Abstract

Drug resistance in protozoan parasites has been associated with the P-glycoprotein (Pgp), an energy-dependent efflux pump that transports substances across the membrane. Interestingly, the genes *TcPGP1* and *TcPGP2* have been described in *Trypanosoma cruzi*, although the function of these genes has not been fully elucidated. The main goal of this work was to investigate Pgp efflux pump activity and expression in *T. cruzi* lines submitted to in vitro induced resistance to the compounds 4-N-(2-methoxy styryl)-thiosemicarbazone (2-Meotio) and benznidazole (Bz) and to verify the stability of the resistant phenotypes during the parasite life cycle. We observed that the EC$_{50}$ values for the treatment of epimastigotes with 2-Meotio or Bz were increased at least 4.7-fold in resistant lines, and this phenotype was maintained in metacyclic trypomastigotes, cell-derived trypomastigotes, and intracellular amastigotes. However, in epimastigotes, 2-Meotio resistance is reversible, but Bz resistance is irreversible. When compared with the parental line, the resistant lines exhibited higher Pgp efflux activity, reversion of the resistant phenotypes in the presence of Pgp inhibitors, cross-resistance with Pgp modulators, higher basal Pgp ATPase activity, and overexpression of the genes *TcPGP1* and *TcPGP2*. In conclusion, the resistance induced in *T. cruzi* by the compounds 2-Meotio and Bz is maintained during the entire parasite life cycle. Furthermore, our data suggest the participation of the Pgp efflux pump in *T. cruzi* drug resistance.

Introduction

Chagas disease, caused by the protozoan parasite *Trypanosoma* (Schizotrypanum) *cruzi*, is endemic in Latin America and affects approximately 10 million people (WHO 2010).
Additionally, the prevalence of the disease has been increasing in non-endemic areas such as North America (Bern et al. 2011) and Europe (Muñoz et al. 2009; Jackson et al. 2010) due to human migration. The only available drugs for the treatment of Chagas disease are benznidazole and nifurtimox, which have limited efficacy during the chronic phase of the infection, require long treatment periods, and have potentially harmful side effects (Castro et al. 2006; Caldas et al. 2008). In addition, several T. cruzi strains have shown to be naturally resistant to these compounds (Filardi and Brener 1987), and the resistance may also be induced by maintaining the parasite under prolonged drug pressure (Nirdé et al. 1995; Dos Santos et al. 2008).

The need for a safer and more efficient compound for the treatment of Chagas disease than current alternatives has led several groups to study the trypanocidal properties of natural and synthetic compounds (Campos et al. 2010; Dos Santos Gomes et al. 2012). Recently, Soares et al. (2011) verified that the synthetic compound 4-N-(2'-methoxy styryl)-thiosemicarbazone has a potent and selective cytotoxic effect on different developmental forms of T. cruzi, encouraging its use in further studies that are focused on finding new treatments for the disease. However, studies have shown that prolonged treatment with thiosemicarbazones in cancer cell lines may induce resistance and that this phenotype is associated with overexpression of the mdr-1 gene, which codes for the P-glycoprotein (Pgp) (Rappa et al. 1997; Liu et al. 2009).

Pgp (also known as ABCB1) is a transmembrane protein that belongs to the superfamily of ABC transporters and acts as an energy-dependent efflux pump to transport substances across membranes (Higgins 1992). This protein has been associated with the multidrug resistance phenotype (MDR), which is characterized by cross-resistance to multiple unrelated cytotoxic agents in tumor cells (Shustik et al. 1995) and protozoan parasites such as Plasmodium falciparum (Wilson et al. 1993), Leishmania tropica (Gamarro et al. 1994), Leishmania amazonensis (Gueiros-Filho et al. 1995), and Entamoeba histolytica (Descoteaux et al. 1995). Interestingly, the mdr-like genes TcPGP1 (Torres et al. 1999) and TcPGP2 (Dallagiovanna et al. 1996) have been described in T. cruzi, although their drug efflux activity has not been investigated. In the present work, we examined whether the T. cruzi Y strain would develop resistance to thiosemicarbazone and benznidazole (Bz) in vitro and maintain this phenotype through its life cycle, and studied the association between drug resistance and the activity and expression of P-glycoprotein in this parasite.

**Material and methods**

Unless specifically indicated otherwise, all reagents were acquired from Sigma Aldrich, Brazil.

**Parasite**

T. cruzi epimastigotes, Y strain (Silva and Nussenzweig 1953), were cultivated at 26 °C in liver infusion tryptose medium (LIT medium) supplemented with 10 % heat-inactivated fetal calf serum, 100 U/mL penicillin, and 100 mg/mL streptomycin. The epimastigote forms were collected during the log phase of cell culture growth.

**Effect of the compounds on T. cruzi epimastigotes**

Epimastigotes forms (final concentration of 5×10^6/mL) were incubated in LIT medium in the presence of the compounds 4-N-(2-methoxy styryl)-thiosemicarbazone (2-Meotio) (Soares et al. 2011) or Bz (N-Benzyl-2-nitro-1H-imidazole-1-acetamide, Roche, Brazil) prepared in dimethylsulfoxide (Merck, Germany) at concentrations ranging from 25 to 400 μM (the final solvent concentration did not exceed 1.6 %). The bioassays were performed at 26 °C/24 h in 96-well plates. The cells were counted using a Neubauer chamber to determine the EC_{50} values, corresponding to the effective dose that kills 50 % of the parasites. Untreated parasites were used as controls.

**Induction of resistance to Bz or 2-Meotio in T. cruzi epimastigotes**

T. cruzi epimastigotes were seeded at 5×10^6/mL in LIT medium containing 2-Meotio or Bz at their respective EC_{50} concentrations, 71.7 and 182.1 μM. After 24 h, the medium was replaced with LIT not containing any drug, allowing the replication of surviving parasites. Seven-day-old culture parasites were then submitted to the same respective drug concentrations, and this operation was repeated for ten weekly passages before increasing the drug level (Nirdé et al. 1995). From the 11th passage onwards, the drug concentration used to induce resistance was gradually increased in 10-μM steps until the 15th passage was reached. Resistance induction was analyzed by performing a new screening after each passage and comparing the EC_{50} values. The persistence of the resistant phenotypes was evaluated by cultivating the parasites in vitro without drug pressure for 6 months.

**Effect on metacyclic and cell-derived trypomastigotes**

To determine whether the resistance would be maintained throughout the parasite life cycle, parental and resistant epimastigotes were cultivated in LIT medium without repossession for 20 days, and the resulting nutritional stress allowed their transformation to metacyclic trypomastigotes. Aiming to kill the remaining epimastigotes, the parasites were treated with 10 % human serum diluted in RPMI-1640 medium for
30 min at 37 °C. After morphological transformation, the parasites were fixed and stained using the Panótico Rápido kit (Laborclin, Pinhais, Parana, Brazil) and examined using light microscopy. Metacyclic trypomastigotes were utilized for (a) a screening assay using the compounds Bz and 2-Meotio, (b) infection of LLC-MK2 cells (1×10^6 parasites) to obtain cell-derived trypomastigotes, and (c) infection of peritoneal macrophages to obtain intracellular amastigotes. The screening protocol for both metacyclic and cell-derived trypomastigotes was the same as those used for the epimastigote forms except for the incubation conditions (37 °C in a 5% CO₂ atmosphere at 98% humidity).

Growth inhibition of intracellular amastigotes

Macrophages were isolated from the peritoneal cavity of Balb/c mice in cold RPMI 1640 medium supplemented with 10% FCS and 2 mM L-glutamine, 100 U/mL penicillin, and 100 mg/mL streptomycin. The cells (2×10^6 per well) were maintained at 37 °C in a humidified 5% CO₂ atmosphere. All assays were carried out using a protocol that was approved by the animal use ethical committee (Comissão de Ética no Uso de Animais CEUA/Fiocruz (P-369/07L-013/08)). These cells were utilized in the following assays:

Cytotoxicity

The cells were treated with 2-Meotio or Bz at various concentrations (12.5 to 50 μM) for 24 h, and their viability was measured using the 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl-tetrazolium bromide dye reduction assay as described by Mosmann (1983). The absorbance was measured at 490 nm using a VERSAmax tunable spectrophotometer (Molecular Devices, Sunnyvale, CA, USA).

Effect on intracellular amastigotes

The macrophages were plated in Lab-Tek tissue chamber slides and infected with 2×10^7 metacyclic trypomastigote forms of parental or resistant lines for 3 h. After this time, the cells were cultured in RPMI medium in the absence or presence of various drug concentrations (12.5 to 50 μM) for 24 h. The cultures were fixed with methanol, stained (with Panótico Rápido as described above), and analyzed using optical microscopy. The intracellular amastigotes were quantified as the mean±SD of three experiments carried out in duplicate, and the drug activity was analyzed as the endocytic index (number of parasites/100 cells) (Silva et al. 2007).

Rhodamine 123 efflux assay

The parental and resistant lines were resuspended at a density of 5×10^5 parasites/mL in phosphate-buffered saline (PBS), and the resistant lines were incubated at 26 °C for 15 min in the presence or absence of 2 μM of the Pgp inhibitors verapamil or cyclosporin A (Búa et al. 2008). The parasites were then pelleted at 2,000×g for 10 min, resuspended in 1 ml PBS containing 20 μg/mL of Rhodamine 123 fluorescent probe, and incubated for 5 min at 26 °C. The parasites were washed twice with ice-cold PBS, and the fluorescence was measured at excitation and emission wavelengths of 485 and 530 nm, respectively, using a FACSCalibur flow cytometer (BD Biosciences, San Jose, CA, USA). Experiments were performed using duplicate samples in four independent experiments, and the data were analyzed using Summit software (Dako Colorado Inc., Fort Collins, CO, USA).

Reversion of resistance and cross-resistance assays

To investigate whether co-treatment of the parasites with Bz or 2-Meotio plus Pgp inhibitors would revert the resistant phenotype, epimastigote forms of parental and resistant lines were treated with the compounds 2-Meotio or Bz in the presence of 2 μM of verapamil or 2 μM of cyclosporin A for 24 h at 26 °C. The treatment of parental, M15 and B15 lines with only 2 μM of verapamil or 2 μM of cyclosporin A was performed as a control. The effect of daunorubicin, paclitaxel, and vinblastine on parental and resistant lines was evaluated to verify whether the parasites that were resistant to Bz or 2-Meotio were also resistant to Pgp modulators. Both assays were performed using the same protocol described in “Effect of the compounds on T. cruzi epimastigotes” section.

Pgp ATPase activity assay

The abilities of compounds to stimulate ATP hydrolysis were examined using recombinant human Pgp membranes and measured using the Pgp-Glo™ Assay kit (Promega, Madison, WI, USA). Briefly, 25 μg of Pgp was incubated with a range of Bz or 2-Meotio concentrations (25–800 μM) in the presence of MgATP (5 mM) for 40 min at 37 °C. Sodium orthovanadate (SOV, an ATPase activity inhibitor) was assayed in parallel. SOV-sensitive ATP hydrolysis was determined by subtracting the value obtained using the SOV co-incubated Pgp membrane to those obtained using the SOV-free Pgp membrane. The reaction was measured using a GloMax®-Multi Microplate Luminometer (Promega, Madison, WI, USA). The EC_{50} (the concentration that stimulates 50% of ATPase activity) was calculated.

The T. cruzi membrane fractions used were obtained from epimastigote forms of T. cruzi parental and resistant lines. Parasites (1×10^10) were resuspended in hypotonic lysis buffer (10 mM Tris–HCl pH 7.4–7.6, 10 mM NaCl, 1.5 mM MgCl₂,
and 1 mM dithiothreitol) and mechanically lysed as described by Previato et al. (1998). After differential centrifugation (1,500 g, 10 min and 4 °C), the unbroken cells and nuclei were removed, and the enriched membrane fraction was obtained according to Lux et al. (2000). The protein concentration was measured using the Bradford method (Bio-Rad Protein Assay kit, Hercules, CA, USA), and the samples were stored at −20 °C until use. These fractions were incubated with MgATP (5 mM) for 40 min at 37 °C in the presence or absence of Bz (182.1 μM) or 2-Meotio (71.7 μM). In parallel, the fractions were incubated with 100 μM cyclosporin A (a specific Pgp ATPase inhibitor). Cyclosporin A-sensitive ATP hydrolysis was determined by subtracting the value obtained using the cyclosporin A co-incubated membrane fraction with that obtained using the Cyclosporin A-free membrane fraction. The ATPase activity of the parental and resistant lines was also evaluated in the presence of non-Pgp ATPase inhibitors [AEO solution: sodium azide, EGTA and ouabain, together with verapamil (a well-known Pgp ATPase activity stimulator) (Ambudkar 1998)].

RNA extraction and quantitative real-time RT-PCR

Total RNAs from parental and resistant lines of T. cruzi epimastigotes were extracted using TRIzol reagent (Invitrogen, Carlsbad, CA, USA). The 143- and 136-bp segments corresponding to the TcPGP1 (GenBank ID: U95956) and TcPGP2 (GenBank ID: Z49222) genes, respectively, were amplified using the following primers: TcPGP1-forward 5′-GATGCGCGATGACGGGTATG-3′ and TcPGP1-reverse 5′-TCG GTCAAATGTGGAGATGG-3′; TcPGP2-forward 5′-TGGCGTTGT TTATTGTGC-3′ and TcPGP2-reverse 5′-GCCACAAGGGCACCTTCTC-3′. Reverse transcription was carried out using the SuperScript III First-Strand Synthesis System for RT-PCR (Invitrogen, USA). Quantitative real-time RT-PCR was conducted using an ABI PRISM 7500 Sequence Detection System (Applied Biosystems, Foster City, CA, USA) using the Power SYBR Green PCR Master Mix and 1 μL of each primer (400 nmolar/rx) in a final volume of 25 μL. The cDNA was amplified at 95 °C for 10 min followed by 40 cycles of 95 °C for 15 s and 60 °C for 1 min. A reverse transcription negative control (without reverse transcriptase) and a non-template negative control were included for each primer set to confirm the absence of genomic DNA and to test for primer dimers and contamination in the reactions, respectively. To ensure that only a single product was amplified, a melting curve analysis was performed. Relative mRNA levels were normalized against the level of β actin (internal reference) mRNA. All data were expressed as the mean±SD of three independent experiments (each in triplicate).

Statistical analysis

Statistical analyses were performed using one-way analysis of variance and Bonferroni’s test (GraphPad Software, La Jolla, CA, USA). Differences were considered significant when p<0.05.

Results

Drug resistance induction and follow-up during the T. cruzi life cycle

The EC50 value for the treatment of epimastigotes with 2-Meotio increased from 71.7 to 350.7 μM by the 15th passage under drug pressure. At the same time, the EC50 value for the treatment with Bz was 4.7-fold higher in the resistant line (Table 1). The resistant lines obtained after the 15th passage were termed M15 (resistant to 2-Meotio) and B15 (resistant to Bz). The resistance induced in the epimastigotes was maintained after transformation to metacyclic trypomastigotes, cell-derived trypomastigotes, and intracellular amastigotes in both the M15 and B15 lines, as seen from the significant increase in EC50 values (Table 2). Additionally, the treatment with 2-Meotio (from 12.5 to 50 μM) did not reduce the endocytic index in cells infected with the M15 line as it did in those infected with the parental line (Fig. 1A, B). Similar results were obtained for the treatment with Bz.

| Passagesa | ED50/24h (μM)b |
|-----------|----------------|
|           | 2-Meotio | Bz                  |
| Parental  | 71.7±4.4 | 182.1±10.7          |
| 3rd       | 76.6±4.2 | 299.1±2.6           |
| 5th       | 125.3±14.3| 357.7±36.8          |
| 8th       | 203.7±9.1| 474.1±15.7          |
| 10th      | 252.8±9.8| 492.5±14.2          |
| 12th      | 350.9±18.0| 684.8±61.9          |
| 15th      | 350.7±11.2| 863.3±53.0          |

Notes:
a Number of consecutive passages (in vitro) in the presence of each compound
b Mean±SD of at least three independent experiments
c T. cruzi line resistant to 2-Meotio (M15)
d T. cruzi line resistant to Bz (B15)
for cells infected with the parental or B15 lines, showing that the resistant phenotype was maintained (Fig. 1C, D). From the fourth month of cultivation in the absence of drug onwards, a continuous decrease in the EC_{50} value was observed for the treatment with 2-Meotio in the M15 line, until it reached the same value as that observed for the parental line (Figs. 2a), indicating reversibility of the resistance. On the other hand, the resistance to Bz was maintained even after 6 months of cultivation without drug pressure (Fig. 2b), indicating irreversible resistance.

### Pgp efflux activity

To investigate the association between Pgp activity and *T. cruzi* drug resistance, we performed a Rhodamine 123 fluorescence assay. This molecular probe mimics some Pgp substrates and has been used to investigate the Pgp efflux of 50 μM benznidazole (Bz) on the interaction of peritoneal macrophages with parental or resistant lines of *T. cruzi* (Y strain) for 24 h. A) The effect of 50 μM 2-Meotio on the interaction between peritoneal macrophages and parental or resistant lines of *T. cruzi* (Y strain) for 24 h. a, b Parental line untreated and treated with 2-Meotio. c, d M15 line untreated and treated with 2-Meotio. Magnification ×40. B) Endocytic Index (the percentage of infected cells versus the number of intracellular amastigotes) for the treatment of *T. cruzi* with 2-Meotio. C) The effect of 50 μM benznidazole (Bz) on the interaction of peritoneal macrophages with parental or resistant lines of *T. cruzi* (Y strain) for 24 h. a, b Parental line untreated and treated with Bz. c, d B15 line untreated and treated with Bz. Magnification ×40. D) Endocytic Index for the treatment of *T. cruzi* with Bz for 24 h. Asterisk, significant difference in the parental line when comparing the endocytic index in the treated group versus the control.
activity in parasite and human cell lines (Gueiros-Filho et al. 1995; Gupta et al. 2011).

Figure 3 shows that the fluorescence exhibited by the M15 and B15 lines was, respectively, 39.4 and 50.8 % lower than that exhibited by the parental line, indicating that there was an efflux of Rhodamine by the resistant parasites. Furthermore, Rhodamine fluorescence inside the resistant lines increased significantly after treatment with the Pgp inhibitors cyclosporin A (CsA; Fig. 3a, b) or verapamil (VP; Fig. 3c, d) due to inhibition of the Pgp efflux activity.

To determine whether the resistance phenotype was reversible, the M15 line was co-treated with 2-Meotio plus either CsA or VP (Fig. 3e), and the B15 line was co-treated with Bz plus either CsA or VP (Fig. 3f) in the screening assay. A significant reduction of the EC_{50} values was observed in comparison with the treatments with 2-Meotio alone (Fig. 3e) or Bz alone (Fig. 3f). In a parallel experiment, it was observed that the treatment with 2 μM VP alone or 2 μM CA alone did not affect parasite proliferation.

In the cross-resistance assay, it was shown that the M15 line, which is resistant to 2-Meotio, is also more resistant to the compounds Bz, vinblastine, and daunorubicin than is the parental line. It was also observed that the B15 line is more resistant not only to Bz but also to the Pgp modulators vinblastine, paclitaxel, and daunorubicin compared to the parental line (Table 3).

**Pgp ATPase activity**

The effect of various concentrations of 2-Meotio and Bz on recombinant human Pgp ATPase activity was evaluated. Both compounds stimulated ATPase activity with EC_{50} values of 134 and 277.1 μM, respectively (Fig. 4a). The effects of cyclosporin A and the AEO solution (which contains three ATPase inhibitors; see “Material and methods” section) were also tested. Verapamil was used as a positive control. Verapamil stimulates, cyclosporin A inhibits, and the AEO solution has no effect on Pgp ATPase activity (see Appendix). Subsequently, the Pgp ATPase activity of *T. cruzi*-enriched membrane fractions was analyzed. Higher basal Pgp ATPase activity was observed in the membrane fractions of the resistant lines M15 and B15 compared with that observed in the parental line (Fig. 4b, c). In addition, the compounds 2-Meotio or Bz stimulated ATP hydrolyses in the resistant lines M15 and B15, respectively. In parallel, basal Pgp ATPase activity was also evaluated by measuring ATPase activity in the presence of the AEO solution, which inhibits only non-Pgp ATPases, and the previous results were corroborated (see Appendix).

**Pgp expression assay**

The expression of the *TcPGP1* gene was 1.7-fold higher in the B15 line and 2.7-fold higher in the M15 line than in the parental line. Similarly, the expression of the *TcPGP2* gene was 1.6-fold higher in the B15 line and 1.5-fold higher in the M15 line than in the parental line (Fig. 5).

**Discussion**

Drug resistance in *T. cruzi* is considered a major problem for the treatment of Chagas disease, not only because of the natural resistance of some strains to benznidazole (Andrade et al. 1985; Toledo et al. 1997) but also because of the ability of this drug to induce resistance in *T. cruzi* experimentally (Murtuza and Romanha 1998). This easily achieved resistance phenotype may be associated with the therapeutic failures observed during the chronic phase of the illness because long-term treatment is required to control the infection. In this study, we demonstrated that both benznidazole and the thiosemicarbazone 2-Meotio can induce resistance in the Y strain of *T. cruzi* in vitro.
Resistance to various types of thiosemicarbazones in cancer cell lines has been extensively investigated and appears to be mediated by either qualitative or quantitative alterations in P-glycoprotein. Rappa et al. (1997) reported that resistance to 3AP in L1210 MQ-580 cells is associated with the overexpression of the multidrug resistance gene \textit{mdrl}. Likewise, Pgp overexpression has also been demonstrated in cancer cell lines that are resistant to the

\(a\) Mean±SD of at least three independent experiments

\(b\) Significant difference for each compound in relation to the parental line
compounds MAIQ (Cory et al. 1997) and 64Cu-ATSM (Liu et al. 2009). In addition, qualitative modifications, such as polymorphism of the mdr1 gene, can also result in resistance to thiosemicarbazones (Choi et al. 2010; Traynor et al. 2010).

In T. cruzi epimastigotes (Y strain), P-glycoprotein is encoded by two genes, \textit{TcPGP1} (Torres et al. 1999) and \textit{TcPGP2} (Dallagiovanna et al. 1996); both of these genes are presented as a single copy. However, little is known about the physiological role of this protein inside the parasite. It has been suggested that Pgp is involved in the trafficking of heme through the plasma membrane (Lara et al. 2007; Cupello et al. 2011).

Our data suggest that this ABCB1 efflux pump is involved in \textit{T. cruzi} drug resistance. It was demonstrated that the resistance to 2-Meotio and benznidazole in epimastigotes is associated with Pgp efflux activity, Pgp ATPase activity, and overexpression of the \textit{TcPGP1} and \textit{TcPGP2} genes. We also observed that cross-resistance occurs between the studied compounds and some Pgp modulators. These findings are in agreement with the MDR phenotype mediated by Pgp (Ambudkar et al. 1999). Moreover, considering that ATP binding and hydrolysis are recognized as essential conditions for the drug transport activity of Pgp (Horio et al. 1988; Scarborough 1995), the ability of both 2-Meotio and Bz to stimulate Pgp ATPase activity suggests that these compounds are Pgp

![Graph](image)

**Fig. 4** The effect of various concentrations of 2-Meotio or Bz on recombinant human Pgp ATPase activity (a). Pgp ATPase activity in the membrane fraction of Parental and M15 lines (b) or parental and B15 lines (c). The basal Pgp ATPase activity was calculated based on the difference between ATPase activity in the untreated sample and in the presence of cyclosporin A (CsA; 100 μM). The effect of 2-Meotio (71.7 μM) (b) or Bz (182.1 μM) (c) on Pgp ATPase activity was calculated based on the difference in ATPase activity in the presence of each compound alone (Bz or 2-Meotio) and the compound plus CsA (Bz+CsA or 2-Meotio+CsA). The results are expressed as nanomoles of ATP consumed in the reaction. *Asterisk*, significant difference for the comparison of basal ATP consumption between the parental line and the lines M15 (b) or B15 (c). **Double asterisk**, significant difference for the comparison of ATP consumption with and without treatment with 2-Meotio for the M15 line (b) or with Bz for the B15 line (c).

![Graph](image)

**Fig. 5** Relative gene expression of the \textit{TcPGP 1} and \textit{TcPGP2} genes in the parental and resistant lines of \textit{T. cruzi} quantified using real-time PCR. The values were normalized to the level of the β-actin gene and expressed as arbitrary units. The values shown are the mean±SD of three experiments performed in triplicate. *Asterisk*, relative gene expression was compared between M15 and parental lines, or B15 and parental lines. Differences between the values were considered significant when the increase in the gene expression was at least 1.5-fold higher.
substrates. Additionally, this is the first study to describe Pgp efflux activity and Pgp ATPase activity in T. cruzi, and this finding may contribute to an improved understanding of the biochemical properties of Pgp in this parasite.

Considering that the resistance phenotype was maintained throughout the entire parasite life cycle, an association between Pgp and drug resistance in the other developmental forms of T. cruzi can be proposed. Dallagiovanna et al. (1996) identified the gene TcPGP2 not only in epimastigote forms but also in intracellular amastigotes. However, the TcPGP1 gene has been studied only in the epimastigotes of T. cruzi (Torres et al. 1999). For this reason, its identification in the trypomastigote and amastigote forms should be investigated.

Despite the participation of Pgp in the common drug resistance mechanism between lines M15 and B15, these lines differed in the stability of the resistance phenotype in the absence of drug, most likely due to differences in the overall pattern of protein expression. This fact supports the existence of more than one mechanism that act in concert to provide drug resistance in T. cruzi. Studies regarding drug resistance to Bz have reported the participation of proteins associated with parasite metabolism (Portal et al. 2008; Campos et al. 2009) and antioxidant defense (Nogueira et al. 2009; Murta et al. 2008). Alterations in the expression of proteins related to drug metabolism have also been observed (Murta et al. 2006; Mejia-Jaramillo et al. 2011; Mejia et al. 2012). However, an association between Pgp expression and drug resistance has not been found (Murta et al. 2001). Nevertheless, some authors suggest that the in vivo and in vitro resistance to Bz operate through different mechanisms (Andrade et al. 2008; Villarreal et al. 2005). Until now, the existence of a common drug resistance mechanism has not been described either inside each genetic cluster of T. cruzi or among natural and laboratory-selected resistant lines (Dos Santos et al. 2008).

Interestingly, it was demonstrated that the first generation Pgp inhibitors cyclosporin A and verapamil were able to revert drug resistance to 2-Meotio and Bz in T. cruzi. Similar results have been described by Neal et al. (1989) who observed that co-treatment with nifurtimox and verapamil effectively reversed resistance to nifurtimox in the T. cruzi X10 clone in vitro. Thus, one approach that might be explored for the treatment of Chagas disease is to use a combination of drugs with Pgp reversal agents to prevent the emergence of the Pgp-mediated MDR phenotype. Clinical trials using Pgp reversal agents have been performed to overcome drug resistance in cancer cell lines (Sonneveld et al. 2001; Morjani and Madoulet 2010). Second-, third-, and fourth-generation Pgp inhibitors have been investigated; the last group is considered the most promising because drugs in this group exhibit higher affinity to Pgp and lower toxicity to normal mammal cells (Palmeira et al. 2012).

**Conclusions**

Inducing in vitro resistance to benznidazole in the Y strain of T. cruzi provided an additional model to not only study the characteristics of the resistance phenotype but also evaluate the effect of new compounds on this parasite. Furthermore, our data suggest that the Pgp efflux pump plays a role in T. cruzi drug resistance. Knowledge of the mechanism of drug resistance in T. cruzi may be helpful for further studies that focus on new drug targets and drug associations aimed at improving the treatment of Chagas disease.

**Appendix**

Fig. 6 The effects of verapamil, AEO solution, and cyclosporin A on recombinant human Pgp membrane. *Description of data:* Standardization of the assay, confirming that verapamil stimulates, cyclosporin A inhibits, and the AEO solution has no effect on Pgp ATPase activity. The effect of these agents on ATP consumption was compared with basal ATP consumption (which was measured based on the difference between ATP consumption in the presence and absence of sodium orthovanadate, a Pgp ATPase activity inhibitor).
Fig. 7 The effect of 2-Meotio and Bz on Pgp ATPase activity in the membrane fraction of parental and resistant T. cruzi lines. Description of data: To confirm the results observed in Fig. 4b, c, thereby overcoming the problem caused by other ATPases contributing to the activity measured in the membrane fractions of T. cruzi, we evaluated the consumption of ATP in the membrane fractions in the presence of non-Pgp ATPase inhibitors (AEO solution: sodium azide (inhibits F-type ATPase), ouabain (inhibits Na+K+ATPase) and EGTA (inhibits Ca+2 ATPase), together with verapamil (a well-known Pgp ATPase activity stimulator)]. The figure shows the concentration of ATP (nanomoles) not consumed. Significant differences for the comparison of basal ATPase activity between parental and resistant lines (asterisk) alone and (double asterisk) in the presence of the compounds 2-Meotio (a) or Bz (b).
