Early and Long-term Outcomes of Pneumonectomy for Treating Sequelae of Pulmonary Tuberculosis

Chun Sung Byun, M.D.¹, Kyung Young Chung, M.D.¹, Kyoung Sik Narm, M.D.¹, Jin Gu Lee, M.D.¹, Daejin Hong, M.D.², Chang Young Lee, M.D.¹

**Background:** Pneumonectomy remains the ultimate curative treatment modality for destroyed lung caused by tuberculosis despite multiple risks involved in the procedure. We retrospectively evaluated patients who underwent pneumonectomy for treatment of sequelae of pulmonary tuberculosis to determine the risk factors of early and long-term outcomes.

**Materials and Methods:** Between January 1980 and December 2008, pneumonectomy or pleuropneumonectomy was performed in 73 consecutive patients with destroyed lung caused by tuberculosis. There were 48 patients with empyema (12 with bronchopleural fistula [BPF]), 11 with aspergilloma and 7 with multidrug-resistant tuberculosis.

**Results:** There were 5 operative mortalities (6.8%). One patient had intraoperative uncontrolled arrhythmia, one had a postoperative cardiac arrest, and three had postoperative respiratory failure. A total of 29 patients (39.7%) suffered from postoperative complications. Twelve patients (16.7%) were found to have post-pneumonectomy empyema (PPE), 4 patients had wound infections (5.6%), and 7 patients required re-exploration due to postoperative bleeding (9.7%). The prevalence of PPE increased in patients with preoperative empyema (p=0.019). There were five patients with postoperative BPF, four of which occurred in right-side operation. The only risk factor for BPF was the right-side operation (p=0.023). The 5- and 10-year survival rates were 88.9% and 76.2%, respectively. The risk factors for late deaths were old age (≥50 years, p=0.02) and low predicted postoperative forced expiratory volume in one second (FEV1) (<1.2 L, p=0.02).

**Conclusion:** Although PPE increases in patients with preoperative empyema and postoperative BPF increases in right-side operation, the mortality rates and long-term survival rates were found to be satisfactory. However, the follow-up care for patients with low predicted postoperative FEV1 should continue for prevention and early detection of pulmonary complication related to impaired pulmonary function.

5. Lung function
INTRODUCTION

The role of the thoracic surgeon in managing pulmonary tuberculosis has decreased remarkably since the advent of effective antimicrobial agents and better socioeconomic status. However, pneumonectomy or pleuropneumonectomy is still often required to treat complications of pulmonary tuberculosis such as destroyed lung, empyema, bronchopleural fistula (BPF), or multidrug resistant (MDR) tuberculosis [1].

Solid pleural symphysis and dense fibro-vascular adhesion around the hilum result in intraoperative difficulties in pneumonectomy for inflammatory lung disease. Also, the underlying disease of destroyed lung and a poor health status further worsen a patient’s outcome in the postoperative period. For these reasons, some surgeons have advised to be cautious when deciding whether to perform pneumonectomy [2-4]. However, recent studies have reported acceptably low mortality rates after pneumonectomy for chronic infections [5-9].

We retrospectively evaluated the patients who underwent pneumonectomy or pleuropneumonectomy for treating sequelae of pulmonary tuberculosis to determine the risk factors for early and long-term unfavorable outcomes.

MATERIALS AND METHODS

Between January 1980 and December 2008, 73 consecutive patients who underwent pneumonectomy due to destroyed lung caused by tuberculosis were retrospectively reviewed. Preoperative data collection involved patient demographic data, medical and surgical histories, preoperative medications, presenting symptoms, chest roentgenogram, computed tomography, sputum smear and culture test for acid-fast bacilli, fiberoptic bronchoscopy, preoperative treatment modality, pulmonary function tests, and a quantitative pulmonary perfusion scan. Predicted postoperative (PPO) forced expiratory volume in one second (FEV1) was calculated as follows: PPO FEV1 = Preoperative FEV1 × contribution of contralateral lung.

1) Operative technique

The patients were intubated with a double lumen endotracheal tube and placed in lateral decubitus position. In most cases, surgery was performed through a posterolateral thoracotomy incision. An extrapleural approach (pleuropneumonectomy) was used when the pleural space was completely obliterated due to previous inflammation or empyema. A bronchial stump was stapled and reinforced with pericardial fat or parietal pleura. In some cases, however, reinforcement was omitted based on the choice of the surgeons. In case of spillage to some extent taking place despite careful dissection, copious saline or antiseptic solution irrigation was performed during operation.

(1) Postoperative complications and mortality: Due to the chronic nature of the underlying diseases, in many instances postoperative complications occurred later than 30 days. Therefore, postoperative complications were included on either a 60-day or in-hospital basis. The occurrence of complications requiring treatment (postpneumonectomy empyema [PPE], BPF, bleeding, vocal cord palsy, wound infection or wound dehiscence) was investigated.

(2) Follow-up: The follow-up data were obtained from the outpatient clinic chart reviews or by telephone calls to the patients or their families.

(3) Statistics: Statistical analyses for any correlation between the risk factors and the occurrence of complications were performed with the Chi-square test or Fisher’s exact test. For survival analysis, the Kaplan-Meier method was used. Parametric variables were expressed as mean ± standard deviation and non-parametric variables were expressed as frequency. A p-value less than 0.05 was considered to be statistically significant. All statistical analyses were performed with the SPSS ver. 12.0 (SPSS Inc., Chicago, IL, USA).

RESULTS

Out of 73 patients there were 25 women and 48 men with a mean age of 45.9 years (range, 19 to 70 years). The patients usually presented with the clinical signs of chronic infection and destroyed lung including cough with sputum, a mild to moderate degree of exertional dyspnea, chest discomfort, fever, or hemoptysis. There were 46 patients with empyema (12 with BPF), 11 with aspergilloma, and 7 with MDR tuberculosis. Drainage through the most dependent site was done initially in 34 patients. Sixty-one patients had a history of pulmonary tuberculosis, 28 patients were treated with
Table 1. Patient demographics

| Variables          | Values          |
|--------------------|-----------------|
| Sex                | Male 48 (65.8)  |
|                    | Female 25 (34.2)|
| Age (yr)           | 45.9±14.2       |
| Combined disease   |                 |
| Empyema            | Without BPF 36 (49.3) |
|                    | With BPF 12 (16.4) |
| Aspergilloma       | 11 (15.1)       |
| MDR tuberculosis   | 7 (9.6)         |
| Preoperative FEV1 (L) |               |
| ≥1.8               | 27 (38.6)       |
| <1.8               | 43 (61.4)       |
| Predicted postoperative FEV1 (L) |       |
| ≥1.2               | 35 (71.4)       |
| <1.2               | 14 (28.6)       |
| Operation side     |                 |
| Right              | 24 (32.9)       |
| Left               | 49 (67.1)       |
| Operation time (min) | 282.6±88.2     |
| Range              | 135 – 590       |

Values are presented as number (%) or mean±standard deviation. BPF=bronchopleural fistula; MDR=multidrug resistant; FEV1=forced expiratory volume in 1 second.

Table 2. Postoperative complications

| Complication                        | No. (%) |
|-------------------------------------|---------|
| Postpneumonectomy empyema           | 12 (16.7)|
| With BPF                            | 5 (6.9)  |
| Without BPF                         | 7 (9.7)  |
| Postoperative bleeding               | 7 (9.7)  |
| Vocal cord palsy                     | 2 (2.8)  |
| Wound problem                        | 8 (11.1) |
| Wound infection                      | 4 (5.6)  |
| Wound dehiscence                     | 4 (5.6)  |

BPF=bronchopleural fistula.

Table 3. Analysis of the risk factors for postpneumonectomy empyema

| Risk factor                    | PPE/yes | PPE/no | p-value |
|--------------------------------|---------|--------|---------|
| Preoperative empyema           | 11/48   | 1/24   | 0.040   |
| Preoperative chest tube insertion | 6/34   | 6/38   | 0.572   |
| Side of operation (right)      | 7/23    | 5/49   | 0.069   |
| Operation time (>300 min)      | 5/26    | 7/46   | 0.522   |
| Bleeding (re-exploration)      | 3/7     | 9/65   | 0.606   |
| Preoperative fungal ball        | 1/11    | 11/61  | 0.478   |
| MDR tuberculosis               | 2/7     | 10/65  | 0.522   |
| Pleuropneumonectomy            | 11/51   | 1/21   | 0.068   |
| Intraoperative spillage         | 4/17    | 8/55   | 0.155   |

PPE=postpneumonectomy empyema; MDR=multi drug resistance.

Anti-tuberculous drugs were treated second line anti-tuberculous medication for pulmonary tuberculosis.

The mean operation time was 282.6±88.2 minutes (range, 135 to 590 minutes). Twenty-four patients underwent right-side operation and 49 underwent left-side resection. The preoperative mean FEV1 was 1.68±0.54 L/min (range, 0.66 to 3.50 L/min) and the mean PPO FEV1 was 1.43±0.39 L/min (range, 0.66 to 2.50 L/min) (Table 1). Intraoperative spillage took place in 17 patients during operation in 51 cases (33.3%).

There were 5 operative mortalities (6.8%). One patient had excessive bleeding due to a subclavian vessel injury and developed ventricular fibrillation that could not be corrected. One patient had intraoperative ventricular fibrillation and expired due to arrhythmia during the postoperative course. Postoperative pneumonia and subsequent respiratory failure occurred in 3 patients.

Among 72 patients, excluding one intraoperative death, a total of 29 patients (40.3%) suffered from postoperative complications: 12 (16.7%) patients had PPE, 4 (5.6%) wound infections, 4 (5.6%) wound dehiscence, 7 (9.7%) postoperative bleeding requiring re-exploration, and 2 (2.8%) vocal cord palsy requiring arytenoid reduction. BPF was documented in 5 patients (6.9%) (Table 2).

PPE was the most common postoperative complication. The prevalence of PPE increased in patients with preoperative empyema (p=0.04) (Table 3). Among 7 patients with PPE without BPF, 4 patients proceeded to undergo the Clagett procedure successfully and 3 patients were discharged with open-tube drainage. There were 5 patients with BPF and 4 occurred during right-side operation. The only risk factor for BPF was right-side operation (p=0.023).

Sixty-eight patients were followed for a median of 96.7 months (range, 6 to 353 months). The 5- and 10-year survival rates were 88.9% and 76.2%, respectively. The causes of late death were pneumonia or respiratory failure in 8 and cor pulmonale in 2. The causes of the remaining 5 late deaths
could not be determined.

The risk factors for late death were old age (≥50 years, \( p=0.02 \)) and low predicted postoperative FEV1 (<1.2 L, \( p=0.02 \)) (Fig. 1).

**DISCUSSION**

The present study shows that the mortality rate after pneumonectomy for pulmonary tuberculosis was acceptable considering the difficulties with the surgical technique and patients with poor health status. However, the postoperative complication rate (40.3%) was still high, the prevalence of PPE was higher in patients with preoperative empyema, and BPF was more common in right-side operation. Compared with the high complication rate, the long-term survival rate was found to be satisfactory.

Pneumonectomy for a benign inflammatory lung disease has been considered a high-risk procedure [2-4]. In particular, pneumonectomy for pulmonary tuberculosis is riskier than for other inflammatory disease [5,10-12]. There are three main reasons why the complication rate increases after pneumonectomy in patients with tuberculosis. First, tuberculosis commonly occurs in individuals with poor general health status and the progression to destroyed lung worsens the general status of tuberculosis patients. Second, preoperative empyema is much more commonly associated with tuberculosis than with other underlying diseases of destroyed lung. Third, most patients with tuberculosis have an infected cavity in the parenchyma that attaches strictly to the upper part of the thoracic wall, and it is sometimes impossible to separate it without perforation [5].

Although pneumonectomy for tuberculosis has been consid-
ered a high-risk procedure, there are situations when pneumonec-
omy or pleuropneumonectomy remains the only curative
Treatment modality. Those cases include destroyed lung, un-
controlled hemoptysis, main bronchial stenosis, MDR strain,
and significant symptoms such as productive cough, or repeti-
tive hospitalization. Several authors have reported a 1.1—
8.5% operative mortality from pneumonectomy for inflamma-
atory lung disease [2,6-9,13]. We experienced a 6.8% early
mortality, which was not statistically significant compared
with the mortality (4.5%) of pneumonectomy for lung cancer
during the same period at our institution (p=0.841).

The major concerns among postoperative complications are
PPE and BPF. The risk factors reported for these undesirable
complications reported in the literature were the presence of
preoperative empyema, aspergilloma, excessive blood loss,
right-side operation, intraoperative spillage during operation,
and re-exploration for hemorrhage [2,5,9,13]. The current
study revealed that the presence of preoperative empyema
was a risk factor for the development of PPE.

The presence of preoperative empyema has been considered
an important risk factor for PPE [5]. Odell and Henderson
[14] reported a PPE rate of 45.7% when pneumonectomy
through an empyema was performed. On the other hand, Shiraishi et al. [13] recommended pleuropneumonectomy for
the treatment of empyema with destroyed lung and reported
operative mortality rates of 8.5% and PPE at 9.6% with this
procedure. However, our data shows a high PPE rate of
21.6% in 51 pleuropneumonectomy patients. This result is
thought to be due to an unrecognized intraoperative spillage
due to the presence of preoperative empyema.

Due to the anatomical differences between the right and
left main bronchi, destroyed lung occurs more frequently on
the left side [15]. In this series, 49 out of 73 (67.1%) patients
had left lung destruction. However, BPF followed by pneu-
onecetomy occurred less frequently in left-side operations due
to anatomical peculiarities. The right bronchial stump is more
exposed in the pleural space and less likely to be naturally
buttressed by mediastinal tissues than the left bronchial stump
[16]. This study also showed that there were 5 patients with
BPF and 4 of these BPF occurred during right-side operation
with statistical significance (p=0.023).

Although there are a few papers that have reported long
term survival rates after pneumonectomy for chronic inflamma-
tory lung disease, the long-term survival rates in our
series would seem to be satisfactory. Shiraishi et al. [13] re-
ported a 5-year survival rate of 83% and Kim et al. [9] re-
ported 5- and 10-year survival rates of 94% and 88%,
respectively. The risk factors for late deaths were old age and
low predicted postoperative FEV1. Postoperative FEV1 is
known as a risk factor for early and long-term survival after
pneumonectomy and predicted postoperative FEV1 is corre-
lated with actual postoperative FEV1 [17,18]. This study re-
vealed that low predicted postoperative FEV1 is the risk fac-
tor for long-term survival after pneumonectomy for tuber-
culosus and most patients died of pulmonary complications al-
though some patients were lost to follow-up eventually. These
results suggest that pulmonary complications related to im-
paired pulmonary function may lead to late death. Therefore,
continued surveillance should focus on prevention and early
detection during the follow-up care of patients with low pre-
dicted postoperative FEV1, even if there are no early
complications.

There are some limitations to this study. First, the study
was retrospective and conducted at a single center. Second,
we could not follow-up with some patients completely be-
cause we were short of regular surveillance 2 years after op-
eration in the case of patients without postoperative compli-
cations. Third, preoperative FEV1 does not reflect the accu-
rate postoperative FEV1, so a patient’s prognosis can be pre-
dicted more reliably by measuring postoperative FEV1.

CONCLUSION

Although postoperative empyema increases in patients with
preoperative empyema and postoperative BPF increases in
right-side operation, the mortality rates and long-term survival
rates seem to be satisfactory. However, the follow-up care of
patients with low postoperative predicted FEV1 should con-
tinue for prevention and early detection of pulmonary compli-
cations related to impaired pulmonary function.
