We investigate a Boltzmann gas in equilibrium with its center of mass moving on a circular geodesics in the Schwarzschild field. As a consequence of Tolman’s law we find that a central comoving observer measures oscillations of the temperature and of other thermodynamic quantities with twice the frequencies that are known from test-particle motion. We apply this scheme to the gas dynamics in the gravitational fields of the planets of the solar system as well as to strong-field configurations of neutron stars and black holes.

I. INTRODUCTION

Relativistic gas theory started as early as 1911 with the work of Jüttner [1] who derived the one-particle equilibrium distribution function for a Boltzmann gas. The covariant form of Boltzmann’s equation was obtained by Lichnerowicz and Marrot [2]. Equilibrium conditions for a relativistic gas were shown to imply the existence of a timelike Killing vector [3]. One of the consequences is Tolman’s law [4, 5] and another one is Klein’s law [6].

General relativistic gaseous fluids are of interest in cosmology and astrophysics. In many occasions the material content of the Universe is modeled in fluid dynamical terms. Then it is the energy-momentum tensor of the fluid which appears on the right-hand side of Einstein’s equations and determines the gravitational field. In an astrophysical context it is also the behavior of a gas on a given gravitational background which is important. The probably most interesting case here is the accretion of (gaseous) matter towards compact objects like black holes. An example are the observed high-frequency quasi-periodic oscillations in the fluxes from X-ray binaries which are supposed to be of general-relativistic origin [7–10].

Any gas-dynamical analysis starts by establishing the relevant equilibrium configurations of the system under consideration. For a Boltzmann gas one distinguishes local equilibrium from global equilibrium. The former relies on the mere equilibrium structure of the one-particle distribution function, the latter adds conditions on the quantities of this structure, in particular the already mentioned existence of a timelike Killing vector, equivalent to a stationarity condition for the metric. Generally, a global equilibrium is therefore incompatible with an expanding Universe, while local equilibrium states of the cosmic substratum are suitable starting points in standard cosmology.

The present paper is devoted to a global equilibrium configuration on the background of the static Schwarzschild metric. We consider a Boltzmann gas with its center of mass moving on a circular geodesics of this metric and we study the equilibrium thermodynamics of this system as seen by a comoving observer on the geodesics. While this is clearly an idealized situation, we hope that it may capture some typical features and serve as a starting point for more realistic problems in astrophysics where either the equilibrium hypothesis or the circular geodesic nature of the worldline or both are generalized.

The lowest-order gravitational effects that a freely falling observer can detect locally are conveniently described with the help of Fermi normal coordinates. These coordinates are Minkowskian on the geodesics while gravitation at lowest order manifests itself in quadratic corrections in the spacelike geodesic distance, orthogonal to the observer’s timelike trajectory. We apply a description of this type to the gas motion, admitting additionally a pure spatial rotation. This corresponds to using a “proper reference” frame (cf. [11]) up to second order. Fixing this frame determines, via Tolman’s law [4, 5], the temperature profile of the gas as measured by a central, geodesic observer. It turns out that the comoving observer measures oscillations of the temperature and other thermodynamic quantities with frequencies that are double the frequencies known from test-particle motion in the Schwarzschild field.

The structure of the paper is as follows. In Sec. III we recall basic properties of the Boltzmann equation for the one-particle distribution function and its equilibrium solution. Section IV is devoted to the corresponding equilibrium conditions. On this basis Tolman’s and Klein’s laws are derived in Sec. V. Section VI reviews the circular test particle motion in the Schwarzschild field. Fermi normal tetrads are introduced and discussed in Sec. VII on the basis of which the temperature profile is obtained in Sec. VIII. With the help of the equation of geodesic deviation we reproduce in Sec. IX the basic linear system which describes oscillatory motions around the central
geodesics. The corresponding oscillation of the temperature and the other thermodynamic quantities are discussed in Sec. [IX]. Sec. [X] summarizes our results.

II. BOLTZMANN EQUATION AND EQUILIBRIUM DISTRIBUTION FUNCTION

The particles of a relativistic gas in a Riemannian space with metric tensor $g_{\mu\nu}$ are characterized by the space-time coordinates $(x^\mu) = (ct, x)$ and momenta $(p^\mu) = (p^0, \mathbf{p})$. The particles have rest mass $m$ and due to the mass shell condition $g_{\mu\nu}p^\mu p^\nu = -m^2c^2$ a state of the relativistic gas is described by the one-particle distribution function $f(\mathbf{x}, \mathbf{p}, t)$ in the phase space spanned by the space-time and three momenta coordinates. The distribution function is defined in such a way that $f(\mathbf{x}, \mathbf{p}, t)d^3xd^3p$ gives at time $t$ the number of particles in the volume element $d^3xd^3p$.

The evolution of the one-particle distribution function in the phase space is governed by the Boltzmann equation, which in the presence of gravitational fields, reads (see e.g. [12])

$$p^\mu \frac{\partial f}{\partial x^\mu} - \Gamma^\rho_{\mu\nu} p^\mu p^\nu \frac{\partial f}{\partial p^\rho} = Q(f, f),$$

(1)

where $\Gamma^\rho_{\mu\nu}$ denote the Christoffel symbols and $Q(f, f)$ is the collision operator of the Boltzmann equation. In equilibrium $Q(f, f)$ vanishes and as a consequence the one-particle distribution function for a classical gas becomes the Maxwell-Juttner distribution function:

$$f^{(0)} = \frac{n}{4\pi kT m^2 cK_2(\zeta)} \exp\left(-\frac{U^\mu p_\mu}{kT}\right).$$

(2)

Here $n$, $T$ and $U^\nu$ refer to the particle number density, temperature and four-velocity (with $U^\mu U_\mu = -c^2$), respectively. Furthermore, $k$ is the Boltzmann constant, $c$ the light speed and

$$K_n(\zeta) = \left(\frac{\zeta}{2}\right)^n \frac{\Gamma(1/2)}{\Gamma(n+1/2)} \int_1^{\infty} e^{-\zeta y} (y^2 - 1)^{n-1/2} dy$$

(3)

denote modified Bessel functions of the second kind with $\zeta = mc^2/kT$. The parameter $\zeta$ gives the ratio of the rest energy $mc^2$ of a gas particle and the thermal energy of the gas $kT$. The non-relativistic limiting case corresponds to $\zeta \gg 1$, while the ultra-relativistic one corresponds to $\zeta \ll 1$.

From the knowledge of the equilibrium distribution function (2) we may evaluate the equilibrium energy-momentum tensor $T^{\mu\nu}$ and the equilibrium entropy four-flow $S^\mu$ defined by

$$T^{\mu\nu} = c \int p^\mu p^\nu f^{(0)} \sqrt{-g} \frac{d^3p}{p_0} = \frac{en}{c^2} U^\mu U^\nu + pg^{\mu\nu},$$

(4)

$$S^\mu = -k c \int p^\mu f^{(0)} \ln f^{(0)} \sqrt{-g} \frac{d^3p}{p_0} = n s U^\mu,$$

(5)

and obtain the following expressions for the energy per particle $e$, the pressure $p$ and the entropy per particle $s$:

$$e = mc^2 \left(\frac{K_3(\zeta)}{K_2(\zeta)} - \frac{1}{\zeta}\right), \quad p = nkT,$$

(6)

$$s = k \left\{ \ln \left(\frac{en}{4\pi kT m^2 cK_2(\zeta)}\right) + \zeta \frac{K_3(\zeta)}{K_2(\zeta)} \right\}.$$  

(7)

Another thermodynamic potential is the Gibbs function per particle $g = e - TS + p/n$, which can be identified with the chemical potential $\mu$:

$$\mu \equiv g = kT \left[ \ln \left(\frac{en}{4\pi kT m^2 cK_2(\zeta)}\right) \right].$$

(8)

The equilibrium distribution function (2) can also be expressed in terms of the chemical potential $\mu$ as

$$f^{(0)} = \exp\left(\frac{\mu}{kT} - 1 - \frac{U^\nu p_\nu}{kT}\right).$$

(9)

III. EQUILIBRIUM CONDITIONS

While the right-hand side of the Boltzmann equation (1) vanishes identically for the equilibrium distribution function, its left-hand side imposes restrictions on the fields that appear in this distribution function. Indeed, from the insertion of (1) into (1) it follows the polynomial equation in the momentum four-vector $p^\mu$:

$$p^\nu \partial_\nu \left[ \frac{\mu}{kT} \right] - \frac{1}{2} p^\mu p^\nu \left[ \frac{U_\mu}{kT} \right]_{\nu} + \left[ \frac{U_\nu}{kT} \right]_{\mu} = 0.$$  

(10)

Since the above equation is valid for all values of $p^\mu$ this implies that

$$\partial_\nu \left[ \frac{\mu}{kT} \right] = 0, \quad \left[ \frac{U_\mu}{kT} \right]_{\nu} + \left[ \frac{U_\nu}{kT} \right]_{\mu} = 0,$$

(11)

provided the relativistic gas particles have non-vanishing rest masses. Equation (11) is the so-called Killing equation, which can be rewritten as

$$U_{\mu;\nu} + U_{\nu;\mu} - \frac{1}{T} (T_{\nu} U_{\mu} + T_{\mu} U_{\nu}) = 0.$$  

(12)

From the contractions of the Killing equation (12) we get the relations

$$\dot{T} = 0, \quad \dot{U}_\mu + \frac{c^2}{T} \nabla_\mu T = 0,$$

(13)

respectively, thanks to $U^{\nu} U_{\nu} = 0$. Here

$$\dot{T} \equiv U^{\mu} \partial_\mu T, \quad \dot{U}_\mu \equiv U^{\nu} U_{\mu;\nu}, \quad \nabla T \equiv h^{\mu}_{\mu} T_{,\nu},$$

(14)

where $h_{\mu\nu} = g_{\mu\nu} + c^{-2} U_{\mu} U_{\nu}$. Equations (13) may be interpreted as follows: in equilibrium a gas must have a stationary temperature and its acceleration must be counterbalanced by a spatial temperature gradient. We call attention to the fact that (13) is not compatible with a geodesic fluid motion which would require that $\dot{U} = 0$. We shall return to this point in Section [VIII].

Furthermore, the contraction of (12) by $g^{\mu\nu}$ leads to the vanishing expansion scalar $U_{\mu;\mu} = 0$. 
IV. TOLMAN AND KLEIN LAWS

In order to derive Tolman’s law [4, 5] let us consider a fluid at its rest frame so that the spatial components of the four-velocity vanish and

$$ (U^\mu) = \left( \frac{c}{\sqrt{-g_{00}}} \, 0 \right). $$

(15)

In this case the acceleration term becomes

$$ \dot{U}^\mu = -\frac{c^2}{g_{00}}\Gamma^\mu_{00} = \frac{c^2}{2g_{00}} g^{\mu\nu} g_{0\nu}, $$

(16)

where the last equality is valid provided that the metric tensor components do not depend on time.

From this expression we infer that $\phi$ and $\varphi$ are cyclic coordinates so that the corresponding generalized momenta $p_\varphi$ and $p_0$ are conserved and read

$$ p_\varphi = \frac{\partial \mathcal{L}}{\partial (d\varphi/d\tau)} = m r^2 \frac{d\varphi}{d\tau} = l, \quad (21) $$

$$ p_0 = \frac{\partial \mathcal{L}}{\partial (dx^0/d\tau)} = -m \left( 1 - \frac{2M}{r} \right) \frac{dx^0}{d\tau} = -\frac{E}{c}, \quad (22) $$

Above, $l$ and $E$ denote the angular momentum and the energy of the particle, respectively.

A circular orbit of constant radius $r$ is characterized by

$$ \tilde{E}^2 = \left( 1 - \frac{2M}{r} \right) \left[ 1 + \frac{\tilde{\ell}^2}{r^2} \right], $$

(23)

thanks to (19), (21) and (22). Here we have introduced the energy per unit mass $\tilde{E} = E/mc^2$ and the angular momentum per unit mass $\tilde{\ell} = l/mc.$

The motion of the test particle is obtained from (19), (21) and (22) and can be written as (see, e.g., [11])

$$ \left( \frac{dr}{d\tau} \right)^2 + \tilde{V}^2 = \tilde{E}^2, $$

(24)

where $\tilde{V}$ denotes the effective potential

$$ \tilde{V} = \left( 1 - \frac{2M}{r} \right) \left[ 1 + \frac{\tilde{\ell}^2}{r^2} \right]. $$

(25)

The possible circular orbits are found by searching the extreme values of the effective potential $\tilde{V}$, yielding

$$ \tilde{\ell}^2 = \frac{M r^2}{r - 3M}, $$

(26)

Hence, a test particle of rest mass $m$ in orbital motion with $\vartheta = \pi/2$ is characterized by constant values of angular momentum per unit of mass (26) and energy per unit mass

$$ \tilde{E}^2 = \left( 1 - \frac{2M}{r} \right)^2 \frac{r}{r - 3M}, $$

(27)

thanks to (23) and (26).

Since $d\varphi/d\tau$ is given by (21) and the angular momentum by (26) it follows by integration that

$$ \varphi = \frac{1}{r} \sqrt{\frac{M}{r - 3M}} \tau \quad (28) $$

for a circular orbit of constant radius $r$. The corresponding angular frequency of the particle motion is

$$ \omega_\varphi = \omega_N \sqrt{\frac{r}{r - 3M}}, \quad \omega_N = \sqrt{\frac{GM}{r}}, $$

(29)

where $\omega_N$ is the Newtonian frequency in the limit for $r \gg M$.

If the particle is slightly displaced from the exact circular motion in radial direction, there exists another oscillation frequency which is given by half the second derivative of (25) combined with (26) which reads [19]

$$ \omega_r = \omega_N \sqrt{\frac{r - 6M}{r - 3M}}. $$

(30)

Obviously, both frequencies only coincide for $r \gg M$. Their difference gives rise to a precession of the particle motion within the orbital plane.

V. SCHWARZSCHILD METRIC

The Schwarzschild metric is

$$ ds^2 = -\left( 1 - \frac{2M}{r} \right) (dx^0)^2 + \frac{1}{1 - \frac{2M}{r}} dr^2 + r^2 (d\vartheta^2 + \sin^2 \vartheta d\varphi^2) = -c^2 d\tau^2, $$

(19)

where $M = GM/c^2$ and $G$ denotes the gravitational constant.

The Lagrangian of the orbital motion of a test particle with rest mass $m$ in the plane $\vartheta = \pi/2$ is

$$ \mathcal{L} = m \left[ \frac{1}{1 - \frac{2M}{r}} \left( \frac{dr}{d\tau} \right)^2 + r^2 \left( \frac{d\varphi}{d\tau} \right)^2 \right. $$

$$ \left. - \left( 1 - \frac{2M}{r} \right) \left( \frac{dx^0}{d\tau} \right)^2 \right]. $$

(20)

From this expression we infer that $\varphi$ and $x^0$ are cyclic coordinates so that the corresponding generalized momenta $p_\varphi$ and $p_0$ are conserved and read

$$ p_\varphi = \frac{\partial \mathcal{L}}{\partial (d\varphi/d\tau)} = m r^2 \frac{d\varphi}{d\tau} = l, \quad (21) $$

$$ p_0 = \frac{\partial \mathcal{L}}{\partial (dx^0/d\tau)} = -m \left( 1 - \frac{2M}{r} \right) \frac{dx^0}{d\tau} = -\frac{E}{c}. \quad (22) $$

(22)
The non-vanishing components of the curvature tensor for $\vartheta = \pi/2$ are:

$$R_{0101} = -\frac{2M}{r^3}, \quad R_{0202} = \frac{M}{r} \left( 1 - \frac{2M}{r} \right), \quad (31)$$

$$R_{1212} = -\frac{M}{r} \left( 1 - \frac{2M}{r} \right), \quad R_{2323} = 2Mr, \quad (32)$$

$$R_{0303} = R_{0202}, \quad R_{1212} = R_{1313}. \quad (33)$$

Here, the overbar denotes the original Schwarzschild coordinates according to \[13\].

**VI. FERMI NORMAL COORDINATES**

Now we suppose a rarefied gas, say, inside a spacecraft in circular orbit around an object with mass $M$ described by the Schwarzschild metric. The system under study is governed by the Schwarzschild metric, since the spacecraft and the gas do not have noteworthy contributions to the gravitational field. Let the center of mass of the gas move on a circular geodesic. An observer at the center of mass will conveniently use Fermi normal coordinates to describe local gravitational effects in the vicinity of the geodesics \[13\]. These are comoving, time-orthogonal coordinates with the center of mass at rest in the origin. The time coordinate is the proper time $\tau$ of the center on the geodesics. The spatial coordinates are orthogonal spacelike geodesics parametrized by the proper distance.

Quite generally, the components of the metric tensor up to the second order in the deviations from the geodesics in Fermi normal coordinates are \[13\]:

$$g_{00} = -1 - R_{000n}x^n x^m, \quad (34)$$

$$g_{01} = \frac{2}{3} R_{01m} x^m x^n, \quad (35)$$

$$g_{ij} = \delta_{ij} - \frac{1}{3} R_{ijmn} x^n x^m, \quad (36)$$

The curvature-tensor terms describe the lowest-order gravitational effects which a freely falling observer can measure locally. For the special case of circular geodesics in the Schwarzschild field a Fermi normal tetrad has been obtained in \[14\]:

$$\left( e^0_\alpha \right) = \left( \frac{\tilde{E}}{X}, 0, 0, \frac{\tilde{l}}{r^2} \right), \quad (37)$$

$$\left( e^1_\alpha \right) = \left( -\frac{\tilde{t}\sin\alpha\varphi}{r\sqrt{X}}, \frac{\sqrt{X} \cos\alpha\varphi}{r\sqrt{X}}, 0, -\frac{\tilde{E}\sin\alpha\varphi}{r\sqrt{X}} \right), \quad (38)$$

$$\left( e^2_\alpha \right) = \left( 0, 0, \frac{1}{r}, 0 \right), \quad (39)$$

$$\left( e^3_\alpha \right) = \left( \frac{\tilde{t}\cos\alpha\varphi}{r\sqrt{X}}, \frac{\sqrt{X} \sin\alpha\varphi}{r\sqrt{X}}, 0, \frac{\tilde{E}\cos\alpha\varphi}{r\sqrt{X}} \right). \quad (40)$$

In the above equations we have introduced the abbreviations:

$$\alpha = \sqrt{\frac{r - 3M}{r}}, \quad X = 1 - \frac{2M}{r}. \quad (41)$$

At some initial time $(e^0_\alpha)$ shows in radial direction and $(e^3_\alpha)$ shows in tangential direction. $(e^2_\alpha)$ is always perpendicular to the orbital plane. One realizes that on the circular geodesics

$$g_{\alpha\beta} \frac{\partial x^\alpha}{\partial \bar{x}^\mu} \frac{\partial x^\beta}{\partial \bar{x}^\nu} = \eta_{\mu\nu} \quad (42)$$

is valid, where $\eta_{\mu\nu}$ is the Minkowski metric. The tetrads are parallel transported along the circular geodesics,

$$\frac{D e^\beta_\alpha}{d\tau} = 0. \quad (43)$$

The non-vanishing components of the Riemann tensor in the Fermi normal coordinates are determined from

$$R_{\hat{\mu}\hat{\nu}\hat{\alpha}\hat{\beta}} = R_{\alpha\beta\mu\nu} e^\alpha_{\hat{\alpha}} e^\beta_{\hat{\beta}} e^\mu_{\hat{\mu}} e^n_{\hat{n}}. \quad (44)$$

Using \[40\] - \[43\] and \[41\] - \[46\] yields \[13, 16\]:

$$R_{0101} = -\frac{M[r + 3(r - 2M) \cos(2\alpha\varphi)]}{2(r - 3M)r^3}, \quad (45)$$

$$R_{0103} = -\frac{3M[r - 2M] \sin(2\alpha\varphi)}{2(r - 3M)r^3}, \quad (46)$$

$$R_{0202} = \frac{M}{(r - 3M)r^2}, \quad (47)$$

$$R_{0303} = -\frac{M[r - 3(r - 2M) \cos(2\alpha\varphi)]}{2(r - 3M)r^3}, \quad (48)$$

$$R_{0113} = \frac{3M^2 \sqrt{r - 2M} \cos(\alpha\varphi)}{(r - 3M)r^3}, \quad (49)$$

$$R_{0212} = -\frac{3M^2 \sqrt{r - 2M} \sin(\alpha\varphi)}{(r - 3M)r^3}, \quad (50)$$

Furthermore, the following relationships hold \[16\]:

$$R_{0313} = -R_{0212}, \quad R_{0223} = -R_{0113}, \quad R_{1212} = -R_{0303}, \quad R_{1313} = -R_{0202}, \quad R_{1223} = -R_{0103}, \quad R_{2323} = -R_{0011}. \quad (51) - (53)$$

Via $\varphi$ the components of $R_{\hat{\mu}\hat{\nu}\hat{\alpha}\hat{\beta}}$ depend on $\tau$. Moreover, because of the non-vanishing component $R_{0103}$ the second-order contribution to $g_{00}$ is not diagonal. A simpler structure can be obtained by performing a tetrad rotation around the $x^2$-direction characterized by

$$E^1 = e^1_1 \cos \alpha \varphi + e^1_3 \sin \alpha \varphi \quad (54)$$

Now $(E^0_1)$ always shows in radial direction and $(E^3_3)$ always shows in tangential direction. Explicitly

$$E^0_1 = \sqrt{\frac{r}{r - 3M}}, \quad E^3_3 = \frac{1}{r} \sqrt{\frac{M}{r - 3M}}, \quad (55)$$

$$E^1_1 = \left( 1 - \frac{2M}{r} \right)^{1/2}, \quad E^2_2 = \frac{1}{r}, \quad (56)$$

$$E^0_3 = \sqrt{\frac{Mr}{(r - 2M)(r - 3M)}}, \quad E^3_3 = \frac{1}{r} \sqrt{\frac{r - 2M}{r - 3M}}. \quad (57)$$
The tetrads \( \mathbf{e}_0 \) and \( \mathbf{e}_3 \) are unchanged. In this frame the curvature tensor components take a simpler form:

\[
R_{010} = -\frac{M}{r^3} 2r - 3M - R_{013},
\]

\[
R_{303} = \frac{M}{r^3} = -R_{1212},
\]

\[
R_{0113} = \frac{3M}{r^3} \sqrt{M(r - 2M)} = R_{0232},
\]

\[
R_{0202} = \frac{M}{r^3} r - 3M = -R_{1313}.
\]

The price to pay for this simplification is that the new tetrads are no longer parallel transported. Combining \( \frac{D\mathbf{e}_i}{d\tau} = 0 \) and \( \frac{D\mathbf{e}_3}{d\tau} = 0 \) in (53) results in

\[
\frac{D\mathbf{E}_i}{d\tau} = \sqrt{\frac{M}{r^3}} \mathbf{E}_3, \quad \frac{D\mathbf{E}_3}{d\tau} = -\sqrt{\frac{M}{r^3}} \mathbf{E}_1.
\]

The transformation describes a rotation with frequency \( \sqrt{\frac{M}{r^3}} \). As a result, there appear non-vanishing Christoffel symbols on the geodesics together with mixed space-time relations are (cf. [11, 17])

\[
\text{terms linear in } \omega \text{ and } g_{\beta\gamma} \text{ and only there, the equilibrium condition (13) is restricted to linear deviations from the central geodesics, our analysis includes the deviations up to second order. The relevant relations are (cf. [11, 17])}
\]

\[
\Gamma^a_{0n} = \epsilon_{m}^a \omega^m, \quad g_{06, n} = -\epsilon_{6mn} \omega^m.
\]

In our case

\[
\Gamma^1_{03} = \epsilon_{12} \omega = \omega, \quad \Gamma^3_{01} = -\epsilon_{31} \omega = -\omega.
\]

It follows that

\[
g_{01, 3} = -\epsilon_{132} \omega = \omega, \quad g_{03, 1} = -\epsilon_{312} \omega = -\omega.
\]

With \( \omega = \sqrt{\frac{M}{r^3}} \) we have

\[
g_{01} = \sqrt{\frac{M}{r^3}} x^3, \quad g_{03} = -\sqrt{\frac{M}{r^3}} x^1.
\]

Once we know the curvature tensor components in this new frame, we can obtain the components of the metric tensor up to second order in the deviations. In this work we focus on the component \( g_{00} \) since this is the component which appears in Tolman’s and Klein’s laws. It reads

\[
g_{00} = -1 + \frac{M}{r^3} \left[ 2r - 3M \left( x^1 \right)^2 - \frac{r}{r - 3M} \left( x^2 \right)^2 - \left( x^3 \right)^2 \right].
\]

VII. THE TEMPERATURE PROFILE

Now we combine the metric structure (57) with Tolman’s relation (13). As a result we obtain the parabolic temperature profile in the vicinity of the central geodesics

\[
T = \frac{T_0}{\sqrt{-g_{00}}} \approx T_0 \left\{ 1 + \frac{M}{2r^3} \left[ \frac{2r - 3M}{r - 3M} \left( x^1 \right)^2 - \frac{r}{r - 3M} \left( x^2 \right)^2 - \left( x^3 \right)^2 \right] \right\},
\]

where \( T_0 \) is the constant equilibrium temperature on the central geodesics. Obviously, the temperature variations are different in different directions away from the geodesic. The parabolic structure of the temperature distribution implies that the spatial gradient of the temperature is linear in the deviation from the central geodesic. Consequently, the temperature gradient vanishes on the central geodesic itself. Therefore, on this geodesic, and only there, the equilibrium condition (13) consistently reduces to the equation \( \dot{U}^\mu = 0 \) for geodesic fluid motion. Away from the central circular geodesic the equilibrium fluid motion is nongeodesic. However, since the deviation is linear in the distance the situation simplifies as we shall discuss in the following section.

VIII. GEODESIC DEVIATION

Apparently, the second equilibrium condition (13) is not compatible with a geodesic motion \( \dot{U}^\mu = 0 \) away from the central circular geodesic. But since the terms that “perturb” the geodesic behavior are linear in the distance, the equation of geodesic deviation turns out to be applicable for our problem. The reason is that these perturbing terms lead to higher-order corrections for the geodesic deviation. In the following we demonstrate this in some detail.

Quite generally, for a vector \( \xi^\alpha \) orthogonal to the geodesics the equation for the geodesic deviation is

\[
\frac{D^2 \xi^\alpha}{d\tau^2} + R^\alpha_{\beta\gamma\lambda} U^\beta U^\gamma \xi^\lambda = 0,
\]

where the explicit form of the first term of the above equation reads

\[
\frac{D^2 \xi^\alpha}{d\tau^2} = D^2 \xi^\alpha + \Gamma^\alpha_{\beta\gamma} \xi^\beta \frac{dx^\beta}{d\tau} \frac{dx^\gamma}{d\tau} + 2 \Gamma^\alpha_{\beta\gamma} \xi^\beta \frac{dx^\gamma}{d\tau} \frac{dx^\lambda}{d\tau} + \Gamma^\alpha_{\beta\gamma} \xi^\beta \frac{dx^\gamma}{d\tau} \frac{dx^\lambda}{d\tau}.
\]

Let us analyze the underlined term in (70). Writing the second equilibrium condition (13) as

\[
\dot{U}^\gamma = \frac{DU^\gamma}{d\tau} = \frac{D^2 x^\gamma}{d\tau^2} = \frac{c^2}{T} \nabla^\gamma T,
\]

and

\[
\frac{d^2 x^\gamma}{d\tau^2} = -\Gamma_{\kappa\lambda} U^\kappa U^\lambda - \frac{c^2}{T} \nabla^\gamma T,
\]
the underlined term is
\[ \Gamma^\alpha_{\beta\gamma} \xi^\beta \frac{d^2 x^\gamma}{dt^2} = -\Gamma^\alpha_{\beta\gamma} \xi^\beta \left[ \Gamma^\gamma_{\kappa\lambda} U^\kappa U^\lambda + \frac{\xi^2}{T} \nabla^\gamma T \right]. \] (73)

Since \( \nabla^\gamma T \) is linear in the distance and the entire term is already linear in \( \xi^\beta \), the temperature gradient gives rise to a second-order contribution. Hence, up to linear order we get the relationship
\[ \Gamma^\alpha_{\beta\gamma} \xi^\beta \frac{d^2 x^\gamma}{dt^2} = -\Gamma^\alpha_{\beta\gamma} \xi^\beta \Gamma^\gamma_{\kappa\lambda} U^\kappa U^\lambda. \] (74)

Furthermore, in the terms that multiply \( \xi^\alpha \) we may approximate \( (15) \) by \( (U^\mu) = (c, 0) \) since in our metric \( g_{00} = -1 + O(x^2) \) and any correction to \( g_{00} = -1 \) would lead to higher-order terms. In this case \( (74) \) together with \( (73) \) yields
\[ \frac{D^2 \xi^\alpha}{dt^2} = \frac{d^2 \xi^\alpha}{dt^2} + c^2 \Gamma^\alpha_{\beta\gamma} \xi^\beta + 2c \Gamma^\alpha_{\beta\gamma} \frac{dx^\beta}{dt} = -c^2 \Gamma^\alpha_{\beta\gamma} \xi^\beta \Gamma^\gamma_{\kappa\lambda} x^\kappa x^\lambda + c^2 \Gamma^\alpha_{\beta\gamma} \xi^\beta \rho^\gamma \xi^\rho, \] (75)

while the second term in \( (73) \) reduces to
\[ \mathcal{R}^\alpha_{\gamma\mu\nu} U^\gamma U^\nu \xi^\mu = c^2 g^{\alpha\beta} R_{\beta\rho\mu\nu} \xi^\mu. \] (76)

Now we identify the spatial components of \( \xi^\alpha \) with the components \( x^\alpha \) of our tetrad system and obtain from \( (69) \) together with \( (73) \) and \( (75) \) the following form of the equation for the geodesic deviation:
\[ \frac{d^2 x^\alpha}{dt^2} + 2c \Gamma^\alpha_{\beta\gamma} \frac{dx^\beta}{dt} = c^2 \Gamma^\alpha_{\beta\gamma} x^\beta \Gamma^\gamma_{\kappa\lambda} x^\kappa x^\lambda + c^2 \Gamma^\alpha_{\beta\gamma} \Gamma^\gamma_{\kappa\lambda} x^\kappa x^\lambda + c^2 g^{\alpha\beta} R_{\beta\rho\mu\nu} x^\mu = 0. \] (77)

Note that the time derivative of the Christoffel symbols vanishes, since the metric is static. The temporal part of the equation for the geodesic deviation is identically satisfied.

Consequently, by taking into account the expressions for the components of the Riemann tensor \( (58) - (61) \) and those for the Christoffel symbols \( (61) \), the system of equations in linear order reduces to
\[ \frac{d^2 x^1}{dt^2} - 2c \sqrt{\frac{M}{r^3}} \frac{dx^3}{dt} - 3c^2 \frac{M}{r^3} r - 2M \frac{dx^1}{dt} = 0, \] (78)
\[ \frac{d^2 x^2}{dt^2} + 2c \frac{M}{r^3} r - 3M \frac{dx^2}{dt} = 0, \] (79)
\[ \frac{d^2 x^3}{dt^2} + 2c \sqrt{\frac{M}{r^3}} \frac{dx^1}{dt} = 0. \] (80)

The system \( (78) - (80) \) coincides with the system derived for the motion of a test particle in \( (18) \).

Equation \( (79) \) decouples from the other equations and describes oscillations in the component \( x^2 \). The real solution can be written as
\[ x^2 = x_0^2 \sin(\Omega \tau), \quad \text{with} \quad \Omega = \sqrt{\frac{GM}{r^3}} \frac{r}{r - 3M}. \] (81)

where \( \Omega \) denotes the frequency of the harmonic motion of the \( x^2 \) component. This frequency coincides with the orbital frequency \( \omega_2 \) in \( (29) \). But in the present context it characterizes an oscillation perpendicular to the orbital plane.

The coupled system of equations \( (78) \) and \( (80) \) for \( x^1 \) and \( x^3 \) has solutions which also describe oscillations in these components. The real solutions can be written as
\[ x^1 = x_0^1 \sin(\omega \tau), \] (82)
\[ x^3 = 2 \sqrt{\frac{r - 6M}{r - 3M}} x_0^3 \cos(\omega \tau). \] (83)

Here the oscillation frequency is
\[ \omega = \sqrt{\frac{GM}{r^3}} \frac{r - 6M}{r - 3M}. \] (84)

This frequency coincides with the radial frequency \( \omega_r \) in \( (30) \). But now it characterizes oscillations in tangential direction as well. Hence, in the \((x^1, x^3)\) plane the motion is described by an ellipse. Different from the situation in terms of Schwarzschild coordinates in Sec. \( \text{VI} \) there is no precession in the orbital plane for a comoving observer.

As already discussed in Sec. \( \text{V} \) the frequencies \( \Omega \) and \( \omega \) only coincide in the limit \( M \ll r \) where
\[ \omega_N = \Omega_N = \sqrt{\frac{GM}{r^3}}. \] (85)

Their ratio is given by
\[ \frac{\omega}{\Omega} = \sqrt{1 - \frac{6M}{r}}. \] (86)

Oscillations with frequencies \( \Omega \) and \( \omega \) have been derived for geodesic particle motion in the Schwarzschild field by Shirokov \( (18) \). The new feature here is that, via Tolman’s relation, these frequencies are also relevant for the gas temperature and other thermodynamic quantities as will be discussed in the following section.

As pointed out in \( (18) \), the first-order corrections to the Newtonian frequency are different for \( \Omega \) and \( \omega \):
\[ \omega \approx \omega_N \left( 1 - \frac{3M}{2r} \right), \quad \Omega \approx \Omega_N \left( 1 + \frac{3M}{2r} \right). \] (87)

On the other hand, stable circular orbits only exist for \( r > 6M \) \( (19) \). In the limit \( r \to 6M \) one has \( \omega \to 0 \) and \( \Omega \to \sqrt{2}\Omega_N \). The oscillations are frozen in in the \((x^1 - x^3)\) plane, while they continue with the frequency \( \sqrt{2}\Omega_N \) in the \((x^3)\) plane. In the interval \( 3M < r < 6M \) there exist unstable circular trajectories. Since \( \omega \) becomes imaginary in this region, there are exponential instabilities in the \((x^1 - x^3)\) plane. The oscillation frequency in the \((x^2)\) direction increases to very large values as the limit \( r = 3M \) is approached.
IX. THERMODYNAMIC PROPERTIES IN CIRCULAR GEODESIC MOTION

In this section we shall analyze the thermodynamic fields of a rarefied gas as measured by an observer in circular geodesic motion.

A. Temperature oscillations

From (68) with (81) – (84) we obtain the temperature profile

\[ \frac{T - T_0}{T_0} = \Delta(\tau) = \frac{M}{2r^3} \left\{ (x_0^1)^2 \left[ A \sin^2(\omega \tau) - B \cos^2(\omega \tau) \right] - C \sin^2(\Omega \tau) \right\}, \]  

(88)

where we have introduced the abbreviations

\[ A \equiv \frac{2r - 3M}{r - 3M}, \quad B \equiv \frac{4r - 3M}{r - 6M}, \quad C \equiv \frac{r}{r - 3M}. \]  

(89)

Since the solutions of the system (78) – (80) enter quadratically in the temperature profile, the oscillation frequencies are doubled. The explicit expression is

\[ \Delta(\tau) = \frac{M}{4r^3} (x_0^1)^2 \left\{ (A - B) - (A + B) \cos(2\omega \tau) - C \left( \frac{x_0^2}{x_0^1} \right)^2 \cos(2\Omega \tau) \right\}. \]  

(90)

The temperature field oscillates in the \((x^1, x^3)\) plane with the frequency \(2\omega\) and different amplitudes, while in the \(x^2\) direction the oscillation frequency is \(2\Omega\). In the Newtonian limit we have

\[ \Delta_N(\tau) = -\frac{M}{4r^3} (x_0^1)^2 \left\{ 2 + \left( \frac{x_0^2}{x_0^1} \right)^2 \right\} \cos \left( \frac{GM}{r^3} \tau \right). \]  

(91)

The lowest-order general relativistic corrections modify the amplitudes according to

\[ A - B \approx -2 - 9 \frac{M}{r}, \quad A + B \approx 6 + 15 \frac{M}{r}, \quad C \approx 1 + 3 \frac{M}{r}. \]  

(92)

The more interesting effect is a modulation of the frequencies:

\[ \cos(2\omega \tau) \approx \cos \left( 2\omega_N \left( 1 - \frac{3M}{2r} \right) \tau \right), \]  

(93)

\[ \cos(2\Omega \tau) \approx \cos \left( 2\Omega_N \left( 1 + \frac{3M}{2r} \right) \tau \right). \]  

(94)

It follows that the oscillation periods are different in different directions. Equivalently, this modulation can be expressed as

\[ \cos(2\omega \tau) \approx \cos \left( 2\omega_N \tau \right) \cos \left( 3\frac{M}{r} \omega_N \tau \right) \]  

\[ + \sin(2\omega N \tau) \sin \left( 3\frac{M}{r} \omega_N \tau \right) \]  

(95)

and

\[ \cos(2\Omega \tau) \approx \cos \left( 2\Omega_N \tau \right) \cos \left( 3\frac{M}{r} \Omega_N \tau \right) \]  

\[ - \sin(2\Omega_N \tau) \sin \left( 3\frac{M}{r} \Omega_N \tau \right). \]  

(96)

The Newtonian oscillations with frequency \(2\omega_N = 2\Omega_N\) are modulated by the very small frequency \(3\frac{M}{r} \omega_N\).

At lowest order, the frequency difference \(\Delta \omega\) is

\[ \Delta \omega = 2 (\Omega - \omega) = 6 \frac{(GM)^{3/2}}{c^2 r^{5/2}}. \]  

(97)

The deviations from Newtonian behavior are more drastic for strong fields. Let us consider the case \(r = 7M\) which is well in the range of stable circular orbits. In this case

\[ A = \frac{11}{4}, \quad B = 16, \quad C = \frac{7}{4}. \]  

(98)

and the frequencies \(\omega\) and \(\Omega\) become

\[ \omega = \frac{\omega_N}{2} \quad \text{and} \quad \Omega = \frac{\sqrt{7}}{2} \omega_N, \]  

(99)

respectively. The frequency \(\omega\) is considerably smaller than the Newtonian frequency, while \(\Omega\) is considerably larger. The temperature field oscillates with \(2\omega = \omega_N\) and \(2\Omega = \sqrt{7} \Omega_N\). The oscillation periods differ by a factor of \(\sqrt{7}\). The frequency difference is

\[ \Delta \omega = \left( \sqrt{7} - 1 \right) \omega_N \approx 1.65 \omega_N. \]  

(100)

Likewise we obtain the values for \(r = 10M\):

\[ A = \frac{17}{4}, \quad B = 7, \quad C = \frac{10}{7}. \]  

(101)

\[ \omega = \frac{2}{\sqrt{7}} \omega_N, \quad \Omega = \frac{\sqrt{7}}{2} \omega_N. \]  

(102)

Here, we find

\[ \Delta \omega \approx 0.88 \omega_N. \]  

(103)

Interestingly, the ratio between the frequencies for \(r = 10M\) is \(\Omega/\omega = \sqrt{2.5} \approx 1.58\) which is close to the frequently observed twin-peak ratio \(3/2\) in the power spectra of X-ray binaries \(7\).

As already mentioned, when \(r\) approaches \(6M\) the frequency \(\omega\) approaches zero while the coefficient \(B\) diverges. This indicates the onset of an instability. In the range \(3M < r < 6M\) the coefficient \(B\) is negative and we have an imaginary \(\omega\), indicating an exponential instability. As \(r\) approaches \(3M\), the oscillation frequency in \(x^2\) direction becomes infinitely large.
B. Thermodynamic functions at equilibrium

From Klein’s law \( \mu \sqrt{-\gamma_{00}} = \text{constant} \) it follows that the chemical potential has the same oscillatory character as the temperature field, namely,

\[
\frac{\mu - \mu_0}{\mu_0} = \Delta(\tau). \tag{104}
\]

The energy per particle (6) is only a function of the temperature so that we can write

\[
\frac{e - e_0}{kT_0} = c_v^0 \frac{\partial e}{\partial T} \bigg|_{T_0} = k\zeta^2 \left[ 1 + \frac{5}{\zeta_0} K_3(\zeta_0) - \frac{1}{\zeta_0^2} \right]. \tag{105}
\]

where \( c_v \) is the heat capacity per particle at constant volume

\[
c_v^0 = \left. \frac{\partial e}{\partial T} \right|_{T_0} = k\zeta^2 \left[ 1 + \frac{5}{\zeta_0} K_3(\zeta_0) - \frac{1}{\zeta_0^2} \right]. \tag{106}
\]

According to (8) and (11), the particle number density \( n \) is only a function of the temperature:

\[
n = 4\pi m^2 c K_2(\zeta_0) \frac{\omega_0}{\zeta} e^{\omega_0/kT_0} = 4\pi m^2 c K_2(\zeta_0) \frac{\omega_0}{\zeta} e^{\omega_0/kT_0}, \tag{107}
\]

and we may express it as

\[
n = n_0 + \frac{\partial n}{\partial T} \bigg|_{T_0} (T - T_0). \tag{108}
\]

From the above equation and (8) and (104) we obtain the oscillations of the particle number density in the vicinity of the circular geodesics:

\[
\frac{n - n_0}{n_0} = \left[ \zeta_0 \frac{K_3(\zeta_0)}{K_2(\zeta_0)} - 1 \right] \Delta(\tau). \tag{109}
\]

The oscillations of the pressure field follow from the equation of state \( p = nkT \), (8), (109) and read

\[
p - p_0 = \zeta_0 \frac{K_3(\zeta_0)}{K_2(\zeta_0)} \Delta(\tau). \tag{110}
\]

The entropy per particle is also only a function of the temperature

\[
s = k \left[ \zeta_0 \frac{K_3(\zeta_0)}{K_2(\zeta_0)} - \frac{\mu_0}{kT_0} \right], \tag{111}
\]

thanks to (7) and (8). Following the same scheme we have used to obtain (108) we get the entropy per particle:

\[
\frac{s - s_0}{s_0} = - \left[ \frac{K_3(\zeta_0)}{K_2(\zeta_0)} \left( \zeta_0 \frac{K_3(\zeta_0)}{K_2(\zeta_0)} - 4 \right) - \zeta_0 \right] \Delta(\tau). \tag{112}
\]

Let us determine the equilibrium fields in the non-relativistic limiting cases where \( \zeta \gg 1 \). Under this condition the fields (9), (8) and (11) up to the order \( 1/\zeta \) read:

\[
e_0 = mc^2 + \frac{3}{2}kT_0 \left[ 1 + \frac{5}{4\zeta_0} \right], \tag{113}
\]

\[
s_0 = k \left[ \ln \frac{T_0^2}{n_0} + \frac{3}{2} \ln(2\pi\hbar km) + \frac{15}{4\zeta_0} \right], \tag{114}
\]

\[
\mu_0 = mc^2 + kT_0 \left[ \ln \frac{e\hbar n_0}{T_0^2} - \frac{3}{2} \ln(2\pi km) - \frac{15}{8\zeta_0} \right], \tag{115}
\]

\[
c_v^0 = \frac{3}{2} k \left[ 1 + \frac{5}{2\zeta_0} \right]. \tag{116}
\]

With (113) – (116) we obtain the behavior of the energy per particle (105), the pressure (110) and the entropy per particle (112):

\[
\frac{e - e_0}{kT_0} = \frac{3}{2} \left[ 1 + \frac{5}{2\zeta_0} \right] \Delta(\tau), \tag{117}
\]

\[
\frac{p - p_0}{p_0} = \left[ 1 + \frac{5}{2\zeta_0} \right] \zeta_0 \Delta(\tau), \tag{118}
\]

\[
\frac{s - s_0}{s_0} = \frac{1}{\ln \frac{e\hbar n_0}{T_0^2} - \frac{3}{2} \ln(2\pi km) - \frac{15}{8\zeta_0}} \Delta(\tau). \tag{119}
\]

Hence, apart from the factors, the energy per particle shows the same dependence on the gravitational field as the temperature and the chemical potential. However, the oscillation amplitudes of the pressure and the entropy per particle are larger, since they are multiplied by \( \zeta_0 = mc^2/kT_0 \) which has a big value in the non-relativistic limiting case.

C. Analysis of temperature oscillations

Now let us analyze the temperature oscillations of a gas, e.g., in a spacecraft, at low altitudes in orbits around the planets of the solar system, where we can approximate the orbit radius \( r \) by the radius of the massive object \( R \), i.e., \( r \approx R \). In the two first columns of Table I we specify the radii and the masses of the planets. The ratios \( M/R = GM/Rc^2 \) in the third column are sufficiently small so that we can use the approximation (71) for the oscillation \( \Delta(\tau) \). From the fourth column we infer that the frequencies \( \omega_N = \sqrt{GM/R^3} \) for the four outer planets are about one-half of the ones for the four inner planets. The fifth column contains the corresponding oscillation amplitudes \( GM/Rc^2 \).

In Figure 1 we show the temperature oscillations \( \Delta_N(\tau) \) of a gas in circular motion around the Earth, Mars and Saturn as function of the proper time \( \tau \). As an example we have considered that \( x_0 = x^2 = 1 \). The curves corroborate the data of the table, indicating that the frequencies for Earth and Mars are practically the
same but with different amplitudes, the amplitude of the latter being smaller than that of the former. For Saturn both the oscillation frequency and the amplitude are smaller than the corresponding quantities for the Earth and for Mars. Note that the fractional amplitudes of the oscillations are of the order of $10^{-23}$, i.e., they are very small.

As a second application we analyze the previously considered case $r = 7M$, which corresponds to strong fields. If the massive object has a radius of the order of the Earth’s radius, the Newtonian frequency is about $\omega_N \approx 17.77$ Hz. The temperature oscillations $\Delta(\tau)$ for this case are plotted in Fig. 2 as function of the proper time $\tau$. As to be expected, both the oscillation frequencies and the amplitudes here are larger than those for the planets of the solar system. Moreover, the frequency difference becomes clearly visible.

The oscillation amplitudes for the pressure and the entropy per particle are larger than those for the temperature, the energy per particle and the chemical potential, since the amplitudes of the former are multiplied by $\zeta_0 = mc^2/kT$. For a hydrogen gas $H_2$ at a temperature of 300 K this factor is about $\zeta_0 \approx 7.2 \times 10^{10}$. Hence the oscillations of the pressure and the entropy per particle are more remarkable than those for the temperature, the energy per particle and the chemical potential.

D. Compact objects

As already mentioned in the introduction, a potentially interesting application is the behavior of matter in the accretion disks of X-ray binaries. The observed quasi-periodic oscillations are supposed to represent effects of matter motion in strong gravitational fields [7-10]. While a Boltzmann gas at equilibrium does certainly not provide a realistic description of accretion disks, it might be useful nevertheless as an idealized toy model which perhaps captures at least some of the features of the real situation. In any case, the reason for the mentioned quasi-periodic oscillations appears to be unclear so far. The relevant frequencies are supposed to be related to test-particle frequencies. How this exactly occurs is an open problem. Very likely, hydrodynamic and/or plasma effects play a role here. Apparently, one has to find out how the individual particle motion is related to the dynamics of the medium in terms of fluid or plasma quantities. The point that our model makes is that it establishes a link between the motion of individual particles and thermodynamical quantities such as temperature and energy density. How idealized the model might
ever be, it translates particle oscillations into oscillations of fluid dynamical quantities. Such feature should be a necessary ingredient also in more realistic models.

Tentatively, we apply our model to strong-field configuration which are typically discussed in the literature (see, e.g., [8]). For a neutron star with mass $M = 1.4M_\odot$, where $M_\odot$ is the solar mass, the Schwarzschild radius is $r_S = \frac{2GM}{c^2} \approx 4.1\text{km}$. Let us consider a circular orbit at $r = 5r_S = 10M \approx 20.5\text{km}$. This corresponds to frequencies of about $\omega_N = 4.62 \cdot 10^3\text{Hz}$. Likewise let us consider a black hole of ten solar masses $M = 10M_\odot$. It has a Schwarzschild radius $r_S = \frac{2GM}{c^2} \approx 29.5\text{km}$. For circular orbits $r = 5r_S = 10M \approx 148\text{km}$ the frequencies are of the order of $\omega_N = 6.4 \cdot 10^2\text{Hz}$. As already mentioned, for any $r = 10M$ the frequency ratio $\Omega/\omega = \sqrt{2.5} \approx 1.58$ is of the order of the frequently observed ratio $3/2$ from X-ray binaries.

Figs. 3 and 4 visualize the temperature oscillations of a gas in circular motion around a neutron star with $r = 10M$ and $M = 1.4M_\odot$ and a black hole with $r = 10M$ and $M = 10M_\odot$, respectively. Because of the factor $\frac{M}{r^3}$ in the expression (20) for $\Delta(\tau)$ the amplitude of the oscillations is larger for the motion in the field of the neutron star.

X. SUMMARY

A Boltzmann gas at equilibrium may be seen as the simplest exactly calculable matter model that one

may think of. Although being an highly idealized configuration it sets a benchmark for more realistic models. We have shown here that the equilibrium condition, represented by Tolman’s law, dictates the entire thermo-hydrodynamics of the gas, including its behavior in strong gravitational fields. The temperature profile of the Boltzmann gas in circular geodesic motion in the Schwarzschild field turns out to be determined by oscillations with two frequencies, $2\omega = 2\sqrt{\frac{GM}{r^2}} \sqrt{\frac{r-S}{r-3M}}$ and $2\Omega = 2\sqrt{\frac{GM}{r^2}} \sqrt{\frac{r-S}{r-3M}}$, the difference of which is a purely general-relativistic effect. The oscillation frequencies of the temperature and of the other thermodynamic quantities like the energy per particle are exactly twice the frequencies for the test-particle motion. This feature is traced back to the parabolic temperature profile around the circular geodesics which, in turn, is a direct consequence of Tolman’s law, applied to (modified) Fermi normal coordinates which extend the concept of a proper reference frame to second-order deviations of the metric from the locally Minkowskian frame, carried by a comoving observer. Thus, the equilibrium condition allows us to relate properties of the individual particle motion to thermo-hydrodynamical variables. Different from the test-particle oscillation frequencies (29) and (30) in Schwarzschild coordinates, reviewed in Sec. V, a comoving observer does not measure a precession within the orbital plane since oscillations occur with the same frequency $2\omega$ both in radial and in tangential directions. But the oscillation frequency $2\Omega$ perpendicular to the orbital plane does not coincide with the frequency in the plane. The frequency difference is almost negligible in the vicinity of the planets of the solar system. It may crucially affect, however, the matter dynamics close to
compact astrophysical objects like neutron stars or black holes.
