SET-THEORETIC ASPECTS OF ACCESSIBLE CATEGORIES

MICHAEL LIEBERMAN, JIŘÍ ROSICKÝ, AND SEBASTIEN VASEY

Abstract. An accessible category is, roughly, a category with all sufficiently directed colimits, in which every object can be resolved as a directed system of “small” subobjects. Such categories admit a purely category-theoretic replacement for cardinality: the internal size. Generalizing results and methods from [LRVa], we examine set-theoretic problems related to internal sizes and prove several Löwenheim-Skolem theorems for accessible categories. For example, assuming the singular cardinal hypothesis, we show that a large accessible category has an object in all internal sizes of high-enough cofinality. We also introduce the notion of a filtrable accessible category—one in which any object can be represented as the colimit of a chain of strictly smaller objects—and examine the conditions under which an accessible category is filtrable.

1. Introduction

Recent years have seen a burst of research activity connecting accessible categories with abstract model theory. Abstract model theory, which has always had the aim of generalizing—in a uniform way—fragments of the rich classification theory of first order logic to encompass the broader nonelementary classes of structures that abound in mathematics proper, is perhaps most closely identified with abstract elementary classes (AECs, \[She87\]), but also encompasses metric AECs (mAECs, \[HH09\]), compact abstract theories (cats, \[BY05\]), and a host of other proposed frameworks. While accessible categories appear in many areas that model theory fears to tread—homotopy theory, for example—they are, fundamentally, generalized categories of models, and the ambition to recover a portion of classification theory in this context has been present since the very beginning, \[MP89, p. 6\]. That these fields are connected has been evident for some time—the first recognition that AECs are special accessible categories came independently in \[BR12\] and \[Lie11\]—but it is only recently that a precise middle-ground has been identified: the \(\mu\)-AECs of \[BGL+16\].

While we recall the precise definition of \(\mu\)-AEC below, we note that they are a natural generalization of AECs in which the ambient language is allowed to be \(\mu\)-ary, one assumes closure only under \(\mu\)-directed unions rather than unions of arbitrary chains, and the Löwenheim-Skolem-Tarski property is weakened accordingly. The motivations for this definition were largely model-theoretic—in a typical AEC, for example, the subclass of \(\mu\)-saturated models is not an AEC, but does form a \(\mu\)-AEC—but it turns out, remarkably, that \(\mu\)-AECs are, up to equivalence, precisely the accessible categories all of whose morphisms are monomorphisms (Fact 2.12). This provides an immediate link between model- and category-theoretic analyses of problems in classification theory, a middle ground in which the tools of each discipline can be brought to bear (and, moreover, this forms the basis of a broader collection of correspondences between \(\mu\)-AECs with additional properties—universality, admitting intersections—and accessible categories with added structure—locally multipresentable, locally polypresentable \[LRV19b\]).

Among other things, this link forces a careful consideration of how one should measure the size of an object: in \(\mu\)-AECs, we can speak of the cardinality of the underlying set, but we also have a purely category-theoretic notion of internal size, which is defined—and more or less well-behaved—in any accessible category (see Definition 2.23). This is derived in straightforward fashion from the presentability rank of an object \(M\), namely the least regular cardinal \(\lambda\) (if it exists) such that any morphism sending \(M\) into the colimit of a \(\lambda\)-directed system factors through a component of the system. In most cases, the presentability rank is a successor, and the internal size is then defined to be the predecessor of the presentability rank. The latter notion generalizes, e.g. cardinality in sets (and more generally in AECs), density character in complete metric spaces, cardinality of orthonormal bases in Hilbert spaces, and minimal cardinality of a generator in classes of algebras (Example 2.24). In a sense, one upshot of \[LRV9\] is that internal size is the more suitable notion for classification theory, not least because eventual categoricity in power fails miserably, while eventual categoricity in internal size is still very much open. A related question is that of LS-accessibility: in an accessibly category \(\mathcal{K}\), is it the case...
that there is an object of internal size \( \lambda \) for every sufficiently large \( \lambda \)? Under what ambient set-theoretic assumptions, or concrete category-theoretic assumptions on \( \mathcal{K} \), does this hold? Broadly, approximations to LS-accessibility can be thought of as replacements for the Löwenheim-Skolem theorem in accessible categories. Notice that the analogous statement for cardinality fails miserably: for example, there are no Hilbert spaces whose cardinality has countable cofinality.

One broad aim of the present paper is to relate classical properties of a category (phrased in terms of limits and colimits) to the good behavior of internal sizes in this category. To properly frame these classical properties, we first recall the definition of an accessible category. For \( \lambda \) a regular cardinal, a category is \( \lambda \)-accessible if it has \( \lambda \)-directed colimits, has only a set (up to isomorphism) of \( \lambda \)-presentable objects (i.e. objects with presentability rank at most \( \lambda \)), and every object can be written as a \( \lambda \)-directed colimit of \( \lambda \)-presentable objects. A category is accessible if it is \( \lambda \)-accessible for some \( \lambda \). Note that \( \lambda \)-accessible does not always imply \( \lambda' \)-accessible for \( \lambda' > \lambda \) (see also Fact 2.9). If a given category has this property (i.e. it is accessible on a tail of regular cardinal), then we call it well accessible. In general, the class of cardinals \( \lambda \) such that a given category is \( \lambda \)-accessible (the accessibility spectrum) is a key measure of the complexity of the category. For example, accessible categories with directed colimits [BR12 4.1] or \( \mu \)-AECs with intersections [LRVa 5.4] are both known to be well accessible while general \( \mu \)-AECs need not be. In the present paper, we attempt to systematically relate the accessibility spectrum to the behavior of internal sizes. For example:

- We prove that in any well accessible category, high-enough presentability ranks have to be successors (Corollary 5.4). This holds more generally of categories where the accessibility spectrum is unbounded below weakly inaccessibles. In particular, we recover the known results that any accessible category with directed colimits [BR12 4.2], any \( \mu \)-AEC with intersections [LRVa 5.5(1)], and—assuming the singular cardinal hypothesis (SCH)—any accessible category [LRVa 3.11], has high-enough presentability ranks successor.

- We prove, assuming SCH, that in large accessible categories with all morphisms monos, for all high-enough cardinals \( \lambda \), \( \lambda^+ \)-accessibility implies existence of an object of internal size \( \lambda \) (Corollary 6.11). In this sense, the accessibility spectrum is contained in the existence spectrum. In particular, well accessible categories with all morphisms monos are LS-accessible.

- Assuming SCH, any large accessible category has objects of all internal sizes with high-enough cofinality. In particular, it is weakly LS-accessible (i.e. has objects of all high-enough regular internal sizes). This is Theorem 7.12.

Regarding the SCH assumption, we point out that we use a weaker version (“eventual SCH”, see Definition 2.16) which follows from the existence of a strongly compact cardinal [Jec03 20.8]. Thus our conclusions follow from this large cardinal axiom. In reality, we work primarily in ZFC, obtain some local results depending on cardinal arithmetic, and then apply SCH to simplify the statements. Sometimes weaker assumptions than SCH suffice, but we do not yet know whether the conclusions above hold in ZFC itself. Unsurprisingly, dealing with successors of regular cardinals is often easier, and can sometimes be done in ZFC.
Another contribution of the present account is the following: throughout the model- and set-theoretic literature, one finds countless constructions that rely on the existence of filtrations, i.e. the fact that models can be realized as the union of a continuous increasing chain of models of strictly smaller size. In a \( \lambda \)-accessible category, on the other hand, one has that any object can be realized as the colimit of a (more general) \( \lambda \)-directed system of \( \lambda \)-presentable objects, but there is no guarantee that one can extract from this system a cofinal chain consisting of objects that are also small. We here introduce the notion of well filtrable accessible category (Definition 8.5), in which the internal size analog of this essential model-theoretic property holds, and show that certain well-behaved classes of accessible categories are well filtrable. We prove general results on existence of filtrations in arbitrary accessible categories (Corollary 8.10), but really aim to study accessible categories with directed colimits. Our main result is Theorem 9.10, assuming in addition that all morphisms are monos, such categories are well filtrable. This result improves on [Ros97, Lemma 1] (which established existence of filtrations only for object of regular internal sizes) and will be used in a forthcoming paper on forking independence [LRV19b] (a follow-up to [LRV19a]).

The background required to read this paper is a familiarity with classical set theory (e.g. [Jec03, §1-8]) and basic category theory (along the lines of [AHS04]); we freely use results and terminology related to accessible categories, e.g. [AR94, MP89]. The notion of \( \mu \)-AEC, whose definition we recall below, first appears in [BGL+16]. In a sense, LRVa is also an essential prerequisite for this paper, but we nonetheless try to recall the most essential notions here to make the paper as self-contained as possible. We will also give the proof of a known result if it can be derived in a particularly straightforward way from results given here. The first few sections contain some basic model-theoretic results on \( \mu \)-AECs that nevertheless have not appeared exactly in this form before. In particular, we reprove the presentation theorem for \( \mu \)-AECs, fixing a mistake in [BGL+16, §3] reported to us by Marcos Mazari-Armida. We would like to thank him again for his thorough reading of our earlier work.

2. Preliminaries

We start by recalling the necessary set-theoretic notation.

**Definition 2.1.** Let \( \lambda \) and \( \mu \) be infinite cardinals with \( \mu \) regular.

1. For \( A \) a set, we write \([A]^{<\lambda}\) for the set of all subsets of \( A \) of cardinality strictly less than \( \lambda \), and similarly define \([A]^{\lambda}\). For \( B \) a set, we write \( B^A \) for the set of all functions from \( B \) to \( A \), and let \( ^{<\lambda}A := \bigcup_{\alpha<\lambda } \alpha A \).
2. We write \( \lambda^- \) for the predecessor of the cardinal \( \lambda \), defined as follows:
   \[
   \lambda^- = \begin{cases} 
   \theta & \text{if } \lambda = \theta^+ \\
   \lambda & \text{if } \lambda \text{ is limit}
   \end{cases}
   \]
3. We say that \( \lambda \) is \( \mu \)-closed if \( \theta^{<\mu} < \lambda \) for all \( \theta < \lambda \).
4. When we write a statement like “for all high-enough \( \theta \), ...”, we mean “there exists a cardinal \( \theta_0 \) such that for all \( \theta \geq \theta_0 \), ...”.
5. We say that SCH holds at \( \lambda \) if \( \lambda^{\text{cf}(\lambda)} = 2^{\text{cf}(\lambda)} + \lambda^+ \) (SCH stands for the singular cardinal hypothesis) — note that the equation is always true for
regular $\lambda$). We say that SCH holds above $\lambda$ if SCH holds at $\theta$ for all cardinals $\theta \geq \lambda$. The eventual singular cardinal hypothesis (ESCH) is the statement “SCH holds at all high-enough $\theta$", or more precisely “there exists $\theta_0$ such that SCH holds above $\theta_0$”.

It is a result of Solovay (see [Jec03, 20.8]) that SCH holds above a strongly compact cardinal. Thus ESCH follows from this large cardinal axiom. We will assume ESCH in several results of the present paper.

The facts below are well-known to set theorists. We give the proofs for completeness.

**Fact 2.2.**

1. If $\lambda$ is a $\mu$-closed cardinal ($\mu$ regular), then $\lambda = \lambda^{<\mu}$ if and only if $\lambda$ has cofinality at least $\mu$.
2. If SCH holds above an infinite cardinal $\theta$, then for every cardinal $\lambda$ and every regular cardinal $\mu$, $\lambda^{<\mu} \leq \lambda^+ + \sup_{\theta_0 < \theta} \theta_0^{<\mu}$. In particular, every cardinal strictly greater than $\sup_{\theta_0 < \theta} \theta_0^{<\mu}$ which is not the successor of a cardinal of cofinality strictly less than $\mu$ is $\mu$-closed.

**Proof.**

1. If $\lambda = \lambda^{<\mu}$, then $\lambda$ has cofinality at least $\mu$ by König’s theorem ($\lambda^{\text{cf}(\lambda)} > \lambda$). Conversely, if $\lambda$ has cofinality at least $\mu$ and is $\mu$-closed then $\lambda^{<\mu} = \sum_{\alpha < \lambda} |\alpha|^{<\mu} = \lambda$.
2. It suffices to prove the result when $\mu = \kappa^+$, for some infinite cardinal $\kappa$.

We proceed by induction on $\lambda$. If $\lambda < \theta$ or $\lambda < 2^\kappa$, this is clear, so assume that $\lambda \geq \theta + 2^\kappa$. If there exists $\lambda_0 < \lambda$ such that $\lambda_0^{<\mu} \geq \lambda$, we can apply the induction hypothesis, so assume that $\lambda_0^{<\mu} < \lambda$ for all $\lambda_0 < \lambda$. By [Jec03 5.20(iii)], either $\lambda^\kappa = \lambda$ or $\text{cf}(\lambda) \leq \kappa$ and $\lambda^\kappa = \lambda^{\text{cf}(\lambda)} = \lambda^+ + 2^{\text{cf}(\lambda)} < \lambda^+ + 2^\kappa = \lambda^+$ (where the second equality is by the SCH hypothesis). In both cases, we have the desired result.

For the “in particular” part, let $\lambda > \theta := \sup_{\theta_0 < \theta} \theta_0^{<\mu}$ and assume that $\lambda$ is not the successor of a cardinal of cofinality strictly less than $\mu$. We prove by induction on $\lambda$ that $\lambda$ is $\mu$-closed. If $\lambda = (\theta')^+$, then by assumption $\text{cf}(\theta') \geq \mu$ and so $(\theta')^{<\mu} = \theta'$, hence $\lambda$ is $\mu$-closed. Assume now inductively that $\lambda > (\theta')^+$ and that the result holds below $\lambda$. If $\lambda$ is a limit cardinal, then by the induction hypothesis there are cofinally-many $\mu$-closed cardinals below it and this suffices to establish that $\lambda$ is $\mu$-closed.

If $\lambda$ is a successor cardinal, say $\lambda = \lambda^+_0$, then by assumption $\text{cf}(\lambda_0) \geq \mu$. If $\lambda_0$ is $\mu$-closed, we are done by the first part. If $\lambda_0$ is not $\mu$-closed then by the induction hypothesis it must be the successor of a cardinal $\lambda_{00}$ of cofinality strictly less than $\mu$. Then by what has just been established, $\lambda_{00}^{<\mu} = \lambda_0$, so $\lambda_0^{<\mu} = \lambda_0$, as desired.

The ideas at the heart of the category-theory-enriched form of classification theory at work here, in [LRVa], and in [LRV19a], are the notions of presentability rank and internal size.

**Definition 2.3.** Let $\lambda$ and $\mu$ be infinite cardinals, $\mu$ regular, and let $\mathcal{K}$ be a category.
(1) We say that a diagram $D : I \to K$ is $\mu$-directed if $I$ is a $\mu$-directed poset (that is, every subset of size strictly less than $\mu$ has an upper bound). A $\mu$-directed colimit is just the colimit of a $\mu$-directed diagram.

(2) We say that an object $M$ in $K$ is $\mu$-presentable if the hom-functor $\text{Hom}_K(M, -) : K \to \text{Set}$ preserves $\mu$-directed colimits. Equivalently, $M$ is $\mu$-presentable if every morphism $f : M \to N$, with $N$ a $\mu$-directed colimit with cocone $\langle N_i \xrightarrow{f_i} N | i \in I \rangle$, the map $f$ factors essentially uniquely through one of the $f_i$’s.

(3) We say that $M$ is $(< \lambda)$-presentable if it is $\theta$-presentable for some regular $\theta < \lambda + \aleph_1$.

(4) The presentability rank of an object $M$ in $K$, denoted $r_K(M)$, is the smallest $\mu$ such that $M$ is $\mu$-presentable. We sometimes drop $K$ from the notation if it is clear from context.

(5) The internal size of $M$ in $K$ is defined to be $|M|_K = r_K(M)^-$. Again, we may drop $K$ from the notation if it is clear from context.

**Example 2.4.** We recall that internal size corresponds to the natural notion of size in familiar categories:

- In the category of sets, the internal size of any infinite set is precisely its cardinality. In an AEC, too, the internal size of any sufficiently big model will be its cardinality (see [Lie11, 4.3] or Fact 2.13 here).
- In the category of complete metric spaces and contractions, the internal size of any infinite space is its density character (the minimal cardinality of a dense subset). This is true, as well, for sufficiently big models in a general metric AEC, [LR17, 3.1].
- In the category of Hilbert spaces and linear contractions, the internal size of any infinite dimensional space is the cardinality of its orthonormal basis.
- In the category of free algebras with exactly one $\omega$-ary function, the internal size is the minimal cardinality of a generator. In fact, a similar characterization holds in any $\mu$-AEC with a notion of generation (i.e. with intersections), see [LRVa, 5.7].

As the above examples indicate, the relationship between internal size and cardinality can be very delicate—particularly in a context as general as $\mu$-AECs or, equivalently, accessible categories with monomorphisms (henceforth monos)—and seems to become tractable only under mild set- or category-theoretic assumptions. This is the substance of [LRVa], results of which we refine in the present paper.

We recall from [LRVa, 3.1, 3.3] an essential piece of terminology:

**Definition 2.5.** Let $\lambda$ and $\mu$ be infinite cardinals, $\mu$ regular.

1. A $(\mu, < \lambda)$-system in a category $K$ is a $\mu$-directed diagram consisting of $(< \lambda)$-presentable objects.
2. We say that a $(\mu, < \lambda)$-system with colimit $M$ is proper if the identity map on $M$ does not factor through any object in the system.

The following two results on the relationship between presentability and directedness of systems are basic.
Fact 2.6. Let $\lambda$, $\mu$, and $\theta$ be infinite cardinals, $\mu$ regular. Let $\mathcal{K}$ be a category with $\mu$-directed colimits.

(1) $[\text{LRVa}, 3.5]$ For $\lambda$ a regular cardinal, the colimit of a $(\mu, \lambda)$-system with $\theta$ objects is always $(\theta^+ + \lambda)$-presentable. In fact (for $\lambda$ not necessarily regular), if $\text{cf}(\lambda) > \theta$ and $\lambda$ is not the successor of a singular cardinal, the colimit of a $(\mu, < \lambda)$-system with $\theta$ objects is always $(< (\theta^+ + \lambda))$-presentable.

(2) $[\text{LRVa}, 3.4]$ Let $M$ be the colimit of a $(\mu, < \lambda)$-system.
(a) If $M$ is $\mu$-presentable, then the system is not proper.
(b) If the system is not proper, then $M$ is $(< \lambda)$-presentable.

We hereby obtain a criterion for the existence of objects whose presentability rank is the successor of a regular cardinal (this is already implicit in the proof of $[\text{LRVa}, 3.12]$):

Corollary 2.7. Let $\mu$ be a regular cardinal. In a category with $\mu$-directed colimits, the colimit of a proper $(\mu, \mu^+)$-system containing at most $\mu$ objects has presentability rank $\mu^+$.

Proof. Let $M$ be this colimit. By Fact 2.6(1), $M$ is $\mu^+$-presentable. By Fact 2.6(2), $M$ is not $\mu$-presentable. $\square$

The notion of a $(\mu, < \lambda)$-system also allows a more parameterized and compact rephrasing of the definition of an accessible category:

Definition 2.8. Let $\mathcal{K}$ be a category and $\lambda$ and $\mu$ be infinite cardinals, $\mu$ regular.

(1) $[\text{LRVa}, 3.6]$ We say that $\mathcal{K}$ is $(\mu, < \lambda)$-accessible if it has the following properties:
(a) $\mathcal{K}$ has $\mu$-directed colimits.
(b) $\mathcal{K}$ contains a set of $(< \lambda)$-presentable objects, up to isomorphism.
(c) Any object in $\mathcal{K}$ is the colimit of a $(\mu, < \lambda)$-system.

(2) We say that $\mathcal{K}$ is $(\mu, \lambda)$-accessible if $\lambda$ is regular and $\mathcal{K}$ is $(\mu, < \lambda^+)$-accessible. We say that $\mathcal{K}$ is $\mu$-accessible if it is $(\mu, \mu)$-accessible (this corresponds to the usual definition from, e.g. $[\text{AR94}, \text{MP89}]$). We sometimes say finitely accessible instead of $\aleph_0$-accessible.

(3) $[\text{BR12}, 2.1]$ We say that $\mathcal{K}$ is well $\mu$-accessible if it is $\theta$-accessible for each regular cardinal $\theta \geq \mu$. We say that $\mathcal{K}$ is well accessible if it is well $\mu_0$-accessible for some regular cardinal $\mu_0$.

We will use the following result, allowing us to change the index of accessibility of a category (see $[\text{MP89}, 2.3.10]$ or $[\text{LRVa}, 3.8]$):

Fact 2.9. Let $\mathcal{K}$ be a $(\mu, < \lambda)$-accessible category. If $\theta$ is a $\mu$-closed regular cardinal, then $\mathcal{K}$ is $(\theta, < (\lambda + \theta^+))$-accessible.

The following two definitions describe good behavior of the existence spectrum of an accessible category (LS-accessibility appears in $[\text{BR12}, 2.4]$, weak LS-accessibility is introduced in $[\text{LRVa}, A.1]$):

Definition 2.10. An accessible category $\mathcal{K}$ is $\text{LS-accessible}$ if it has objects of all high-enough successor presentability ranks. We say that $\mathcal{K}$ is weakly $\text{LS-accessible}$
if it has objects of all high-enough presentability ranks that are successors of regular cardinals.

Similar to an accessible category, a \( \mu \)-AEC is an abstract class of structures in which any model can be obtained by sufficiently highly directed colimits of small objects:

**Definition 2.11** ([BGL+16, §2]). Let \( \mu \) be a regular cardinal.

1. A \( (\mu \text{-ary}) \) abstract class is a pair \( (K, \leq_K) \) such that \( K \) is a class of structures in a fixed \( \mu \text{-ary} \) vocabulary \( \tau = \tau(K) \), and \( \leq_K \) is a partial order on \( K \) that respects isomorphisms and extends the \( \tau \)-substructure relation. For \( M \in K \) we write \( U_M \) for the universe of \( M \).

2. An abstract class \( K \) is a \( \mu \)-abstract elementary class (or \( \mu \)-AEC for short) if it satisfies the following three axioms:

   (a) Coherence: for any \( M_0, M_1, M_2 \in K \), if \( M_0 \subseteq M_1 \leq_K M_2 \) and \( M_0 \leq_K M_2 \), then \( M_0 \leq_K M_1 \).

   (b) Chain axioms: if \( \langle M_i : i \in I \rangle \) is a \( \mu \)-directed system in \( K \), then:

      (i) \( M := \bigcup_{i \in I} M_i \) is in \( K \).

      (ii) \( M_i \leq_K M \) for all \( i \in I \).

      (iii) If \( M_i \leq_K N \) for all \( i \in I \), then \( M \leq_K N \).

   (c) Löwenheim-Skolem-Tarski (LST) axiom: there exists a cardinal \( \lambda = \lambda^{<\mu} \geq |\tau(K)| + \mu \) such that for any \( M \in K \) and any \( A \subseteq UM \), there exists \( M_0 \in K \) with \( M_0 \leq_K M \), \( A \subseteq UM_0 \), and \( |UM_0| \leq |A|^{<\mu} + \lambda \).

   We write \( \text{LS}(K) \) for the least such \( \lambda \).

   When \( \mu = \aleph_0 \), we omit it and call \( K \) an abstract elementary class (AEC for short).

One can see any \( \mu \)-AEC \( K \) (or, indeed, any \( \mu \)-ary abstract class) as a category in a natural way: a morphism between models \( M \) and \( N \) in \( K \) is a map \( f : M \to N \) which induces an isomorphism from \( M \) onto \( f[M] \), and such that \( f[M] \leq_K N \). We abuse notation slightly: we will still use boldface when referring to this category, i.e. we denote it by \( K \) and not \( K \), to emphasize the concreteness of the category.

As mentioned in the introduction, these classes are an ideal locus of interaction between abstract model theory and accessible categories:

**Fact 2.12** ([BGL+16 §4]). Any \( \mu \)-AEC \( K \) with \( \text{LS}(K) = \lambda \) is a \( \lambda^\tau \)-accessible category with \( \mu \)-directed colimits and all morphisms monos. Conversely, any \( \mu \)-accessible category \( K \) with all morphisms monos is equivalent (as a category) to a \( \mu \)-AEC \( K \) with \( \text{LS}(K) \leq \max(\mu, \nu)^{<\mu} \), where \( \nu \) is the size of the full subcategory of \( K \) on the set of (representatives) of \( \mu \)-presentable objects.

We finish with two facts on internal sizes in \( \mu \)-AECs. The first describes the relationship between presentability and cardinality:

**Fact 2.13.** Let \( K \) be a \( \mu \)-AEC and let \( M \in K \). Then:

1. \([\text{LRA} 4.5]\) \( r_K(M) \leq |UM|^+ + \mu \).

2. If \( \lambda > \text{LS}(K) \) is a \( \mu \)-closed cardinal such that \( M \) is \( (< \lambda^+) \)-presentable, then \( |UM| < \lambda \).
Proof of (2). If \( \lambda \) is singular, we can replace \( \lambda \) by a regular \( \lambda_0 \in [\text{LS}(K)^+, \lambda) \) such that \( M \) is \( \lambda_0 \)-presentable and \( \lambda_0 \) is \( \mu \)-closed, so without loss of generality, \( \lambda \) is regular. Now apply [LRVa 4.8, 4.9].

The second gives a sufficient condition for existence of objects of presentability rank the successor of a regular cardinal. The proof is very short given what has already been said, so we give it.

**Fact 2.14** ([LRVa 3.12]). Let \( \lambda \) and \( \mu \) be infinite cardinals with \( \mu \) regular. If \( K \) is a \((\mu, < \lambda)\)-accessible category with all morphisms monos and \( K \) has an object that is not \((< \lambda)\)-presentable, then \( K \) has a proper \((\mu, < \lambda)\)-system with \( \mu \) objects. In particular, if in addition \( \lambda \leq \mu^{++} \), then \( K \) has an object of presentability rank \( \mu^+ \).

**Proof.** Let \( N \) be an object of \( K \) that is not \((< \lambda)\)-presentable. Since \( K \) is \((\mu, < \lambda)\)-accessible, \( N \) is the colimit of a \((\mu, < \lambda)\)-system \( \langle N_i : i \in I \rangle \). Since \( N \) is not \((< \lambda)\)-presentable, the system is proper (Fact 2.6(2)). Since \( I \) is \( \mu \)-directed and all morphisms of \( K \) are monos, we can pick a strictly increasing chain \( \langle i_k : k < \mu \rangle \) inside \( I \) such that \( (M_{i_k} : k < \mu) \) is still proper. This then gives the desired proper \((\mu, < \lambda)\)-system with \( \mu \) objects. The “in particular” part follows from Corollary 2.14. 

### 3. Directed systems and cofinal posets

As observed in [BGL+16 4.1], if \( K \) is a \( \mu \)-AEC then any \( M \in K \) is the \( \text{LS}(K)^+ \)-directed union of all its \( K \)-substructures of cardinality at most \( \text{LS}(K) \). In an AEC (i.e. when \( \mu = \aleph_0 \)), it is well known that furthermore one can write \( M = \bigcup_{s \in [U_M] < \mu} M_s \), where the \( M_s \)'s form a \( \mu \)-directed system of objects of cardinality at most \( \text{LS}(K) \), and \( s \subseteq UM_s \) for all \( s \). In the proof of [BGL+16 3.2], it was asserted without proof that the corresponding statement was also true when \( \mu > \aleph_0 \). This was a key ingredient of the proof of the presentation theorem there. It was pointed out to us (by Marcos Mazari-Armida) that the proof for AECs does not generalize to \( \mu \)-AECs: since we cannot take unions, there are problems at limit steps. Thus we in fact do not know whether the statement is still true for \( \mu \)-AECs. In this section, we prove a weakening and in the next two sections reprove the presentation theorem and related axiomatizability results.

We will more generally develop the theory of subposets of posets that are cofinal in a generalized sense:

**Definition 3.1.** A partially ordered set (or poset) is a binary relation \( (P, \leq) \) which is transitive, reflexive, and antisymmetric. We may not always explicitly mention \( \leq \). A subposet of a partially ordered set \( P \) is a poset \((P^*, \leq^*)\) with \( P^* \subseteq P \) and \( x \leq^* y \) implying \( x \leq y \).

**Definition 3.2.** For \( \theta \) a cardinal, a subposet \( P^* \) of a poset \( P \) is \( \theta \)-cofinal if for any \( p \in P \) and any sequence \( \langle p_i : i < \theta \rangle \) of elements of \( P^* \) with \( p_i \leq p \) for all \( i < \theta \), there exists \( q \in P^* \) such that \( p \leq q \) and \( p_i \leq^* q \) for all \( i < \theta \). We say that \( P^* \) is \((< \theta)\)-cofinal if it is \( \theta_0 \)-cofinal for all \( \theta_0 < \theta \).

**Remark 3.3.** If \( P^* \) is \( \theta \)-cofinal in \( P \), then it is \( \theta_0 \)-cofinal in \( P \) for all \( \theta_0 < \theta \).
Note that $P^*$ is 0-cofinal if and only if it is cofinal in $P$ as a set. Being 1-cofinal means that if $p_0 \leq p$ with $p \in P$ and $p_0 \in P^*$, there exists $q \in P^*$ so that $p \leq q$ and $p_0 \leq^* q$. If $P^*$ is 1-cofinal, an induction shows that it is automatically $n$-cofinal for all $n < \omega$ (a similar argument appears in [SV, 3.9]). More generally, we can get that it is $\theta$-cofinal assuming chain bounds:

**Definition 3.4.** For an ordinal $\alpha$, a poset $P$ has $\alpha$-chain bounds if any chain $\langle p_i : i < \alpha \rangle$ in $P$ has an upper bound. We say that $P$ has $(< \alpha)$-chain bounds if it has $\beta$-chain bounds for all $\beta < \alpha$. Similarly define $(\leq \alpha)$-chain bounds.

**Remark 3.5.** Any poset has $\alpha$-chain bounds for $\alpha$ a successor or zero (when the poset is not empty). When $\alpha$ is limit, $\alpha$-chain bounds is equivalent to $\text{cf}(\alpha)$-chain bounds.

**Lemma 3.6.** Let $\theta$ be a cardinal and let $P^*$ be a suposet of a poset $P$. If $P^*$ is 1-cofinal in $P$ and $P^*$ has $(\leq \theta)$-chain bounds, then $P^*$ is $\theta$-cofinal in $P$.

**Proof.** Let $p \in P$ and $\langle p_i : i < \theta \rangle$ be below $p$ and in $P^*$. We proceed by induction on $\theta$. If $\theta \leq 1$, the result is true by assumption. Assume now that $\theta > 1$ and the result holds for all $\theta_0 < \theta$. We build an increasing chain $\langle q_i : i < \theta \rangle$ in $P^*$ such that $p \leq q_0$ and for all $j < i < \theta$, $p_j \leq^* q_i$. This is possible by successive use of the induction hypothesis and 1-cofinality (at limits, use the chain bound assumption). Now take $q \in P^*$ $\leq^*$-above each $q_i$. $\square$

Definition 3.2 helps us understand the relationship between $\theta$-directedness of $P^*$ and $P$. One direction is easy:

**Lemma 3.7.** Let $P^*$ be a 0-cofinal suposet of a poset $P$ and let $\theta$ be an infinite cardinal. If $P^*$ is $\theta$-directed, then $P$ is $\theta$-directed.

**Proof.** Let $\{p_i : i \in I\}$ be a subset of $P$ of cardinality strictly less than $\theta$. Using 0-cofinality, pick for each $i \in I$ a $q_i \in P^*$ such that $p_i \leq q_i$. Then use that $P^*$ is $\theta$-directed to find $q \in P^*$ with $q_i \leq^* q$. This is the desired upper bound for $\{p_i : i \in I\}$ in $P$. $\square$

The other direction uses the extended notion of being cofinal:

**Lemma 3.8.** Let $\theta$ be an infinite cardinal and let $P^*$ be a $(< \theta)$-cofinal suposet of $P$. If $P$ is $\theta$-directed, then $P^*$ is $\theta$-directed.

**Proof.** Let $\theta_0 < \theta$ and $\langle p_i : i < \theta_0 \rangle$ be elements of $P^*$. By $\theta$-directedness of $P$, there exists $p \in P$ with $p_i \leq p$ for all $i < \theta_0$. Since $P^*$ is $\theta_0$-cofinal in $P$, there exists $q \in P^*$ such that $p \leq q$ and $p_i \leq^* q$ for all $i < \theta_0$. $\square$

The next result extracts, from a diagram in $P$, a certain cofinal extension of that diagram in $P^*$. It will be applied to $\mu$-AECs.

**Theorem 3.9.** Let $\theta$ be an infinite cardinal, let $P$ be a $\theta$-directed poset, and let $P^*$ be a $(< \theta)$-cofinal suposet of $P$. Let $(I, \leq)$ be a partial order and let $\langle p_i : i \in I \rangle$ be a diagram in $P$ (that is, if $i \leq j$ are in $I$, then $p_i \leq p_j$). If for all $i \in I$, $|\{j \in I \mid j < i\}| < \theta$, then there exists $I_0 \subseteq I$ cofinal and a diagram $\langle q_i : i \in I_0 \rangle$ in $P^*$ such that for all $i \in I_0$, $p_i \leq q_i$. $\square$
Proof. We define a new poset $\mathcal{F}$. Its objects are diagrams $\langle q_i : i \in I_0 \rangle$ in $\mathbb{P}^*$, with $I_0 \subseteq I$ (not necessarily cofinal) and with $p_i \leq q_i$ for all $i \in I_0$. Order $\mathcal{F}$ by extension. Now $\mathcal{F}$ is not empty (the empty diagram is in $\mathcal{F}$) and every chain in $\mathcal{F}$ has an upper bound (its union). By Zorn’s lemma, there is a maximal element $\langle q_i : i \in I_0 \rangle$ in $\mathcal{F}$. We show that $I_0$ is cofinal in $I$. Suppose not and let $i^* \in I$ be such that $i^* \not\leq j$ for any $j \in I_0$.

Since $\mathbb{P}^*$ is 0-cofinal in $\mathbb{P}$, there exists $p_{i^*}$ in $\mathbb{P}^*$ such that $p_i \leq p_{i^*}$. Consider the set $Q := \{ p_{i^*} \} \cup \{ q_i \mid i \in I_0, i < i^* \}$. Note that $|Q| < \theta$ and by Lemma 3.8, $\mathbb{P}^*$ is $\theta$-directed, so pick $q_{i^*} \in \mathbb{P}^*$ an upper bound for $Q$.

Consider $\langle q_i : i \in I_0 \cup \{ i^* \} \rangle$. We show this is an element of $\mathcal{F}$, contradicting the maximality of $\langle q_i : i \in I_0 \rangle$. First, it is clear from the definition that $p_i \leq q_i$ for all $i \in I_0 \cup \{ i^* \}$. It remains to see that $\langle q_i : i \in I_0 \cup \{ i^* \} \rangle$ is a diagram in $\mathbb{P}^*$.

So let $i \leq j$ be two elements of $I_0 \cup \{ i^* \}$. If $i, j \in I_0$, then we are done by the assumption that $\langle q_i : i \in I_0 \rangle$ is a diagram. Thus at least one of $i$ or $j$ is equal to $i^*$. If $i = j = i^*$, then since $q_{i^*} \in \mathbb{P}^*$ we are also done. If $i \in I_0$ and $j = i^*$, we have made sure in the construction that $q_i \leq q_j$. Finally, we cannot have that $i = i^*$ and $j \in I_0$ by the choice of $i^*$ (a witness to the non-cofinality of $I_0$).

As an application, we can study sufficiently closed objects $M$ in an abstract class. While we may not be able to resolve such an object with a system indexed by $[UM]<^\theta$, we can at least get a system indexed by a cofinal subset of $[UM]<^\theta$.

Definition 3.10. Let $K$ be an abstract class and let $\theta$ be an infinite cardinal. An object $M \in K$ is $\theta$-closed if for any $A \in [UM]<^\theta$, there exists $M_0 \in K$ with $M_0 \leq_K M$, $A \subseteq UM_0$, and $|UM_0| < \theta$.

Corollary 3.11. Let $K$ be an abstract class, let $\theta$ be an infinite cardinal, and let $M \in K$ be $\theta$-closed. Let $I \subseteq [UM]<^\theta$ be such that for any $s \in I$, $|P(s) \cap I| < \text{cf}(\theta)$. Then there exists $I_0 \subseteq I$ and $\{ M_s : s \in I_0 \}$ such that $I_0$ is cofinal in $I$ and for any $s, t \in I_0$:

1. $M_s \subseteq M$.
2. $|UM_s| < \theta$.
3. $s \subseteq UM_s$.
4. $s \subseteq t$ implies $UM_s \subseteq UM_t$.

Proof. Let $\mathbb{P}$ be the partially ordered set $[UM]<^\theta$, ordered by subset inclusion. Note that $\mathbb{P}$ is $\theta$-directed. Let $\mathbb{P}^*$ be the partially ordered set $\{ UM_0 \mid M_0 \in K, M_0 \leq_K M, \text{cf}(UM_0) < \theta \}$, also ordered by subset inclusion. It is easy to check that $\mathbb{P}^*$ is a subposet of $\mathbb{P}$. It is also straightforward to see that $\mathbb{P}^*$ is 1-cofinal in $\mathbb{P}$ (using that $M$ is $\theta$-closed). Similarly, $\mathbb{P}^*$ has ($< \text{cf}(\theta)$)-chain bounds. By Lemma 3.8, $\mathbb{P}^*$ is ($< \text{cf}(\theta)$)-cofinal in $\mathbb{P}$. Apply Theorem 3.9 with $\theta$ there being $\text{cf}(\theta)$ here and $p_s = s$ for each $s \in I$.

As an application of Corollary 3.11, we study what happens if we weaken the Löwenheim-Skolem-Tarski (LST) axiom of $\mu$-AECs to the “weak LST axiom”: there exists a cardinal $\lambda \geq |\tau(K)| + \mu$ such that $\lambda = \lambda^{<\mu}$ and every object of $K$ is $\lambda$-closed (i.e. for all $M \in K$ and all $A \subseteq UM$ of cardinality at most $\lambda$, there exists $M_0 \in K$ with $M_0 \leq_K M$, $|UM| \leq \lambda$, and $A \subseteq UM$). It was shown in [BGL+16, 4.6]
that such a weakening still implies the original LST axiom, but the proof did not
give that the minimal \( \lambda \) satisfying the weak LST axiom should be the Löwenheim-
Skolem-Tarski number. We prove this now.

**Corollary 3.12.** Let \( \mu \) be a regular cardinal, let \( K \) be an abstract class satisfying
the coherence and chain axioms of \( \mu \)-AECs, and let \( \lambda \) be an infinite cardinal. If
\( \lambda = \lambda^\lt \mu \) and any element of \( K \) is \( \lambda^+ \)-closed, then \( K \) is a \( \mu \)-AEC with \( \text{LS}(K) \leq \lambda \).

**Proof.** Let \( M \in K \) and let \( A \subseteq UM \). Apply Corollary 3.11 with \( I := [A]^{<\mu} \) and
\( \theta := \lambda^+ \) (note that \( 2^{<\mu} \leq \lambda^{<\mu} = \lambda < \theta \), so the cardinal arithmetic condition there
is satisfied). Let \( \langle M_s : s \in I_0 \rangle \) be as given there. This is a \( \mu \)-directed system by
coherence, so let \( N \) be its union. By construction, \( N \leq M \) and \( A \subseteq UN \). Moreover,
\( |UN| \leq |I_0| \cdot \lambda \leq |A|^{<\mu} + \lambda \), as needed. \( \square \)

4. Presentation theorem and axiomatizability

We reprove here the presentation theorem for \( \mu \)-AECs (and more generally for
accessible categories with \( \mu \)-directed colimits and all morphisms monos), in the
form outlined and motivated in [LRV19b, §6] (there, additional assumptions on the
existence of certain directed colimits had to be inserted to make the proof work).
The idea is simple: any \( \mu \)-accessible category is equivalent to the category of models
of an \( L_{\infty,\mu} \)-sentence, and we can Skolemize such a sentence to obtain the desired
functor. We first state the three facts we will use. Recall that \( \text{Mod}(\phi) \) denotes
the category of models of the sentence \( \phi \), with morphisms all homomorphisms (i.e.
maps preserving functions and relations). See also [LRV19b, §4] for a summary of
what is known on axiomatizability of accessible categories.

**Fact 4.1** ([MP89, 3.2.3, 3.3.5, 4.3.2]). Any \( \mu \)-accessible category is equivalent to
\( \text{Mod}(\phi) \), for \( \phi \) an \( L_{\infty,\mu} \)-formula.

Recall [LRV19b] 2.1 that (for a regular cardinal \( \mu \)) a \( \mu \)-universal class is a class of
structures in a \( \mu \)-ary vocabulary that is closed under isomorphisms, substructure,
and \( \mu \)-directed unions.

**Fact 4.2** (Skolemization). Let \( \mu \leq \lambda \). If \( \phi \) is an \( L_{\lambda^+,\mu} \)-sentence in the vocabulary
\( \tau \), there exists an expansion \( \tau^+ \) of \( \tau \) with function symbols and a \( \mu \)-universal class
\( K^+ \) with vocabulary \( \tau^+ \) such that:

1. \( |\tau^+| \leq \lambda \).
2. The reduct map is a faithful functor from \( K^+ \) into \( \text{Mod}(\phi) \) that is surjective
   on objects and preserves \( \mu \)-directed colimits.

**Proof sketch.** Let \( \Phi \) be a fragment (i.e. set of formulas in \( L_{\lambda^+,\mu} \) closed under sub-
formulas) which contains \( \phi \) and has cardinality at most \( \lambda \). Add a Skolem function
for each formula in \( \Phi \), forming a vocabulary \( \tau^+ \), and let \( K^+ \) be the set of all \( \tau^+ \)-
structures whose reduct is a model of \( \phi \) and where the Skolem functions perform
as expected. \( \square \)

The result below was stated for \( \mu = \aleph_0 \) in [LR16 2.5], but the proof easily generalizes.
Fact 4.3 ([LR16, 2.5]). If \( K \) is an accessible category with \( \mu \)-directed colimits and all morphisms monos, then there exists a \( \mu \)-accessible category \( L \) and a faithful essentially surjective functor \( F : L \to K \) preserving \( \mu \)-directed colimits. In fact, if \( K \) is \( \lambda \)-accessible, \( L \) is the free completion under \( \mu \)-directed colimits of the full subcategory of \( K \) induced by its \( \lambda \)-presentable objects.

Theorem 4.4 (The presentation theorem for \( \mu \)-AECs). If \( K \) is an accessible category with \( \mu \)-directed colimits and all morphisms monos, then there exists a \( \mu \)-universal class \( L \) and an essentially surjective faithful functor \( F : L \to K \) preserving \( \mu \)-directed colimits.

Proof. By Fact 4.3 there exists a \( \mu \)-accessible category \( K^1 \) and a faithful essentially surjective functor \( F^1 : K^1 \to K \). By Fact 4.1 \( K^1 \) is equivalent to \( \text{Mod}(\phi) \), for some \( L_{\infty, \mu} \)-sentence \( \phi \). Since all morphisms are monos, we may assume that non-equality is part of the vocabulary of \( \phi \). By Fact 4.2 we can find a \( \mu \)-universal class \( K^+ \) so that the reduct map \( F^0 : K^+ \to \text{Mod}(\phi) \) is an essentially surjective faithful functor preserving \( \mu \)-directed colimits. Set \( L := K^+, F := F^1 \circ F^0 \).

Note that if we apply Theorem 4.4 to a \( \mu \)-AEC \( K \), the functor is not directly given by a reduct from some expansion of \( K \) (we first have to pass through several equivalence of categories). Thus Theorem 4.4 does not immediately prove (as in [Bon14] for AECs) that \( \mu \)-AECs are closed under sufficiently complete ultraproducts. For this, we will prove that a certain functorial expansion of the \( \mu \)-AEC is axiomatizable by an infinitary logic (without passing to an equivalent category):

Definition 4.5. Let \( K \) be a \( \mu \)-AEC. The substructure functorial expansion of \( K \) is the abstract class \( K^+ \) defined as follows:

1. \( \tau(K^+) = \tau(K) \cup \{ P \} \), where \( P \) is an \( \text{LS}(K) \)-ary predicate.
2. \( M^+ \in K^+ \) if and only if \( M^+ \upharpoonright \tau(K) \in K \) and for any \( \bar{a} \in \text{LS}(K) M^+ \), \( P^{M^+}(\bar{a}) \) holds if and only if \( \text{ran}(\bar{a}) \leq K M^+ \upharpoonright \tau(K) \), where we see \( \text{ran}(\bar{a}) \) as a \( \tau(K) \)-structure.
3. For \( M^+, N^+ \in K^+ \), \( M^+ \leq_{\text{K}} N^+ \) if and only if \( M^+ \upharpoonright \tau(K) \leq_{\text{K}} N^+ \upharpoonright \tau(K) \).

The substructure expansion is "functorial" in the sense of [Vas16, 3.1]: the reduct functor gives an isomorphism of concrete categories. The substructure functorial expansion has the property of having very simple morphisms:

Theorem 4.6. Let \( K \) be a \( \mu \)-AEC and let \( K^+ \) be its substructure functorial expansion. If \( M^+, N^+ \in K^+ \) are such that \( M^+ \subseteq N^+ \), then \( M^+ \leq_{\text{K}} N^+ \).

Proof. For \( M \in K \), write \( M^+ \) for the expansion of \( M \) to \( K^+ \). Let \( M, N \in K \) and assume that \( M^+ \subseteq N^+ \). We have to see that \( M \leq_{\text{K}} N \). For this, it is enough to show that for any \( M_0 \leq_{\text{K}} M \) of cardinality at most \( \text{LS}(K) \), we also have that \( M_0 \leq_{\text{K}} N \) (indeed, we can then take the \( \text{LS}(K)^+ \)-directed union of all such \( M_0 \)'s). So let \( M_0 \leq_{\text{K}} M \) have cardinality at most \( \text{LS}(K) \): we must show that \( M_0 \leq_{\text{K}} N \). Let \( \bar{a} \) be an enumeration of \( M_0 \). We have that \( M^+ \models P[\bar{a}] \) (where \( P \) is the additional predicate in \( \tau(K)^+ \)), so \( N^+ \models P[\bar{a}] \) (as \( M^+ \) is a substructure of \( N^+ \)). This means that \( M_0 \leq_{\text{K}} N \), as desired. \( \square \)
The substructure functorial expansion of a \( \mu \)-AEC can be axiomatized (a more complication variation of this, for AECs, is due to Baldwin and Boney [BB17, 3.9]). Since the ordering is trivial by the previous result, this shows that any \( \mu \)-AEC is isomorphic (as a category) to the category of models of an \( \mathbb{L}_{\infty, \infty} \) sentence, where the morphisms are injective homomorphisms.

**Theorem 4.7.** Let \( K \) be a \( \mu \)-AEC and let \( K^+ \) be its substructure functorial expansion. There is an \( \mathbb{L}^{(\mathbb{L}_{\text{LS}(K)}^+, \mathbb{L}_{\text{LS}(K)}^+)+} \) sentence \( \phi \) such that \( K^+ \) is the class of models of \( \phi \).

**Proof.** First note that for each \( M_0 \in K_{\leq \mathbb{L}_{\text{LS}(K)}} \), there is a sentence \( \psi_{M_0}(\bar{x}) \) of \( \mathbb{L}_{\text{LS}(K)}^+, \mathbb{L}_{\text{LS}(K)}^+ \) coding its isomorphism type, i.e. whenever \( M \models \psi_{M_0}[\bar{a}] \), then \( \bar{a} \) is an enumeration of an isomorphic copy of \( M_0 \). Similarly, whenever \( M_0, M_1 \) are in \( K_{\leq \mathbb{L}_{\text{LS}(K)}} \) with \( M_0 \leq_K M_1 \), there is \( \psi_{M_0,M_1}(\bar{x}, \bar{y}) \) that codes that \( (\bar{x}, \bar{y}) \) is isomorphic to \( (M_0, M_1) \) (so in particular \( \bar{x} \leq_K \bar{y} \)). Let \( S \) be a complete set of members of \( K_{\leq \mathbb{L}_{\text{LS}(K)}} \) (i.e. any other model is isomorphic to it) and let \( T \) be a complete set of pairs \((M_0, M_1)\), with each in \( K_{\leq \mathbb{L}_{\text{LS}(K)}} \), such that \( M_0 \leq_K M_1 \). Now define the following:

\[
\phi_1 = \forall \bar{x} \exists \bar{y} \left( \bigvee_{M_0 \in S} \psi_{M_0}(\bar{y}) \land \bar{x} \subseteq \bar{y} \land P(\bar{y}) \right)
\]

\[
\phi_2 = \forall \bar{x} \forall \bar{y} \left( (\bar{x} \subseteq \bar{y} \land P(\bar{x}) \land P(\bar{y})) \rightarrow \bigvee_{(M_0, M_1) \in T} \psi_{M_0,M_1}(\bar{x}, \bar{y}) \right)
\]

\[
\phi = \phi_1 \land \phi_2
\]

Where \( \bar{x} \subseteq \bar{y} \) abbreviates the obvious formula. This works. First, any \( M^+ \in K^+ \) satisfies \( \phi_1 \) by the LST axiom and satisfies \( \phi_2 \) by the coherence axiom. Conversely, assume that \( M^+ \models \phi \) and let \( M := M^+ \upharpoonright \tau(K) \). Consider the set:

\[
I = \{ M_0 \in K_{\leq \mathbb{L}_{\text{LS}(K)}} \mid UM_0 \subseteq UM, P^{M^+}(\bar{M}_0) \}
\]

Where \( \bar{M}_0 \) refers to some enumeration of \( M_0 \). Then by construction of \( \phi \), \( I \) is a \( \mu \)-directed system in \( K \) and \( \bigcup I = M \), so \( M \in K \). Similarly, \( P^{M^+}(\bar{a}) \) holds if and only if \( \text{ran}(\bar{a}) \leq_K M \), so \( M^+ \in K^+ \).

**Corollary 4.8.** Any \( \mu \)-AEC \( K \) is closed under \( (\mathbb{L}_{\text{LS}(K)}^+, \mathbb{L}_{\text{LS}(K)}^+)^+ \)-complete ultraproducts (in the sense that the appropriate generalization of [Bon14, 4.3] holds).

**Proof.** By Theorems 4.6 and 4.7, Loś’ theorem, and the fact that taking reducts commutes with ultraproducts.

\[\square\]
5. On successor presentability ranks

We start our study of the existence spectrum of an accessible category $\mathcal{K}$: the set of regular cardinals $\lambda$ such that $\mathcal{K}$ has an object of presentability rank $\lambda$. The goal is to say as much as possible by just looking at the accessibility spectrum: the set of cardinals $\lambda$ such that $\mathcal{K}$ is $\lambda$-accessible.

In this section, we consider the question, first systematically investigated in [BR12], of whether the presentability rank of an object always has to be a successor (or, said differently, whether there can be objects of weakly inaccessible presentability rank). Assuming the accessibility spectrum is sufficiently large, we show there are no objects of weakly inaccessible presentability rank, and explain how this generalizes previous results.

The following easy lemma characterizes existence in terms of the accessibility spectrum. It will also be used in the next section:

**Lemma 5.1.** Let $\lambda$ be a regular cardinal and let $\mathcal{K}$ be a category. The following are equivalent:

1. $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible.
2. $\mathcal{K}$ is $\lambda$-accessible and has no objects of presentability rank $\lambda$.

**Proof.** Assume $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible. By definition, $\mathcal{K}$ is clearly $\lambda$-accessible. If $M$ is a $\lambda$-presentable object of $\mathcal{K}$, then it is a $\lambda$-directed colimit of $(< \lambda)$-presentable objects, hence by Fact 2.6 must itself be $(< \lambda)$-presentable.

Conversely, if $\mathcal{K}$ is $\lambda$-accessible and has no objects of presentability rank $\lambda$, then any $(\lambda, \lambda)$-system must be a $(\lambda, < \lambda)$-system, hence $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible. □

The following new result gives a criterion for $(\lambda, < \lambda)$-accessibility when $\lambda$ is weakly inaccessible.

**Theorem 5.2.** If $\lambda$ is weakly inaccessible and $\mathcal{K}$ is $(\mu, < \lambda)$-accessible for unboundedly many $\mu < \lambda$, then $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible.

**Proof.** Let $S$ be the set of all regular cardinals $\mu < \lambda$ such that $\mathcal{K}$ is $(\mu, < \lambda)$-accessible. Let $M$ be an object of $\mathcal{K}$. For each $\mu \in S$, fix a $\mu$-directed system $\langle M_\mu^i : i \in I_\mu \rangle$, with maps $\{ f_{i,j}^\mu : i \leq j \in I_\mu \}$ whose colimit is $M$ (with colimit maps $f_i^\mu$, $i \in I_\mu$). Let $I := \{(i, \mu) \mid \mu \in S, i \in I_\mu\}$. Order it by $(i, \mu_1) \leq (j, \mu_2)$ if and only if $\mu_1 \leq \mu_2$, and there exists a unique map $g : M_{i,\mu_1}^\mu \to M_{j,\mu_2}^\mu$ so that $f_i^\mu = f_j^\mu g$.

Observe that $(I, \leq)$ is a partial order. Also, if we fix $\mu \in S$ and $i \in I_\mu$, then $M_\mu^i$ is $(< \lambda)$-presentable, hence $\mu_1$-presentable for some regular $\mu_1 \in S$, $\mu \leq \mu_1$. Thus for any $\mu_2 \in S$ with $\mu_1 \leq \mu_2$, there exists $j \in I_{\mu_2}$ such that $(i, \mu) \leq (j, \mu_2)$.

The last paragraph quickly implies that $I$ is $\lambda$-directed, and so the diagram induced by $I$ is the desired $(\lambda, < \lambda)$-system with colimit $M$. □

**Corollary 5.3.** If $\lambda$ is weakly inaccessible and $\mathcal{K}$ is $\mu$-accessible for unboundedly many $\mu < \lambda$, then $\mathcal{K}$ does not have an object of presentability rank $\lambda$.

**Proof.** By Theorem 5.2 $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible. Now apply Lemma 5.1. □
We obtain that any high-enough presentability rank in a well-accessible category (recall Definition 2.8(3)) must be a successor, which improves on [BR12, 4.2] and [LRVa, 5.5]:

**Corollary 5.4.** If $\mathcal{K}$ is a well-$\mu$-accessible category, then the presentability rank of any object that is not $\mu$-presentable must be a successor.

*Proof.* Immediate from Corollary 5.3.

We have also recovered [LRVa, 3.11]:

**Corollary 5.5.** Let $\mu$ be a regular cardinal and let $\lambda > \mu$ be a weakly inaccessible cardinal. If $\mathcal{K}$ is a $(\mu, < \lambda)$-accessible category and $\lambda$ is $\mu$-closed, then $\mathcal{K}$ has no object of presentability rank $\lambda$.

In particular, assuming ESCH, high-enough presentability ranks are successors in any accessible category.

*Proof.* Since $\lambda$ is $\mu$-closed and limit, there are unboundedly-many regular $\theta \in [\mu, \lambda)$ that are $\mu$-closed. By Fact 2.6, for any such $\theta$, $\mathcal{K}$ is $(\theta, < \lambda)$-accessible. By Theorem 5.2, $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible, hence by Lemma 5.1 cannot have an object of presentability rank $\lambda$.

## 6. The existence spectrum of a $\mu$-AEC

We now refine a few results of [LRVa] concerning the existence spectrum of $\mu$-AECs, especially [LRVa, 4.13].

We aim to study proper $(\lambda, < \lambda)$-systems—in the sense of Definition 2.5—and show that under certain conditions they do not exist. This will give conditions under which an object of presentability rank $\lambda$ does exist:

**Lemma 6.1.** Let $\lambda$ be a regular cardinal and let $\mathcal{K}$ be a $\lambda$-accessible category. If $\mathcal{K}$ has an object that is not $(< \lambda)$-presentable and $\mathcal{K}$ has no proper $(\lambda, < \lambda)$-systems, then $\mathcal{K}$ has an object of presentability rank $\lambda$.

*Proof.* By Lemma 5.1 it suffices to show that $\mathcal{K}$ is not $(\lambda, < \lambda)$-accessible. Suppose for a contradiction that $\mathcal{K}$ is $(\lambda, < \lambda)$-accessible. Let $M$ be an object that is not $(< \lambda)$-presentable. Then $M$ is the colimit of a $(\lambda, < \lambda)$-system, which must be proper because $M$ is not $(< \lambda)$-presentable (see Fact 2.6), a contradiction to the assumption that there are no proper $(\lambda, < \lambda)$-systems.

To help the reader, let us consider what a $(\lambda^+, < \lambda^+)$-system should be in an AEC $\mathcal{K}$ with $\lambda > \text{LS}(\mathcal{K})$. Since internal sizes correspond to cardinalities in that context (see Fact 2.13 or simply [Lie11, 4.3]), such a system must be a $\lambda^+$-directed system consisting of object of cardinality strictly less than $\lambda$. Because it is “too directed,” the system cannot be proper (i.e. its colimit will just be a member of the system). We attempt here to generalize such an argument to suitable $\mu$-AECs. We will succeed when $\lambda$ is $\mu$-closed (Theorem 6.10 — notice that this is automatic when $\mu = \aleph_0$).

We will use the following key bound on the internal size of a subobject:
**Lemma 6.2.** If $K$ is a $\mu$-AEC, $M \leq_K N$ are in $K$, $\lambda > \text{LS}(K)$ is a $\mu$-closed cardinal, and $N$ is $(< \lambda^+)$-presentable, then $M$ is $(< \lambda^+)$-presentable.

**Proof.** By Fact 2.13, $|UN| < \lambda$. Of course, $|UM| \leq |UN|$, so $UM < \lambda$. By Fact 2.13 again, $r_K(M) \leq |UM|^+ + \mu$, so $r_K(M) \leq \lambda + \mu = \lambda$, so $M$ is $(< \lambda^+)$-presentable, as desired. \qed

We require an additional refinement, concerning systems in which bounded subsystems have small colimits:

**Definition 6.3.** A system $\langle M_i : i \in I \rangle$ in a given category is *boundedly $(< \lambda)$-presentable* if whenever $I_0 \subseteq I$ is bounded in $I$, the colimit of $\langle M_i : i \in I_0 \rangle$ is $(< \lambda)$-presentable (whenever it exists).

**Lemma 6.4.** Let $K$ be a $\mu$-AEC and let $\lambda > \text{LS}(K)^+$ be such that $\lambda^-$ is $\mu$-closed. Then any system in $K$ consisting of $(< \lambda)$-presentable objects is boundedly $(< \lambda)$-presentable.

**Proof.** Let $\langle M_i : i \in I \rangle$ be a system consisting of $(< \lambda)$-presentable objects. Let $I_0 \subseteq I$ be bounded in $I$, say by $i$, and such that the colimit $M_{I_0}$ of the resulting system exists. We have that $M_{I_0} \leq_K M_i$. Since $\lambda^-$ is $\mu$-closed and $M_i$ is $(< \lambda)$-presentable, we can find $\lambda_0 \in [\text{LS}(K), \lambda)$ regular and $\mu$-closed such that $M_i$ is $\lambda_0$-presentable. By Lemma 6.2, $M_{I_0}$ is also $\lambda_0$-presentable, hence $(< \lambda)$-presentable, as desired. \qed

Using the bound of Lemma 6.2 again, we now show that for most successor cardinals $\theta$, there are no proper $\theta$-directed boundedly $(< \theta)$-presentable systems:

**Lemma 6.5.** Let $K$ be a $\mu$-AEC. If $\lambda > \text{LS}(K)$ is $\mu$-closed, then there are no proper $\lambda^+$-directed boundedly $(< \lambda^+)$-presentable systems.

**Proof.** Assume for a contradiction that $\langle M_i : i \in I \rangle$ is such a system, with colimit $M$. First, if $\lambda$ is regular, then using $\lambda^+$-directedness and properness we can find a chain $I_0 \subseteq I$ of type $\lambda$ such that $i < j$ in $I_0$ implies $M_i \neq M_j$. Then $\langle M_i : i \in I_0 \rangle$ is proper, so its colimit (union) $M_{I_0}$ is not $\lambda$-presentable (Fact 2.6). However, $I_0$ is bounded as $I$ is $\lambda^+$-directed, a contradiction to the hypothesis of bounded $(< \lambda^+)$-presentability.

Assume now that $\lambda$ is singular. Let $\delta := \text{cf}(\lambda)$ and write $\lambda = \sup_{\alpha < \delta} \lambda_\alpha$, with $\text{LS}(K) < \lambda_0$ and each $\lambda_\alpha$ regular and $\mu$-closed. Let $I_\alpha := \{ i \in I \mid M_i \in \lambda_\alpha\text{-presentable} \}$. Note that $I = \bigcup_{\alpha < \delta} I_\alpha$.

We claim that there exists $\alpha < \delta$ such that $I_\alpha$ is cofinal in $I$. Suppose not, and for each $\alpha < \delta$ pick $a_\alpha \in I$ such that $a_\alpha$ is not bounded by any element of $I_\alpha$. Since $I$ is $\delta^+$-directed there exists $a$ above all the $a_\alpha$'s, but then $a \in I_\alpha$ for some $\alpha < \delta$, contradicting the choice of $a_\alpha$. Thus there is $\alpha < \delta$ such that $I_\alpha$ is cofinal in $I$. By renaming, we can assume without loss of generality that $I_0$ is already cofinal in $I$, hence $I_0$ is cofinal in $I$ for all $\alpha < \delta$. Note that $I_0$ must itself be $\lambda^+$-directed.

Now pick $\langle i_j : j < \lambda \rangle$ an increasing sequence in $I_0$ such that $\langle M_{i_j} : j < \lambda \rangle$ is strictly increasing (this is possible by properness of the system). For $k < \lambda$ of cofinality at least $\mu$, let $N_k = \bigcup_{j < k} M_{i_j}$. Note that if $\text{cf}(k) \geq \lambda_\alpha$, then by Fact 2.6 $N_k$ is
not $\alpha$-presentable. Fix $\alpha < \delta$ such that $\lambda_0 < \lambda_\alpha$. We then have that $N^1 := N_{\lambda_\alpha}$ is not $\alpha$-presentable, but $N^2 := M_{\lambda_0}$ is $\lambda_0$-presentable. Since $N^1 \leq K N^2$, this contradicts Lemma 6.2.

We have arrived at the main technical result of this section.

**Theorem 6.6.** Let $K$ be a $\mu$-AEC. If $\lambda > \text{LS}(K)$ is $\mu$-closed, then there are no proper $(\lambda^+, < \lambda^+)$-systems in $K$.

**Proof.** By Lemma 6.4 (with $\lambda^+$ in place of $\lambda$) and Lemma 6.5.

We get that, at least for successors of high-enough $\mu$-closed cardinals (or under SCH, see below), the presentability rank spectrum contains the accessibility spectrum.

**Corollary 6.7.** Let $K$ be a $\mu$-AEC. If $\lambda > \text{LS}(K)$ is a $\mu$-closed cardinal such that $K$ is $\lambda^+$-accessible and $K$ has an object of cardinality at least $\lambda$, then $K$ has an object of presentability rank $\lambda^+$.

**Proof.** Let $M \in K$ have cardinality at least $\lambda$. Using Fact 2.13 together with the assumption that $\lambda$ is $\mu$-closed, $M$ is not $(< \lambda^+)$-presentable. By Theorem 6.6 there are no proper $(\lambda^+, < \lambda^+)$-systems in $K$. By Lemma 6.1 $K$ has an object of presentability rank $\lambda^+$.

We have in particular recovered [LRVa, 4.13]. This will later be further generalized to any accessible category (Theorem 7.11).

**Corollary 6.8.** Let $K$ be a $\mu$-AEC and let $\lambda = \lambda^{< \mu} \geq \text{LS}(K)$. We have that $K$ has an object of presentability rank $\lambda^+$ if at least one of the following conditions hold:

1. $\lambda > \text{LS}(K)$, $\lambda$ is $\mu$-closed, and $K$ has an object of cardinality at least $\lambda$.
2. $\lambda$ is regular and $K$ has an object of cardinality at least $\lambda^+$.

**Proof.** Since $\lambda = \lambda^{< \mu}$, $\lambda^+$ is $\mu$-closed, so by Fact 2.7 $K$ is $\lambda^+$-accessible. Now:

1. This follows from Corollary 6.7
2. Since $K$ has $\mu$-directed colimits, it is also $(\lambda, \lambda^+)$-accessible. Since $K$ has an object of cardinality at least $\lambda^+$ and $\lambda^+$ is $\mu$-closed, Fact 2.13 (with $\lambda^+$ in place of $\lambda$) implies that this object is not $\lambda^+$-presentable. Now apply Fact 2.13.

**Remark 6.9.** The example of well-orderings ordered by initial segment given in [LRVa, 6.2] shows that, even when $\mu = \aleph_0$, we may not have an object of rank $\text{LS}(K)^+$ if $\text{LS}(K)$ is singular.

Under SCH, the statements simplify and we recover [LRVa, 4.15]:

**Corollary 6.10.** Let $K$ be a large $\mu$-AEC. If SCH holds above $\text{LS}(K)$, then for every $\lambda > \text{LS}(K)$ of cofinality at least $\mu$, $K$ has an object of presentability rank $\lambda^+$. In particular, $K$ is weakly LS-accessible.
Proof. By Fact 2.2, $\lambda = \lambda^{\mu}$. If $\lambda$ is regular, we may apply Corollary 6.8(2). If $\lambda$ is singular, then by Fact 2.2 it is $\mu$-closed so one may apply Corollary 6.8(1). □

Still under SCH, we obtain that the (successor) accessibility spectrum is eventually contained in the existence spectrum:

**Corollary 6.11.** Assume ESCH. Let $K$ be a large category with all morphisms monos. For all high-enough successor cardinals $\theta$, if $K$ is $\theta$-accessible, then $K$ has an object of presentability rank $\theta$.

Proof. By Fact 2.12, $K$ is equivalent to a $\mu$-AEC $K$. By replacing $K$ by a tail segment if necessary, we can assume without loss of generality that SCH holds above $\text{LS}(K)$. Pick $\theta > \text{LS}(K)^+$ successor such that $K$ is $\theta$-accessible. Write $\theta = \lambda^+$. If $\text{cf}(\lambda) \geq \mu$, Corollary 6.10 gives the result, so we may assume that $\text{cf}(\lambda) < \mu$. In this case, the SCH assumption implies that $\lambda$ is $\mu$-closed so we can apply Corollary 6.7. □

Recall (Definition 2.10) that a category is LS-accessible if it has objects of all high-enough internal sizes.

**Corollary 6.12.** Assuming ESCH, any large well accessible category with all morphisms monos is LS-accessible.

Note that Corollary 6.12 can be seen as a joint generalization of [LR16, 2.7] (LS-accessibility of large accessible categories with directed colimits and all morphisms monos) and [LRVa, 5.9] (LS-accessibility of large $\mu$-AECs with intersections): in both cases, the categories in question are well accessible with all morphisms monos (see Fact 2.9 [LRVa, 5.4]). Note however that the proof of LS-accessibility of large accessible categories with directed colimits and all morphisms monos does not assume SCH.

### 7. The existence spectrum of an accessible category

A downside of the previous section was the assumption that all morphisms were monos. In the present section, we look at what can be said for arbitrary accessible categories. The main tool is the fact that the inclusion functor $K_{\text{mono}} \to K$ is (in a sense we make precise) accessible, hence plays reasonably well with internal sizes. While the notion of an accessible functor appears already in [MP89, §2.4], we give here a more parameterized definition, in the style of Definition 2.8.

**Definition 7.1.** Let $\lambda$ and $\mu$ be infinite cardinals, with $\mu$ regular. A functor $F : K \to L$ is $(\mu, < \lambda)$-accessible if it preserves $\mu$-directed colimits and both $K$ and $L$ are $(\mu, < \lambda)$-accessible. We say that $F$ is $(\mu, \lambda)$-accessible if $\lambda$ is regular and $F$ is $(\mu, < \lambda^+)$-accessible. We say that $F$ is $\mu$-accessible precisely when it is $(\mu, \mu)$-accessible.

**Fact 7.2** ([LRV19a, 6.2]). If $K$ is a $\mu$-accessible category, there there exists a cardinal $\lambda \geq \mu$ such that $K_{\text{mono}}$ is $(\mu, \lambda)$-accessible and moreover the inclusion functor $F$ of $K_{\text{mono}}$ into $K$ is $(\mu, \lambda)$-accessible.
The following properties, describing the interaction of an accessible functor with presentability, were first systematically investigated in [BR12 §3]:

**Definition 7.3.** A functor $F : \mathcal{K} \to \mathcal{L}$ preserves $\lambda$-presentable objects if whenever $M$ is $\lambda$-presentable in $\mathcal{K}$, then $F(M)$ is $\lambda$-presentable (in $\mathcal{L}$). We say that $F$ reflects $\lambda$-presentable objects if $M$ is $\lambda$-presentable in $\mathcal{K}$ whenever $F(M)$ is $\lambda$-presentable in $\mathcal{L}$. We also say that $F$ preserves $\lambda$-ranked objects if whenever $r_\lambda(M) = \lambda$, then $r_\lambda(FM) = \lambda$. Similarly define what it means for $F$ to reflect $\lambda$-ranked objects.

Of course, there is a simple test to determine when a functor preserves rank given information as to whether it preserves and reflects presentable objects:

**Lemma 7.4.** Let $F : \mathcal{K} \to \mathcal{L}$ be an accessible functor and let $\mu$ be a regular cardinal. If $F$ preserves $\mu$-presentable objects and reflects $(< \mu)$-presentable objects, then $F$ preserves $\mu$-ranked objects. Similarly, if $F$ preserves $(< \mu)$-presentable objects and reflects $\mu$-presentable objects, then $F$ reflects $\mu$-ranked objects.

**Proof.** We prove the first statement (the proof of the second is similar). Let $M$ be an object of $\mathcal{K}$ such that $r(M) = \mu$. Then $r(FM) \leq \mu$ because $F$ preserves $\mu$-presentable objects, and if $r(FM) < \mu$, then $r(M) < \mu$ because $F$ reflects $(< \mu)$-presentable objects, contradiction. Thus $r(M) = r(FM)$. \qed

For a functor to reflect $\lambda$-presentable objects, it enough that it is sufficiently accessible and that the functor reflects split epimorphisms (i.e. if $Ff$ is a split epi, then $f$ is a split epi). This was isolated in [BR12 3.6]. We now proceed to mine the proof of this result to extract what can be said in our more parameterized setup:

**Lemma 7.5.** Let $\lambda$ and $\mu$ be cardinals, $\mu$ regular. Let $F : \mathcal{K} \to \mathcal{L}$ be a functor reflecting split epimorphisms and preserving $\mu$-directed colimits. Let $\langle M_i : i \in I \rangle$ be a $(\mu, < \lambda)$-system with colimit $M$. If $\langle M_i : i \in I \rangle$ is proper, then $\langle FM_i : i \in I \rangle$ is proper. If in addition $F$ preserves $(< \lambda)$-presentable objects, then $\langle FM_i : i \in I \rangle$ is a $(\mu, < \lambda)$-system.

**Proof.** Since $F$ preserves $\mu$-directed colimits, the colimit of $\langle FM_i : i \in I \rangle$ is $FM$. Suppose that the identity map on $FM$ factors through some $FM_i$, via a map $g : FM \to FM_i$. That is, $(Ff_i)g = \text{id}_{FM}$, where $f_i : M_i \to M$ is a colimit map. Then $Ff_i$ is a split epimorphism, hence $f_i$ is a split epimorphism, i.e. $f_i g = \text{id}_{M_i}$, so $\langle M_i : i \in I \rangle$ is not proper. The last sentence is immediate from the definition. \qed

**Fact 7.6 ([BR12 3.6]).** Let $\lambda$ be an uncountable cardinal, and let $F : \mathcal{K} \to \mathcal{L}$ be a functor reflecting split epimorphisms. If there exists a regular cardinal $\lambda_0 < \lambda$ such that $F$ is $(\lambda_0, < \lambda)$-accessible and for all regular cardinals $\mu \in [\lambda_0, \lambda)$, $\mathcal{K}$ is $(\mu, < \lambda)$-accessible, then $F$ reflects $(< \lambda)$-presentable objects.

**Proof.** Assume that $FM$ is $(< \lambda)$-presentable. Pick a regular cardinal $\mu \in [\lambda_0, \lambda)$ such that $FM$ is $\mu$-presentable. By $(\mu, < \lambda)$-accessibility, $M$ is the colimit of a $(\mu, < \lambda)$-system $\langle M_i : i \in I \rangle$. Assume for a contradiction that $M$ is not $(< \lambda)$-presentable. Then $\langle M_i : i \in I \rangle$ must be proper by Fact 2.0.2. By Lemma 7.5 $\langle FM_i : i \in I \rangle$ is proper, hence its colimit $FM$ cannot be $\mu$-presentable by Fact 2.0.2, a contradiction. \qed
In passing, we can deduce the following powerful criterion for existence of an object of regular internal size. Notice that this is a generalization of Fact 2.14 (which is the special case of the identity functor).

**Theorem 7.7.** Let $\lambda$ be a regular cardinal and let $F : \mathcal{K} \to \mathcal{L}$ be a $(\lambda, \lambda^+)$-accessible functor that preserves $\lambda^+$-presentable objects and reflects isomorphisms. If all morphisms in $\mathcal{K}$ are monos and $\mathcal{K}$ has an object that is not $\lambda^+$-presentable, then $\mathcal{L}$ has an object of presentability rank $\lambda^+$.

**Proof.** Since $F$ reflects isomorphisms and all morphisms in $\mathcal{K}$ are monos, $F$ reflects split epimorphisms. By Fact 2.14, $\mathcal{K}$ has a proper $(\lambda, \lambda^+)$-system $\langle M_i : i \in I \rangle$ with $\lambda$-many objects. By Lemma 7.5, $\langle FM_i : i \in I \rangle$ is a proper $(\lambda, \lambda^+)$-system. By Corollary 2.7, the colimit of this system in $\mathcal{L}$ has presentability rank $\lambda^+$. □

To preserve $\lambda$-presentable objects, a cardinal arithmetic assumption on $\lambda$ suffices:

**Fact 7.8.** Let $F : \mathcal{K} \to \mathcal{L}$ be a $(\mu, \lambda_0)$-accessible functor. Let $\lambda_1 \geq \lambda_0$ be a regular cardinal such that the image of any $\lambda_0$-presentable object is $\lambda_1$-presentable. If $\lambda > \lambda_1$ is such that $\lambda^-$ is $\mu$-closed, then $F$ preserves $(< \lambda)$-presentable objects.

**Proof.** Similar to the proof of [AR94, 2.19]. □

We obtain the following cardinal arithmetic test for preservation and reflection of ranks:

**Lemma 7.9.** Let $F : \mathcal{K} \to \mathcal{L}$ be a $(\mu, \lambda_0)$-accessible functor that preserves $\lambda_0$-presentable objects and reflects split epimorphisms.

If $\theta > \lambda_0$ is the successor of a $\mu$-closed cardinal of cofinality at least $\mu$, then $F$ preserves and reflects $\theta$-ranked objects.

**Proof.** Write $\theta = \lambda^+$, with $\lambda$ a $\mu$-closed cardinal of cofinality at least $\mu$. Note that $\lambda^{< \mu} = \lambda$, since it has cofinality at least $\mu$. Thus both $\lambda$ and $\theta$ are $\mu$-closed. This implies that $F$ preserves $\theta$-presentable objects and preserves $(< \theta)$-presentable objects (Fact 7.8). We also have that $F$ reflects $(< \theta)$-presentable objects and $F$ reflects $\theta$-presentable objects (use Facts 2.9 and 7.6). Now apply Lemma 7.4. □

Using Corollary 6.8, we obtain the following existence spectrum result if the domain of the functor is a large $\mu$-AEC:

**Lemma 7.10.** Let $\mathcal{K}$ be a $\mu$-AEC, let $\lambda_0 > \text{LS}(\mathcal{K})$ be regular, and let $F : \mathcal{K} \to \mathcal{L}$ be a $(\mu, \lambda_0)$-accessible functor that preserves $\lambda_0$-presentable objects and reflects isomorphisms. Let $\lambda \geq \lambda_0$ be a $\mu$-closed cardinal of cofinality at least $\mu$. If $\mathcal{K}$ has an object of cardinality at least $\lambda$, then $\mathcal{L}$ has an object of presentability rank $\lambda^+$.

**Proof.** Since all morphisms of $\mathcal{K}$ are monos, $F$ reflects split epimorphisms. Since $\lambda$ is $\mu$-closed and has cofinality at least $\mu$, $\lambda = \lambda^{< \mu}$. By Corollary 6.8, $\mathcal{K}$ has an object $M$ of presentability rank $\lambda^+$. By Lemma 7.9 (where $\theta$ there stand for $\lambda^+$ here), $F$ preserves $\lambda^+$-ranked objects, so $FM$ has presentability rank $\lambda^+$. □

Putting all the results together, we obtain an existence spectrum result for any large accessible category. This extends Corollary 6.8.
Theorem 7.11. Let \( \mathcal{K} \) be a large \( \mu \)-accessible category.

1. For every high-enough regular \( \lambda \) such that \( \lambda = \lambda^{<\mu} \), \( \mathcal{K} \) has an object of presentability rank \( \lambda^+ \).
2. There exists a regular cardinal \( \mu' \) such that for every high-enough \( \mu' \)-closed cardinal \( \lambda \) of cofinality at least \( \mu' \), \( \mathcal{K} \) has an object of presentability rank \( \lambda^+ \).

Proof. 

1. By Fact 7.2, there exists a cardinal \( \lambda_0 \) such that the inclusion functor \( F \) of \( \mathcal{K}_{\text{mono}} \) into \( \mathcal{K} \) is \( (\mu, \lambda_0) \)-accessible. Of course, \( F \) also reflects isomorphisms. Let \( \lambda > \lambda_0 \) be regular such that \( \lambda = \lambda^{<\mu} \). By Fact 7.8 \( F \) preserves \( \lambda^+ \)-presentable objects and by Fact 2.9 \( F \) is \( (\lambda, \lambda^+) \)-accessible. Since \( \mathcal{K} \) is large, \( \mathcal{K}_{\text{mono}} \) is also large, so by Theorem 7.4 \( \mathcal{K} \) has an object of presentability rank \( \lambda^+ \).
2. As before, \( \mathcal{K}_{\text{mono}} \) is an accessible category with all morphisms monos, so by Fact 7.7 it is equivalent to a \( \mu' \)-AEC \( \mathcal{K}^* \), for some regular cardinal \( \mu' \). Let \( F : \mathcal{K}^* \to \mathcal{K} \) be the composition of the equivalence with the inclusion of \( \mathcal{K}_{\text{mono}} \) into \( \mathcal{K} \). Then \( F \) is \( (\mu', \lambda_0) \)-accessible, for some regular cardinal \( \lambda_0 > \text{LS}(\mathcal{K}) \), and \( F \) reflects isomorphisms. Taking \( \lambda_0 \) bigger if needed (and using Fact 7.8), we can assume without loss of generality that \( F \) also preserves \( \lambda_0 \)-presentable objects. Let \( \lambda \geq \lambda_0 \) be a \( \mu' \)-closed cardinal of cofinality at least \( \mu' \). Since \( \mathcal{K} \) is large, Lemma 7.10 applies and so \( \mathcal{L} \) has an object of presentability rank \( \lambda^+ \).

We obtain the main result of this section. This extends for example [LRVa, A.2] — weak LS-accessibility of large locally multipresentable categories — at the cost of ESCH:

Corollary 7.12. Assuming ESCH, any large accessible category has objects of all internal sizes of high-enough cofinality. In particular, any large accessible category is weakly LS-accessible.

Proof. Let \( \mathcal{K} \) be a large \( \mu \)-accessible category, and let \( \mu' \) be as given by Theorem 7.11. Let \( \lambda \) be a high-enough cardinal of cofinality at least \( \mu' \) (the proof will give how big we need to take it). If \( \lambda \) is a regular cardinal, then (by ESCH, see Fact 2.2) \( \lambda = \lambda^{<\mu} \), so by Theorem 7.11 \( \mathcal{K} \) has an object of presentability rank \( \lambda^+ \). Assume now that \( \lambda \) is a singular cardinal. Then \( \lambda \) is in particular a limit cardinal, so (by ESCH) \( \lambda \) is \( \mu' \)-closed. By Theorem 7.11 \( \mathcal{K} \) has an object of presentability rank \( \lambda^+ \).

8. Filtrations

We consider conditions under which, in a general category, we can ensure that any object is not merely the colimit of an appropriately directed system of objects of strictly smaller internal size, but rather the colimit of a chain of such objects. The existence of such filtrations (sometimes also called resolutions) is crucial to a host
of model-theoretic constructions, and should be of considerable use in the further development of classification theory at the present level of generality.

**Definition 8.1.** For $\mu$ a regular cardinal and $\lambda$ an infinite cardinal, a $(\mu, < \lambda)$-chain (in a category $\mathcal{K}$) is a diagram $\langle M_i : i < \mu \rangle$ indexed by $\mu$, all of whose objects are $(< \lambda)$-presentable. We call $\mu$ the length of the chain. A $(< \lambda)$-chain is a $(\mu, < \lambda)$-chain for some regular $\mu < \lambda$. For $\lambda$ a regular cardinal, a $\lambda$-chain is a $(< \lambda^+)$-chain.

For $\theta$ a regular cardinal, we say that a chain $\langle M_i : i < \mu \rangle$ is $\theta$-smooth if for every $i < \mu$ of cofinality at least $\theta$, $M_i$ is the colimit of $\langle M_j : j < i \rangle$.

Note that $(\mu, < \lambda)$-chains are $(\mu, < \lambda)$-systems in the sense of Definition 2.5. We will use the terminology of systems introduced in the preliminaries. The reader may also wonder why we are looking only at chains indexed by a regular cardinal. This is because any system $\langle M_i : i \in I \rangle$ indexed by a linear order $I$ has a cofinal subsystem of the form $\langle M_{i_j} : i_j < \mu \rangle$, where $\mu$ is the cofinality of $I$.

The next definition is the object of study of this section:

**Definition 8.2.** Let $\mathcal{K}$ be a category. A filtration of an object $M$ is a $(< r_{\mathcal{K}}(M))$-chain with colimit $M$. We call $M$ filtrable if it (has a presentability rank and) has a filtration.

Observe that the length of a filtration is determined by the presentability rank:

**Lemma 8.3.** Let $\lambda$ be a regular cardinal and let $\mathcal{K}$ be a category. If there exists a $(< \lambda)$-chain whose colimit is not $(< \lambda)$-presentable, then $\lambda$ is a successor and the chain must have length $\text{cf}(\lambda^-)$. In particular, any filtrable object $M$ has successor presentability rank and any of its filtrations will have length $\text{cf}(|M|_{\mathcal{K}})$.

**Proof.** Let $\mu < \lambda$ be a regular cardinal and let $\langle M_i : i < \mu \rangle$ be a $(\mu, < \lambda)$-chain in $\mathcal{K}$ with a colimit $M$ that is not $(< \lambda)$-presentable. By Fact 2.6(1), the chain is proper. Next, assume for a contradiction that $\lambda$ is weakly inaccessible. By Fact 2.6(2), $M$ is $(< \lambda)$-presentable, a contradiction to the fact that it has presentability rank $\lambda$. This shows that $\lambda$ is a successor. Let $\lambda_0 = \lambda^-$. We now have to see that $\text{cf}(\lambda_0) = \mu$. We consider two cases depending on whether $\lambda_0$ is regular or singular:

- If $\lambda_0$ is regular, then $\langle M_i : i < \mu \rangle$ is a $(\mu, \lambda_0)$-system. Since $\mu < \lambda$, we know that $\mu \leq \lambda_0$. If $\mu < \lambda_0$, then by Fact 2.6(1), $M$ would be $(\mu^+ + \lambda_0)$-presentable, hence $\lambda_0$-presentable, contradicting that it has presentability rank $\lambda$. Thus $\mu = \lambda_0 = \text{cf}(\lambda_0)$.
- If $\lambda_0$ is singular, then $\langle M_i : i < \mu \rangle$ is a $(\mu, < \lambda_0)$-system, and moreover (because $\mu$ is regular) $\mu \neq \lambda_0$, so $\mu^+ < \lambda_0$. If $\text{cf}(\lambda_0) > \mu$, then there exists a regular $\lambda_1 < \lambda_0$ such that $\langle M_i : i < \mu \rangle$ is a $(\mu, \lambda_1)$-system. By Fact 2.6(1), $M$ is $(\mu^+ + \lambda_1)$-presentable, hence $(< \lambda)$-presentable, a contradiction.

Thus $\text{cf}(\lambda_0) \leq \mu$. If $\text{cf}(\lambda_0) < \mu$, let $\langle \theta_\alpha : \alpha < \text{cf}(\lambda_0) \rangle$ be an increasing chain of regular cardinals cofinal in $\lambda_0$. For all $i < \mu$, there exists $\alpha = \alpha_i < \text{cf}(\lambda_0)$ such that $M_i$ is $\theta_\alpha$-presentable. By cardinality consideration, there must exist $I \subseteq \mu$ of cardinality $\mu$ and $\alpha < \text{cf}(\lambda_0)$ such that for all $i \in I$, $M_i$ is $\theta_\alpha$-presentable. Since $\mu$ is regular, $I$ is cofinal in $\mu$, so $M$ is still the colimit of $\langle M_i : i \in I \rangle$. The latter system is a $(\mu, \theta_\alpha)$-system, hence...
(again by Fact 2.6(1)) $M$ is $(\mu^+ + \theta, \alpha)$-presentable, so $(\prec \lambda)$-presentable, a contradiction. The only remaining possibility is that $\text{cf}(\lambda_0) = \mu$, which is what we wanted to prove.

\[\Box\]

It follows that if the category has directed colimits, we can take the filtration to be smooth. More generally:

**Lemma 8.4.** Any filtration of an object $M$ of presentability rank $\lambda$ is boundedly $(\prec \lambda)$-presentable (Definition 6.3). In particular, if $\theta < \lambda$ is regular such that $K$ has $\theta$-directed colimits, then $M$ has a $\theta$-smooth filtration.

**Proof.** Let $\mu < \lambda$ be regular, and let $\langle M_i : i < \mu \rangle$ be a $(\prec \lambda)$-chain whose colimit is $M$. By Lemma 8.3, $\lambda$ is a successor cardinal and $\mu = \text{cf}(\lambda^-)$. Let $\delta < \mu$ be a limit ordinal. We will show that the colimit of $\langle M_i : i < \delta \rangle$ (assuming it exists) is $(\prec \lambda)$-presentable. The “in particular” part will then follow, since, when $\text{cf}(\delta) \geq \theta$, it suffices to replace $M_\delta$ by the colimit of $\langle M_i : i < \delta \rangle$.

Note that $\delta < \mu \leq \lambda^-$, so $\delta^+ < \lambda$. By cofinality considerations, there exists a regular cardinal $\lambda_0 < \lambda$ such that for all $i < \delta$, $M_i$ is $\lambda_0$-presentable. By Fact 2.6(1), we get that the colimit of $\langle M_i : i < \delta \rangle$ is $(\delta^+ + \lambda_0)$-presentable, hence $(\prec \lambda)$-presentable, as desired.

\[\Box\]

Using the definition of presentability, it is also easy to generalize the well known facts that, for objects of regular cardinality (that is, of presentability rank the successor of a regular cardinal), any two smooth filtrations are the same on a club: a closed unbounded set of indices. See for example [BGL+16, 6.11].

We give a name to categories where every object of a given presentability rank is filtrable:

**Definition 8.5.** For a regular cardinal $\lambda$, we say an accessible category $K$ is $\lambda$-filtrable if any object of presentability rank $\lambda$ is filtrable. For a regular cardinal $\mu$, we say that $K$ is well $\mu$-filtrable if it is $\lambda$-filtrable for any regular $\lambda \geq \mu$. We say $K$ is well filtrable if it is well $\mu$-filtrable for some regular cardinal $\mu$.

Similarly, we say that $K$ is almost $\lambda$-filtrable if any object $M$ of presentability rank $\lambda$ is a retract of a filtrable $\lambda$-presentable object $N$ (i.e. there exists a split epimorphisms from $N$ to $M$). Define almost well $\lambda$-filtrable and almost well filtrable as expected.

**Remark 8.6.** The technical notion of being almost filtrable is included here because we do not know whether retracts of filtrable objects are filtrable. Of course, in categories where all morphisms are monos, retracts are just isomorphisms and so this technical distinction is irrelevant.

In the rest of this section, we give a a couple of easy examples. In the next section, we will use these examples to prove that any accessible category with directed colimits is almost well filtrable.

**Lemma 8.7.** Let $K$ be a $\mu$-AEC and let $M \in K$. If $|UM| > \text{LS}(K)$ and $|UM|$ is $\mu$-closed, then $M$ is filtrable. In particular, $K$ is $\theta$-filtrable for any $\theta > \text{LS}(K)^+$ that is the successor of a $\mu$-closed cardinal of cofinality at least $\mu$. 

Proof. Let $\lambda := |UM|$, and let $\delta := \text{cf}(\lambda)$. Using the cofinality assumption, find $\langle A_i : i < \delta \rangle$ an increasing continuous chain of subsets of $UM$ such that $|A_i| < \lambda$ for all $i < \delta$ and $UM = \bigcup_{i<\delta} A_i$. Using the Löwenheim-Skolem-Tarski axiom, build $\langle M_i : i < \delta \rangle$ increasing in $K$ such that for all $i < \delta$, $A_i \subseteq UM, M_i \subseteq K M$, and $|UM_i| < \lambda$. This is possible: assume $i < \delta$ and we are given $\langle M_j : j < i \rangle$. Let $A := A_i \cup \bigcup_{j<i} UM_j$. By cofinality considerations, $|A| < \lambda$. Since $\lambda$ is $\mu$-closed, there exists $M_i \subseteq K M$ with $|UM_i| < \lambda$ and $A \subseteq UM_i$. This completes the construction. We then have that $M = \bigcup_{i<\lambda} M_i$, and by Fact 2.13 $M$ has presentability rank $\lambda^+$ while each $M_i$ is $(< \lambda^+)$-presentable.

For the “in particular” part, let $\theta > \text{LS}(K)^+$ be the successor of a $\mu$-closed cardinal $\lambda$ of cofinality at least $\mu$. Then $\lambda = \lambda^{<\mu}$ so $\theta$ is also $\mu$-closed. Thus (by Fact 2.13) an object of $K$ is $\theta$-presentable if and only if it has cardinality $\lambda$, and the result follows.

We have in particular derived the following fact, well-known when stated in terms of cardinalities:

**Theorem 8.8.** Any AEC $K$ is well $\text{LS}(K)^{++}$-filtrable.

**Proof.** By Facts 2.12 and 2.9 $K$ is well $\text{LS}(K)^+$-accessible. By Corollary 5.4 presentability ranks greater than $\text{LS}(K)^+$ must be successors. Now apply Lemma 8.7 with $\mu = \aleph_0$. □

**Corollary 8.9.** Any finitely accessible category with all morphisms monos is well filtrable.

**Proof.** By Fact 2.12 such a category is equivalent to an AEC, so this is a special case of Theorem 8.8. □

Using the tools of Section 7 we can also obtain a result for any accessible category:

**Corollary 8.10.** For any accessible category $K$, there exists a regular cardinal $\mu$ such that for all high-enough $\mu$-closed cardinals $\lambda$ of cofinality at least $\mu$, $K$ is $\lambda^+$-filtrable. In particular, assuming ESCH, $K$ is filtrable in any cardinal that is the successor of a limit cardinal of high-enough cofinality, or the double successor of any cardinal of high-enough cofinality.

**Proof.** Similar to the proof of Theorem 7.11 and Corollary 7.12 using Lemma 8.7. □

The next result will not be needed later, and uses some material from [LRVA] on $\mu$-AECs with intersections (i.e. with a well-behaved closure operator). There, the internal size is just the minimal size of a generator, and the existence of filtrations follows immediately.

**Theorem 8.11.** Any $\mu$-AEC with intersections is well $\mu^+$-filtrable.

**Proof.** Let $K$ be a $\mu$-AEC, let $\lambda \geq \mu^+$ be a regular cardinal and let $M \in K$ have presentability rank $\lambda$. By [LRVA] 5.7, pick $A \subseteq UM$ such that $M = \text{cl}^M(A)$ and $|A|^+ = \lambda$. Let $\delta := \text{cf}(|A|)$, and write $A = \bigcup_{i<\delta} A_i$, where $|A_i| < |A|$ and...
$A_i \subseteq A_j$ for $i < j < \delta$. Let $M_i := cl^M(A_i)$. By [LRVa] 5.7 again, each $M_i$ is $(<\lambda)$-presentable, as desired. □

9. Filtrations and reflections

In this section, we investigate filtrations in accessible categories with directed colimits. The goal is to prove that these categories are well filtrable. One result in this direction is the second author’s [Ros97, Lemma 1], which establishes that such categories are filtrable at successors of regular cardinals:

**Fact 9.1.** For a regular cardinal $\lambda$, any $\lambda$-accessible category with directed colimits is $\lambda^+$-filtrable.

The case of successors of singular cardinals seems much harder, but we succeed in proving it for finitely accessible categories (Corollary 9.11). For accessible categories with directed colimits, we prove only that they are almost well filtrable (Corollary 9.12). In each case, the argument relies on embedding such categories as reflective subcategories of nice categories of the kind considered at the end of the previous section, and pulling the filtration back along the reflection functor. Before proceeding, we recall:

**Definition 9.2.** A full subcategory $K^*$ of a category $K$ is reflective if the inclusion functor $i : K^* \to K$ has a left adjoint $F : K \to K^*$. In this case, we call $F$ the reflection functor, or reflector.

Note that we assume reflective subcategories are full, as is now more or less customary. We will assume, too, that the reflector is the identity when restricted to the reflective subcategory.

**Example 9.3.** The category of complete metric spaces is a reflective subcategory of the category of all metric spaces: the reflector takes each metric space to its completion.

**Lemma 9.4.** Suppose $\mathcal{K}^*$ is a reflective subcategory of $\mathcal{K}$, with reflector $F$. If $\langle M_i : i \in I \rangle$ is a diagram in $\mathcal{K}$, then, whenever both colimits exist:

$$F(\text{colim}^\mathcal{K} M_i) \cong \text{colim}^\mathcal{K}^* F(M_i)$$

**Proof.** Since $F$ is a left adjoint, it preserves arbitrary colimits. □

**Definition 9.5.** Let $\mathcal{K}^*$ be a reflective subcategory of $\mathcal{K}$, with reflector $F$. For an object $M$ of $\mathcal{K}^*$, let $r_F(M)$ be the minimal regular cardinal $\lambda$ such that there is $M_0 \in \mathcal{K}$ so that $M$ is a retract of $F(M_0)$ and $M_0$ is $\lambda$-presentable in $\mathcal{K}$.

In the case of Example 9.3 above, where the reflector $F$ corresponds to metric completion, $r_F$ will give the successor of the density character. This generalizes to:

**Lemma 9.6.** Let $\lambda$ be a regular cardinal. Assume $\mathcal{K}$ is $\lambda$-accessible and $\mathcal{K}^*$ is a reflective subcategory closed under $\lambda$-directed colimits inside $\mathcal{K}$. Let $M$ be an object of $\mathcal{K}^*$.

1. If $M$ is $\lambda$-presentable in $\mathcal{K}$, then $r_F(M) \leq \lambda$. 

Lemma 9.7. Let \( r_F(M) \leq \lambda \), then \( M \) is \( \lambda \)-presentable in \( \mathcal{K}^* \).
(3) If \( M \) is \( \lambda \)-presentable in \( \mathcal{K}^* \), then \( r_F(M) \leq \lambda \).

Proof.
(1) Notice that \( M = F(M) \), as we assume \( F \) to be the identity on \( \mathcal{K}^* \).
(2) By diagram chase.
(3) Resolve \( M \) as a \( \lambda \)-directed colimit of \( \lambda \)-presentable objects \( M_i \) in \( \mathcal{K} \). Since \( M = F(M) \), \( M \) is the \( \lambda \)-directed colimit of the \( F(M_i) \)'s in \( \mathcal{K}^* \). Since each \( M_i \) is \( \lambda \)-presentable in \( \mathcal{K} \), \( r_F(F(M_i)) \leq \lambda \), so \( F(M_i) \) is \( \lambda \)-presentable in \( \mathcal{K}^* \). Since \( M \) is \( \lambda \)-presentable in \( \mathcal{K}^* \), it is a retract of some \( F(M_i) \), as desired.

Lemma 9.8. Let \( \mu \) be a regular cardinal, let \( \mathcal{K} \) be a well \( \mu \)-accessible category, let \( \mathcal{K}^* \) be a reflective subcategory of \( \mathcal{K} \) closed under \( \mu \)-directed colimits inside \( \mathcal{K} \), and let \( F \) be a reflector. If \( M \) is an object of \( \mathcal{K}^* \) that is not \((< \mu)\)-presentable in \( \mathcal{K}^* \), then \( r_{\mathcal{K}^*}(M) = r_F(M) \).

Proof. Let \( \lambda := r_{\mathcal{K}^*}(M) \). We know that \( \lambda \geq \mu \), since \( M \) is not \((< \mu)\)-presentable. By Lemma 9.6(3), \( r_F(M) \leq \lambda \). Let \( \lambda_0 \in [\mu, \lambda] \) be a regular cardinal. By Lemma 9.6(2), if \( r_F(M) \leq \lambda_0 \), then \( M \) would be \( \lambda_0 \)-presentable in \( \mathcal{K}^* \), and hence \( r_{\mathcal{K}^*}(M) \leq \lambda_0 \). This is only possible for \( \lambda_0 = \lambda \), hence \( r_F(M) = \lambda \).

Fact 9.8 ([BR12, 4.5]). If \( \mathcal{K}^* \) is a \((\mu, \lambda)\)-accessible category, then \( \mathcal{K}^* \) is a reflective subcategory of a \( \mu \)-accessible category \( \mathcal{K} \), and \( \mathcal{K}^* \) is closed under \( \lambda \)-directed colimits inside \( \mathcal{K} \).

We can now generalize our results on filtrations. The key lemma shows that if a reflective subcategory is well filtrable, then the bigger category is (almost) well filtrable.

Lemma 9.9. Let \( \mu < \lambda \) be regular cardinals, and let \( \mathcal{K}^* \) be a well \( \mu \)-accessible category, which is a reflective subcategory of a well \( \lambda \)-filtrable category \( \mathcal{K} \), and further is closed under \( \mu \)-directed colimits inside \( \mathcal{K} \). Then \( \mathcal{K}^* \) is almost well \( \lambda \)-filtrable.

Proof. Let \( \theta \geq \lambda \) be a regular cardinal. Let \( M \) be an object of \( \mathcal{K}^* \) of presentability rank \( \theta \). By Lemma 9.7, there is \( M^* \) which is \( \theta \)-presentable in \( \mathcal{K} \) and so that \( M \) is a retract of \( F(M^*) \). Since \( \mathcal{K} \) is \( \theta \)-filtrable, one can pick a filtration \( \langle M^*_i : i < \delta \rangle \) of \( M^* \) in \( \mathcal{K} \). Now let \( M_i := F(M^*_i) \). Then (by definition of \( r_F \)), \( r_F(M_i) < \lambda \), so by Lemma 9.7 \( M_i \) is \((< \lambda)\)-presentable in \( \mathcal{K}^* \). Furthermore, \( \langle M_i : i < \delta \rangle \) form a chain in \( \mathcal{K}^* \), and (still in \( \mathcal{K}^* \)) \( F(M^*) \) is the colimit of this chain (Lemma 9.4).

Theorem 9.10. Any accessible category with directed colimits and all morphisms monos is well filtrable.

Proof. Let \( \mathcal{K}^* \) be a \( \mu \)-accessible category with directed colimits and all morphisms monos. By Fact 9.8 there exists a finitely accessible category \( \mathcal{K} \) so that \( \mathcal{K}^* \) is a reflective full subcategory of \( \mathcal{K} \), closed under \( \mu \)-directed colimits inside \( \mathcal{K} \). We know that all the morphisms in \( \mathcal{K} \) are monos, so by Corollary 8.9 \( \mathcal{K} \) is well filtrable. By Fact 2.9, \( \mathcal{K}^* \) is well \( \mu \)-accessible. By Lemma 9.9 we deduce that \( \mathcal{K}^* \) is almost
well filtrable, but since all morphisms in $K^*$ are monos, split epimorphisms are just isomorphism, so $K^*$ is in fact well filtrable.

\[\square\]

\begin{corollary}
\label{corollary:9.11}
Any finitely accessible category is well filtrable.
\end{corollary}

\begin{proof}
Let $K$ be a finitely accessible category. Then $K_{\text{mono}}$ is an accessible category with directed colimits and all morphisms monos (Fact 7.2). By Theorem 9.10 $K_{\text{mono}}$ is well filtrable. Moreover the embedding of $K_{\text{mono}}$ into $K$ preserves directed colimits (Fact 7.2) and reflects split epimorphisms. Thus (Facts 7.6, 7.8), this embedding preserves and reflects presentability ranks starting at some cardinal. It immediately follows that $K$ itself is well filtrable.
\end{proof}

\begin{corollary}
\label{corollary:9.12}
Any accessible category with directed colimits is almost well filtrable.
\end{corollary}

\begin{proof}
Imitate the proof of Theorem 9.10: any accessible category with directed colimits is a reflective subcategory of a finitely accessible category, which is well filtrable by Corollary 9.11.
\end{proof}
