Mid-Infrared Electro-Optical Modulation Using Monolithically Integrated Titanium Dioxide on Lithium Niobate Optical Waveguides

Tiening Jin1, Junchao Zhou1 & Pao Tai Lin1,2*

Tunable photonic circuits were demonstrated in the mid-Infrared (mid-IR) regime using integrated TiO2-on-LiNbO3 (ToL) waveguides. The upper waveguide ridge was made by a sputtered TiO2 thin film with broad transparency at λ = 0.4–8 µm and an optimized refractive index n = 2.39. The waveguide substrate is a z-cut single crystalline LiNbO3 (LN) wafer that has strong Pockels effect, thus enabling the tunability of the device through electro-optical (E-O) modulation. A sharp waveguide mode was obtained at λ = 2.5 µm without scattering or mode distortion found. The measured E-O coefficient γeff was 5.9 pm/V approaching γ31 of 8.6 pm/V of LN. The ToL waveguide showed a hybrid mode profile where its optical field can be modified by adjusting the TiO2 ridge height. Our monolithically integrated ToL modulator is an efficient and small footprint optical switch critical for the development of reconfigurable photonic chips.

Mid-IR photonic circuits have attracted a lot of attention because of their application in broadband optical communication and label-free biochemical sensing1–3. For the optical network, extending the present operational spectrum from the near-IR into the mid-IR region provides additional optical channels thus improving the data transmission rates4. Specifically, E-O devices capable of fast intensity modulation are essential components for high bit rate optical communication and information processing5. Previous works in mid-IR photonic circuits have been demonstrated in various silicon-based platforms, such as Si-on-insulator, Si-on-sapphire, Si-on-AlN, and pedestal Si6,7. However, silicon has low optical nonlinearity (χ3) and absence of E-O tunability from Pockels and Kerr effects that limit its application for nonlinear frequency conversion and high-speed optical signal modulation8. In addition, the present Si photonics platform utilizes SiO2 as the optical waveguide undercladding, while SiO2 becomes opaque at λ > 4.0 µm9. Thus, Si-on-insulator was unsuitable for broadband mid-IR applications.

Another material option to achieve reconfigurable mid-IR photonics is lithium niobate, a ferroelectric and high nonlinear optical crystal10,11. First, LN is transparent up to λ > 5 µm with a moderate refractive index, n = 2.1812, which grants it versatile roles either as a waveguide cladding or a waveguide core in the mid-IR regime13,14. Second, LN has a high E-O coefficient and a large second-order optical nonlinearity (χ2) so it enables efficient nonlinear light generation and E-O light modulation15,16. Previous studies have shown a LN switch in Near-Infrared (NIR) with a modulation speed exceeding 100 GHz17 and a low Vπ∙L of ~10 Vcm18, where Vπ∙L is the product of the voltage and the device length to create a π phase difference. In addition, both phase and intensity LN modulators can achieve a high extinction ratio >15 dB, which is significantly better than present Si based photonic devices19. Therefore, LN is an ideal platform for tunable mid-IR photonic circuits.

In this work, we created reconfigurable waveguides that monolithically integrated ferroelectric LN and mid-IR transparent TiO2. From finite difference method (FDM) modeling, the ToL photonic circuits had a hybrid waveguide mode, where its optical field confined in the LN and the TiO2 layers can be optimized by the TiO2 thickness. Unlike the Si-on-LN waveguide that had its optical field dominantly confined in the high refractive index Si, our
The ToL device was able to confine majority of the lightwave in the ferroelectric LN layer, which is critical to achieve efficient E-O modulation. This is because TiO$_2$ and LN have a lower refractive index contrast, $\Delta n = 0.21$, compared to a $\Delta n = 1.3$ between Si and LN. The ToL waveguide structures were characterized by a scanning electron microscope (SEM) equipped with energy-dispersive X-ray spectroscopy (EDS). Meanwhile, the effective E-O coefficient in mid-IR regime was obtained by measuring the mode intensity variation when an external electrical field $E$ was applied across the waveguide. Hence, the developed ToL platform enables reconfigurable mid-IR photonic circuits desired for broadband optical communication.

**Experimental Methods**

The detailed device fabrication process is shown in Fig. 1a. First, a negative tone photoresist was patterned on a LN wafer, which defined the waveguide structure. After development, the photoresist had undercut sidewall that will facilitate the lift-off process. Next, a 0.8$\mu$m thick TiO$_2$ film was deposited on the patterned substrate by room temperature RF sputtering. The target was Ti (99.999%) and the gases introduced into the deposition chamber were 36 sccm argon and 4 sccm oxygen. After TiO$_2$ deposition, the photoresist and the TiO$_2$ above were removed by acetone and only the TiO$_2$ ridge waveguide was left on the LN substrate. Applying the same lithography and lift-off steps, 100 nm thick Ti electrodes were deposited on both sides of the TiO$_2$ waveguide. The ToL fabrication avoided delicate and costly processes including ion slicing and wafer bonding utilized in prior LN thin film devices.$^{20,21}$

The waveguide optical property and the E-O reconfigurability of the ToL were characterized by a testing station shown in Fig. 1b. The light source was a pulsed laser with a wavelength tunable from $\lambda = 2.4$ to $3.8\mu$m and a linewidth of 3cm$^{-1}$. It had a 150 kHz pulse repetition rate, 10 nano seconds pulse duration, and 150 mW average power. The probe laser light was first focused into a 9$\mu$m core fluoride fiber using a reflective lens, and then butt-coupled into the waveguide. The fine alignment between the optical fiber and the ToL waveguide was monitored by an upper microscope equipped with a long working distance 10x objective lens. The light emitted from the waveguide back facet was focused by a CaF$_2$ biconvex lens with 25 mm focal length and then captured by a liquid nitrogen cooled 640 $\times$ 512 pixel InSb camera. A polarizer was placed before the camera, selecting the polarization of the recorded light signal. Meanwhile, an electric field $E$ was applied across the ToL waveguide using the pair of Ti electrodes that were loaded on the two sides of the TiO$_2$ ridge. The electrodes were connected with a DC power supply through two micro-manipulators. $E$ was determined by the applied voltage, $V$, of the power supply and the gap width, $g$, between the pair of electrodes. The waveguide mode intensity was then recorded when the $V$ was swept between 0 and 100 V.
Results and Discussion

The waveguide mode was numerically simulated by the two-dimensional FDM. In the modeling, a 12 μm × 6 μm TM light source was chosen to excite a mode at λ = 2.5 μm since its dimension is close to the 9 μm core mid-IR fiber used in the experiment. The refractive indexes, n, of TiO₂ and LN are 2.39 and 2.18, respectively.22,23 The mode profile and field intensity confined in the TiO₂ and LN layers were modified by adjusting the TiO₂ thickness, T_{TiO₂}. As shown in Fig. 2a at T_{TiO₂} = 1 μm, a fundamental mode was clearly observed within the TiO₂ ridge while a strong evanescent field appeared in the LN cladding layer, which was a characteristic profile belonging to the TM polarization mode.24 As T_{TiO₂} decreased to 0.8 μm, the mode center shifted toward the LN layer. A hybrid mode with a strong field existing in both LN and TiO₂ layers was revealed. A TiO₂ waveguide with this configuration is capable of efficient E-O modulation, since the optical field was confined in the ferroelectric LN layer and its overlapping with the electric field significantly increased. As T_{TiO₂} decreased to 0.6 μm, no TM waveguide mode was found because the TiO₂ layer was too thin to support a TM mode. To better visualize the variation of the optical field when T_{TiO₂} changed, Fig. 2b shows the calculated 1-D intensity profiles parallel to the z direction at y = 0 μm. At T_{TiO₂} = 1 μm, the intensity peak appeared in the center of the TiO₂ layer, while the evanescent field in the lower LN cladding was much stronger than in upper air cladding since the LN has a higher refractive index than air. At T_{TiO₂} = 0.8 μm, a hybrid mode was formed and the optical field in the ferroelectric LN layer became stronger, which was critical to achieve low Vπ·L E-O modulation. On the other hand, at T_{TiO₂} = 0.6 μm, there was no light confinement along the z direction. The TM waveguide mode disappeared since the TiO₂ layer was too thin.
The one-dimensional intensity distribution at different polarizations is drawn in Fig. 5b. The obtained Gaussian-like mode profile is similar to the hybrid mode resolved at Fig. 2b. Figure 5c shows the plot of mode intensity versus polarization angle $\Theta$.

### Table 1.
The ToL waveguide’s optical field distribution factors, $\Gamma_{\text{LN}}$, $\Gamma_{\text{TiO}_2}$, and $\Gamma_{\text{Air}}$, at different thickness $T_{\text{TiO}_2}$. $\Gamma_{\text{LN}}$ increased from 46.0 to 80.0 as $T_{\text{TiO}_2}$ decreased from 1.0 to 0.6 $\mu$m indicating an improvement of E-O modulation efficient.

| $T_{\text{TiO}_2}$ ($\mu$m) | $\Gamma_{\text{LN}}$ (%) | $\Gamma_{\text{TiO}_2}$ (%) | $\Gamma_{\text{Air}}$ (%) |
|--------------------------|-------------------------|---------------------------|-------------------------|
| 1.0                      | 46.0                    | 47.4                      | 6.6                     |
| 0.8                      | 62.3                    | 31.5                      | 6.2                     |
| 0.6                      | 80.0                    | 15.5                      | 4.5                     |

thin. The optical field distribution factors, $\Gamma_{\text{LN}}$, $\Gamma_{\text{TiO}_2}$, were defined as the percentages of optical fields found within the LN and the TiO$_2$ layers, respectively. As shown in Table 1 and Fig. 2c, $\Gamma_{\text{LN}}$ increased rapidly from 46.0% to 80.0% while $\Gamma_{\text{TiO}_2}$ decreased from 47.4% to 15.5%, as $T_{\text{TiO}_2}$ decreased from 1.0 to 0.6 $\mu$m. The optimized $T_{\text{TiO}_2}$ was 0.80 $\mu$m since it had a large $\Gamma_{\text{LN}}$ and also a sufficient thickness to support the TM waveguide mode. Therefore, optimization of $T_{\text{TiO}_2}$ reshaped the intensity distribution of the waveguide mode, leading to a stronger optical field confined within the LN layer. Consequently, this enhanced the interaction between the mid-IR light wave and the electrical field that created high E-O reconfigurability and reduced optical propagation loss.

The optical property of deposited TiO$_2$ thin film was characterized by attenuated total reflection - Fourier transform infrared spectroscopy (ATR-FTIR) and the result is displayed in Fig. 3. High transmittance was found over a broad mid-IR spectrum between $\lambda = 2.5$ to 8.0 $\mu$m. The strong absorption after $\lambda = 8.0 \mu$m is due to the combinations of fundamental vibration modes existing at longer wavelengths, such as the Ti-O stretching and bending vibrations. The results showed that the sputtered TiO$_2$ thin film is a suitable material for mid-IR photonic circuits.

The structure of ToL device was inspected by a SEM equipped with EDS. Figure 4a shows the cross-sectional SEM image of a 10 $\mu$m wide and 0.8 $\mu$m height TiO$_2$ ridge waveguide sitting on a LN substrate. Two Ti electrodes were loaded on each side of the waveguide. The device has a well-defined ridge structure without cracks or indents on the surface. The sharp waveguide edges reduced the waveguide propagation loss caused by light scattering. In addition, the interface between the TiO$_2$ waveguide and LN layer was well-resolved. No depletion damage was found on the device surfaces or the interface because the waveguide was prepared by a lift-off process instead of an aggressive etching process. EDS with element mapping function was utilized to characterize the device layout and the material composition. As shown in Fig. 4b, the Ti profile identified the TiO$_2$ ridge waveguide in the ToL center and two thin Ti electrodes loaded next to the waveguide. In Fig. 4c, the Nb distribution corresponded to the LN substrate that was underneath the TiO$_2$ waveguide and Ti electrodes. The well-defined waveguide configuration and the high material uniformity avoided the optical loss caused by refractive indexes.

Figure 5a shows the optical waveguide mode at $T_{\text{TiO}_2} = 0.80 \mu$m and its transmission at different polarizations. A sharp waveguide mode was clearly observed at $\lambda = 2.5 \mu$m when the polarization angle $\Theta$ at 0° was parallel to the laser TM polarization. No scattering and distortion found in the captured images indicates that our waveguide has flat sidewalls and a smooth interface between the TiO$_2$ and LN layer. As the $\Theta$ rotated from 0° to 90°, the mode intensity dropped sharply indicating the ToL had a waveguide mode with TM polarization. The one-dimensional intensity distribution at different polarizations is drawn in Fig. 5b. The obtained Gaussian-like mode profile is similar to the hybrid mode resolved at Fig. 2b. Figure 5c shows the plot of mode intensity versus the $\Theta$ and its fitting curve. The variation of intensity $I$ with $\Theta$ is consistent with the derived cosine squared function $I(\Theta) = I_0 \cos^2 \Theta$, where $I_0$ is the light intensity without a polarizer. At $\Theta = 0°$, a maximum transmission was obtained because the polarization of the waveguide mode was parallel to the axis of the polarizer. On the other hand, at $\Theta = 90°$, the transmission decreased to zero because the waveguide mode and the polarizer were cross polarized.

E-O analysis was performed by measuring the variation of the mode intensity when an external field was applied across the ToL waveguide. The polarizer was fixed at $\Theta = 45°$ so the initial intensity was half of its
The maximum found at $\Theta = 0^\circ$. The electric field $E$ across the waveguide was adjusted between 0 to 7.5 V/µm by tuning the voltage $V$ of the power supply. The transient mode intensity $I$ was recorded and drawn in Fig. 6a. The intensity raised sharply whenever an electrical field was applied. Figure 6b displayed the I-V curve extrapolated...

Figure 4. The cross-sectional view of the ToL waveguide from (a) SEM and EDX from (b) Ti K and (c) Nb L emission lines, indicating the TiO$_2$ ridge, Ti electrodes, and the LN substrate, respectively. The TiO$_2$ ridge is 0.8 µm thick and 10 µm wide. The waveguide surface and the interface between the TiO$_2$ and LN was smooth. Ti electrodes were found next to the waveguide.

Figure 5. (a) The optical waveguide mode captured by an MIR camera when the polarizer rotated at different angle $\Theta$. The wavelength was set at $\lambda = 2.5$ µm. The mode decreased as $\Theta$ changed from 0° to 90°. (b) The 1D intensity distribution of the waveguide mode recorded at various $\Theta$. A Gaussian mode profile was found. (c) The plot of the mode relative intensity vs the polarization angle $\Theta$. The red dash line is the fitting result using a cosine square function.
from Fig. 5a and the fitting curve derived from the Pockels effect. The experimentally observed linear E-O response can be described by an equation as

\[ I(V) = I_0 \left( 1 - \cos^2 \left( \frac{\varphi_0 - \pi V}{2V_c} \right) \right) \]  

(1)

The parameter \( V_c = L \cdot \frac{\pi \cdot L}{\gamma_{eff} \cdot \lambda} \) was found for the ToL waveguide. Through the equation

\[ V_c = \frac{g \cdot \lambda}{2 \cdot \gamma_{eff} \cdot n_e^2 \cdot L \cdot \Gamma_{LN}} \]  

(2)

the \( \gamma_{eff} \) was derived as 5.9 pm/V. The resolved \( \gamma_{eff} \) was slightly lower than the \( \gamma_{31} \) of 8.6 pm/V because the waveguide and the electrical field were not strictly parallel to the optical axis of the LN substrate. An even lower \( V_c \) of 7 V·cm can be achieved if the electrode gap \( g \) is narrowed to 3 µm and the waveguide is aligned to the LN y-axis.

Conclusion

Reconfigurable mid-IR photonic circuits were created using a monolithically integrated ToL platform. The device showed smooth waveguide sidewalls and a sharp TiO\(_2\) - LN interface because the waveguide was formed through the lift-off process instead of aggressive etching. After adjusting the thickness of the TiO\(_2\) layer, a hybrid waveguide mode with a large field confinement can be achieved at \( T_{TiO2} = 0.80 \) µm due to an optimized \( \Delta n \) of 0.21 between TiO\(_2\) and LN. The E-O tunability of the ToL waveguide was then realized by applying the Pockels effect from the LN substrate, where a \( \gamma_{eff} \) of 5.9 pm/V, close to \( \gamma_{31} \), was obtained at \( \lambda = 2.5 \) µm. The ToL waveguides provides efficient E-O modulation covering the mid-IR regime thus enabling broad spectrum optical communication.
