, Thailand, Singapore, Bangladesh, South Korea, India, Vietnam, and Indonesia and different regions in China. Our findings are consistent with high malaria endemicity in Myanmar, where with the long borders proximity, haplotype diversity has been high comparable to the endemicity in vivax population from inland areas of China such as Anhui and Zhejiang province were lower. However, further studies on a larger population from these endemic geographic areas are required not only to determine the nationwide parasite genetic mapping and detailed malaria molecular epidemiology in CMB areas to provide evidence based decision and effective interventions [33,34].
