Abstract

Water samples collected from three effluents discharge points into the New Calabar River were analyzed for physicochemical parameters using standard methods. The physicochemical parameters analyzed were colour, odor, temperature, pH, conductivity, total dissolved solids (TDS), turbidity, total suspended solids (TSS), dissolved oxygen (DO), biochemical oxygen demand (BOD), chemical oxygen demand (COD), sulphate (SO\textsubscript{4}\textsuperscript{2-}), phosphate (PO\textsubscript{4}\textsuperscript{3-}), nitrate (NO\textsubscript{3}\textsuperscript{-}) and chloride (Cl\textsuperscript{-}). The result obtained showed that at Iwofe Jetty the water was colourless and odorless but had slight colour and odor at the police post station and Minikpiti station. The range for the parameters obtained in the seasons were: temperature (26.4 ± 1.10-29.0 ± 2.38°C), pH (3.43 ± 0.24-5.06 ± 1.42), conductivity (11.60 ± 2.68-15.61 ± 3.01 µS/cm), TDS (6.53 ± 0.56-8.99 ± 0.98 mg/L), turbidity (9.42 ± 2.68-17.90 ± 3.09 mg/L), TSS (20.53 ± 3.27-33.51 ± 6.25 mg/L), DO (2.62 ± 0.02-5.02 ± 0.31 mg/L), BOD (4.28 ± 1.08-6.11 ± 1.33 mg/L), COD (13.54 ± 3.93-19.16 ± 2.10 mg/L), SO\textsubscript{4}\textsuperscript{2-} (65.92 ± 12.50-346.72 ± 23.22 mg/L), NO\textsubscript{3}\textsuperscript{-} (0.32 ± 0.01-0.53 ± 0.04 mg/L), PO\textsubscript{4}\textsuperscript{3-} (0.34 ± 0.01-0.68 ± 0.03 mg/L) and Cl\textsuperscript{-} (4041 ± 80.50-9411 ± 100.68 mg/L). Generally, the result indicated that colour, odor, pH, turbidity, DO, BOD, COD, and Cl\textsuperscript{-} do not meet the WHO standard for portable water, therefore the water is polluted. The authorities responsible for effluents discharge regulation should therefore monitor the different input sources in order to prevent further increase in pollution of the river.

Keywords: Physicochemical parameters; Pollution; Wastewater; Aquatic organisms

Introduction

It is a known fact that the process in which wastewater or effluents are released into rivers are accompanied by the presence of large quantities of chemical pollutants [1]. Most of the effluents discharged into rivers are either not treated or poorly treated. This may become deleterious to aquatic organisms and other organisms which may eventually make use of such water [2]. Due to ineffective purification systems, wastewater may become seriously dangerous leading to the accumulation of toxic products in the receiving water bodies, with potentially serious consequences on the ecosystem [3]. Furthermore, when an untreated water (whether domestic or industrial) is discharged into any aquatic environment, there is the probability of alteration of the general water chemistry of that water, thus implying that the water has been polluted [4,5]. This is because effluents discharge is usually accompanied with different chemical components. Urban settlements and its associated industrial growth increases human activities within an environment. Sudden rise in human and industrial activities culminates in the production of more waste, which in most cases are discharged into aquatic environments. These chemical laden wastes are harmful to the environment and as such cause serious damage to both plants and animals [6]. Rivers State generally and Port Harcourt in particular, is associated with heavy rains and accompanied with gathering of large pools of water on the road. To overcome this, drainages are built and channeled to rivers. The runoffs from these drainages always transport or transfer all the contents in the drainage to the river. Wastes form homes as well as those from the industries are also carried along. This therefore, add to the general pollution burden of the aquatic environment. One of the pollutants that is commonly associated with effluents discharge is heavy metals. They are known poisons or toxicant at certain concentrations on water and food, even though some may be essential at low concentrations [7]. Heavy metals are dangerous because they tend to bioaccumulate in plant and animal tissues. Bioaccumulation results when there is an increase in the concentration of a chemical in a biological organism over time, compared to the natural concentration of chemicals in environment [8]. However, man’s increased ability to utilize remarkable properties of metals has always resulted in little or significantly large quantities of these metals being discharged into the surrounding as waste and subsequently the environment. This study therefore examined the physicochemical parameters and concentrations of heavy metals at effluents discharge points into the New Calabar River along the Rumuolumeni axis of Port Harcourt, Rivers State.

Materials and Methods

Study area

The water samples were collected from three (3) different discharged points (various locations) namely, Iwofe jetty, Minikpiti and Police Post (Figure 1). The samples were all collected within the Rumuolumeni axis in Obio/Akpor Local Government Area of Rivers State, Nigeria.
Sample collection

Sampling was done during the dry season and wet/rainy season. Water samples were collected during low tide with sample collection bottle or tube at a depth of 10 cm below the water surface. After collection the samples were placed in ice pack containers and then transferred to the laboratory where they were stored at a 4°C. The pre-cleaned sample bottles were initially rinsed with the water samples before collection.

Physicochemical parameters analysis

Colour and odour of the samples were determined by visual and physiological (subjective) examination. pH, conductivity, DO, turbidity and TDS were examined on the spot (in situ) with a hand-held meter HANNA pH meter (Model: HI 98129, Hanna Instruments, California, USA). For the pH, the probes (electrodes) on the instrument were first placed or dipped into two different solutions of acid buffered at pH of 4.0 (acid pH) and 9.0 (alkaline pH) before placing them into the samples to take readings. After which the probes were washed or rinsed in deionized water before the other parameters were measured. Each of the parameters was examined by pressing the button which has the parameter written above it and the value recorded against that parameter.

The samples to take readings. After which the probes were washed or rinsed in deionized water before the other parameters were measured. Each of the parameters was examined by pressing the button which has the parameter written above it and the value recorded against that parameter. Temperature was measured on site with a mercury thermometer. BOD was measured with DO instrument 3900 DR USA.

Results and Discussion

The concentrations of the different physicochemical parameters from the different stations in the different seasons is shown on Tables 1-3.

Colour and odour

The water samples from the Iwofe Jetty station were odourless and colourless, while those of the Minipiti and Police post stations possessed odour and colour. Colour and Odour in water do not exist on their own, but could be traceable to the presence of organic or inorganic contaminants introduced into the water [10]. Some heavy such as iron, copper, zinc etc at high concentrations introduce odour and taste to water. Odour and taste always come together. When water is odorous or has colour, that water is usually rejected by user or consumers. Furthermore, the presence of colour and odour in water is an indication of the presence of volatile organic compounds such as benzene, formaldehyde, toluene, xylene, etc. [11]. The colour and odour from the two stations may have resulted from the stagnant nature of the water which has to wait until high tide before having direct contact with the river water, when compared to that of Iwofe jetty which is discharged directly into the river, which the river current carry away immediately.

Temperature

The temperature of the water at the various station were within acceptable limits of the compared standards. The range of temperature was between 27.0 ± 1.40-29.0 ± 2.38°C in the dry season, while in the rainy season the range was 26.4 ± 1.1-27.0 ± 3.1°C. Temperature is a valuable factor in ecological and physical assessment of water quality. This is because of its influence on both biological and non-biological components of the environment, thus influencing the behaviour of organisms and the proper functioning of an ecosystem [12]. The temperature of any aquatic environment has profound roles to play in reproduction, growth, feeding and immunity of all aquatic or water dwelling plants and animals. If the temperature is too high, the oxygen content of the water is reduced and the function of cells of living organisms is altered, which has direct fatal or mortal consequences on such organisms inhabiting that environment [13].

pH

The pH values obtained from the different locations in both seasons fall within the range of 3.43 ± 0.24-5.06 ± 1.42. However, the pH values were higher in the rainy season than the dry season. The increase in the pH values during the rainy season may have resulted from the dilution factor due to increased water input from rain. The values obtained were lower than the recommended pH value for drinking or domestic purposes by the sited agencies [14]. The pH values obtained in the different discharge points were all acidic in nature similar to those observed in another study [15]. When water is acidic, it enhances corrosion of metal pipes, cement wall and plumbing processes, but when the water is alkaline in nature, it shows that the water is disinfected and suitable for use [10,16]. The acidic nature of the water samples from the various sample points can be attributed to the type of effluents discharged into the river through domestic and industrial activities. When the pH values of any water is at the extremes, the taste and sweetness of the water is affected. The effectiveness of biochemical reactions depends on pH. Furthermore, other important reactions and parameters in water are governed by the concentration of the hydronium ion (H+). Such parameters include ammonia and solubility of metal ions [11].

| Parameter         | Location          |
|-------------------|-------------------|
|                  | Iwofe Jetty       | Minipiti         | Police Post      |
| Colour           | Colourless        | Slightly coloured| Slightly coloured|
| Odor             | Odorless          | Foul odor        | Foul odor        |
| Temperature (oC) | 29.0 ± 2.38       | 27.5 ± 1.33      | 27.0 ± 1.40      |
| pH               | 3.43 ± 0.24       | 4.26 ± 0.33      | 4.15 ± 0.02      |

Table 1: Physicochemical parameters of water samples from the discharge points into the New Calabar River in the dry season.

| Parameter       | Mean ± Standard Deviation |
|-----------------|---------------------------|
| Conductivity (μS/cm) | 15.61 ± 3.01             |
| TDS (mg/L)      | 8.89 ± 0.98               |
| Turbidity (NTU) | 15.07 ± 2.66              |
| TSS (mg/L)      | 31.31 ± 4.91              |
| DO (mg/L)       | 2.62 ± 0.02               |
| BOD (mg/L)      | 6.11 ± 1.33               |
| COD (mg/L)      | 19.16 ± 2.10              |
| SO$_4^{2-}$ (mg/L) | 74.16 ± 8.35         |
| NO$_3$ (mg/L)   | 0.53 ± 0.04               |
| PO$_4^{3-}$ (mg/L) | 0.68 ± 0.03           |
| TSS (mg/L)      | 31.31 ± 4.91              |
| BOD (mg/L)      | 6.11 ± 1.33               |
| COD (mg/L)      | 19.16 ± 2.10              |
| SO$_4^{2-}$ (mg/L) | 74.16 ± 8.35         |
| NO$_3$ (mg/L)   | 0.53 ± 0.04               |
| PO$_4^{3-}$ (mg/L) | 0.68 ± 0.03           |
| Cr (mg/L)       | 9.411 ± 100.68            |

**Conductivity**

The values observed for conductivity in this work were lower than the desired or recommended value by WHO. There was no difference in the values obtained in the various stations within the seasons. The expression of the ability of water to conduct electricity is known as conductivity. The conductivity of any water or aquatic body is dependent on concentration of ions or current carrying species present in the water [17]. Since conductivity is a function of the ionic content of the sample, which gives an idea of the amount of dissolved ions or electrolytes present in the sample, it becomes a very important parameter or tool to indicate or examine the hardness and alkalinity of water [18]. The values obtained for conductivity in this work were quite lower than those of Abdar et al. [18] in Morna Lake, Shirala, India and those observed by Sharma et al. [17] in Satluj River, Himachal Pradesh, India.

**Total Suspended Solids (TSS)**

The mean value of TSS observed in this work was 7.31 mg/L, a value which was far below the WHO standard of 250-500 mg/L. TSS is a measure of both inorganic and organic matter that are dissolved or are found in solution in water [16]. The extent of pollution of any water or aquatic environment can be expressed in terms of the amount, value or quantity of TSS present. The degree of contamination or pollution of water has direct proportionality to the concentration of TSS. It is expected that the TSS value in the rainy season should be higher than those of the dry season due to water runoffs as was observed in another study [19,20], but this was not so. This situation may have arisen as a result of the time and nature of sampling or from the built up of the drainage from which the effluent and rain water are being discharged. To properly manage any treatment system, the analysis of TSS should be properly done since it is a very important parameter which controls both physical and biological wastewater treatment or purification processes [21].

**Turbidity**

Turbidity is a measure of the transparency or opacity of water. Any water which contains high level of suspended and dissolved particles have the tendency to possess very high values of turbidity. The observed turbidity values were slightly higher in the rainy season when compared to those of the rainy seasons. The average values obtained was 12.48 NTU which was 2.5 times the WHO value of 5 NTU. When there is increased turbidity of waterbody, it interferes with the penetration of light through water. This will impairment or destroy the nature of aquatic life exhibited by biotic organisms and also depreciate the value of surface water [22]. During the wet or rainy season, runoffs usually wash off surface soil into water bodies thus increasing the concentration of suspended solids which subsequently increase the turbidity [23].

**Total Suspended Solids (TSS)**

The mean value of total suspended solids was 26.97 mg/L, however, the values at the Iwofe Jetty in both seasons were slightly higher than the standard requirement of 30 mg/L by WHO. The values of TSS observed in this work was higher than those observed in another study [24]. When there is increased TSS, the turbidity of the water is increased. Land use system such as farming, construction, mining, etc., exposes soil surfaces to erosion and runoffs, which adds to the aquatic load of suspended particles. Suspended solids or particles in waterbody is more of a function of natural occurrence or causes rather than anthropogenic. Suspended solid particles are either organic or inorganic components such as algae, silt and sediment. Another factor that can cause increase in the amount of TSS is re-suspension of sediment resulting from seasonal water variations and flows. However, excess concentrations above the expected background value is a consequence of direct or indirect human activity.

**Dissolved Oxygen (DO)**

The average value of DO observed was 3.74 mg/L as against the 10 mg/L recommended by WHO. The values were lower in all the stations and seasons. DO is considered as one of the most important water quality parameters because aquatic life depends on the amount of oxygen present in the water to be utilized by aquatic biota. The concentration of Dissolved oxygen in water is very informative due to the fact that it can be used to ascertain the level of bacterial activity, photosynthesis, nutrients availability, stratification and survival of fishes [25]. Dissolved oxygen (DO) is reduced in aquatic media during dry season due to increase in temperature and enhanced microbial activity [26]. The above statement agrees with findings of this work where lower values of DO was observed in dry season than the rainy season. High temperatures reduces solubility of gases in water and also sunlight facilitates photosynthetic processes by phytoplankton, by utilizing more CO$_2$ and giving off oxygen, Thus, accounting for the higher values of DO observed during wet or rainy season [27].

**Biochemical Oxygen Demand (BOD)**

The average BOD values observed in this work was 4.92 mg/L, which was higher than the WHO recommended value of 4.0 mg/L. The values obtained in the present work is far lower than those observed by Yapo et al. [28] from waste water in Abijan, which was 14500 mg/L. BOD is used to express the level contamination of water by organic material. It is the quantity or level of oxygen dissolved in water that is needed or required for biochemical oxidation, breakdown or
disintegration of organic and some certain inorganic materials by micro-organism [29]. It is used to assess the degree of pollution of surface and ground waters where there is disposal of domestic and industrial effluents [30]. Although the WHO maximum requirement for BOD in water is 4.0 mg/L, yet 1.0 mg/L is most appropriate for drinking water. Values of BOD up to 5.0 mg/L gives a serious doubt on the portability of water due to the presence of bio-organisms.

**Chemical Oxygen Demand (COD)**

The mean value of COD in this research was 16.41 mg/L, which was higher than the WHO recommended value of 10 mg/L. The highest concentration was observed at the Iwofe Jetty in the dry season, with a concentration of 19.16 mg/L. COD is also a measure of the concentration of organic material pollution or pollution in water. The chemical oxidation of organic matter present requires a certain amount of dissolved oxygen that should be present. It is the quantity of dissolved oxygen that is used up to achieve this oxidation that is referred to as COD [17]. COD like BOD is an important indicator of environmental health of any surface water before supply for consumption.

**Nitrate (NO₃⁻)**

The mean value of nitrates in the present research work was 0.415 mg/L. The highest concentration of was observed at the Iwofe Jetty station. The observed values from the different stations were lower than the WHO limit of 50 mg/L for drinking water. The values obtained in this work though very low, yet are higher than the values obtained by Abdar et al. [18] in Morna Lake, Shirala, India, where he obtained a concentration range of 0.0157-0.032 mg/L. Proteins, chlorophyll and other organic matter are the sources by which nitrates are transmitted to river.

**Phosphate (PO₄³⁻)**

Phosphates in aquatic environment in most cases are present in the form of Orthophosphates (PO₄³⁻). In the present research the observed mean phosphate was 0.46 mg/L, which was a little lower than the WHO value of 0.5 mg/L. The highest concentration of phosphorus was observed in the dry season at the Iwofe Jetty station, which was 0.68 ± 0.03 mg/L. Sources of phosphate enrichment in any waterbody can be from runoffs, decay of organic materials, excreta from animals and effluents from industrial discharges from fertilizer companies. Phosphate explosion results in algal growth and subsequent eutrophication of lakes or stagnant pool of water [10].

**Chloride (Cl⁻)**

The mean concentration of chloride ion in the water samples in this research was 6550.83 mg/L, which was higher than the 250 mg/L required by WHO. The very high level of chloride in the present work may have arisen from inflow of sea water during high tide. Sources of chloride in water arise majorly from re-suspension of chloride contaminated sediments, sewage and industrial discharges. One major effect of chloride in water is the enhancement of the electrical conductivity of water and corrosion of metals on contact with the water. Metals in the presence of chlorides react to give soluble salts [14], thereby increasing the concentration of metals in water. Both galvanic and pitting corrosion are enhanced by the presence of chlorides [14,33].

| Parameter | Location          | Present Work | WHO Standard | SON Standard |
|-----------|-------------------|--------------|--------------|--------------|
| Colour    | Iwofe Jetty       | Colourless   | Slightly coloured | Slightly coloured |
| Odor      | Iwofe Jetty       | Odorless     | Foul odor    | Foul odor    |
| Temperature (°C) | Iwofe Jetty | 27.0 ± 3.1 | 26.5 ± 2.0 | 26.4 ± 1.1 |
| pH        | Iwofe Jetty       | 4.63 ± 0.33 | 5.06 ± 1.42 | 4.89 ± 1.01 |
| Conductivity (µS/cm) | Iwofe Jetty | 14.52 ± 2.98 | 12.71 ± 1.67 | 12.42 ± 2.66 |
| TDS (mg/L) | Iwofe Jetty       | 7.69 ± 2.11 | 6.73 ± 1.33 | 7.02 ± 1.45 |
| Turbidity (NTU) | Iwofe Jetty | 17.90 ± 3.09 | 11.72 ± 2.63 | 9.98 ± 2.68 |
| TSS (mg/L) | Iwofe Jetty       | 33.51 ± 6.25 | 25.28 ± 4.96 | 26.65 ± 3.78 |
| DO (mg/L)  | Iwofe Jetty       | 3.26 ± 0.02 | 4.42 ± 0.28 | 5.02 ± 0.31 |
| BOD (mg/L) | Iwofe Jetty       | 5.12 ± 0.23 | 4.28 ± 1.05 | 4.80 ± 0.87 |
| COD (mg/L) | Iwofe Jetty       | 17.32 ± 1.66 | 13.54 ± 3.93 | 14.67 ± 2.67 |
| SO₄²⁻ (mg/L) | Iwofe Jetty | 65.92 ± 12.50 | 240.83 ± 28.19 | 300.41 ± 16.60 |
| NO₂⁻ (mg/L) | Iwofe Jetty       | 0.51 ± 0.08 | 0.400 ± 0.00 | 0.32 ± 0.01 |
| PO₄³⁻ (mg/L) | Iwofe Jetty | 0.56 ± 0.00 | 0.34 ± 0.11 | 0.38 ± 0.05 |
| Cl⁻ (mg/L) | Iwofe Jetty       | 6.922 ± 87.32 | 4.885 ± 77.10 | 4.041 ± 80.50 |

Table 2: Physicochemical parameters of water samples from the discharge points into the New Calabar River in the Rainy season.

**Sulphate (SO₄²⁻)**

The mean concentration of Sulphate (SO₄²⁻) in the present work was 219.81 mg/L, which was lower than the WHO set limit of 250-500 mg/L. The highest value of 346.72 ± 23.22 mg/L was observed at the Police post station, which is within the set limit for drinking water. The values obtained for sulphate were higher than those of other authors [31,32] in a Nigerian and Wales rivers respectively.
Table 3: Mean values of physicochemical parameters from the different stations compared with different Standards.

| Parameter | Mean (mg/L) |
|-----------|-------------|
| pH | 7.5 |
| Temperature | 25°C |
| Total Hardness | 50 mg/L |
| Chloride | 25 mg/L |
| Nitrate | 10 mg/L |
| Sulfate | 20 mg/L |
| Dissolved Oxygen | 6 mg/L |

Conclusion

The need to arrive at and effective and standard regulatory agencies to properly regulate industrial inputs into rivers is tasking and therefore need commitment. The Nigerian ecological existence is under serious environmental question with the level of unchecked or monitored effluents discharge sources. The present work suggests that the water at the effluents discharge points is polluted and therefore not fit for any form of human consumption. Therefore, adequate monitoring standards should be put in place to check both industrial and domestic sources where these effluents are initially discharged into the drainage system to enable an ecological viable environment.
