Abstract

A new, simple and sensitive adsorptive stripping voltammetric procedure for determination of paracetamol at a lead film glassy carbon electrode modified with Nafion film (Nafion/PbF/GCE) in pharmaceutical formulations was described. Deposition of lead film on a glassy carbon electrode from 0.1 mol L\textsuperscript{-1} HNO\textsubscript{3} at the potential of -1.4 V was performed. The Nafion film coating was carried out by applying a 0.5 µL drop of 1% (w/v) Nafion solution onto the lead film electrode surface. At the potential of -1.45 V for 60 s paracetamol was accumulated by adsorption on the electrode from 0.1 mol L\textsuperscript{-1} H\textsubscript{2}SO\textsubscript{4}. Experimental results indicate excellent linear correlation between the paracetamol peak current and its concentration in the range from 5 × 10\textsuperscript{-7} to 1 × 10\textsuperscript{-2} mol L\textsuperscript{-1} with accumulation time equal to 60 s. The detection and quantification limits were 1.72 × 10\textsuperscript{-7} mol L\textsuperscript{-1} and 5.97 × 10\textsuperscript{-7} mol L\textsuperscript{-1}, respectively. The elaborated procedure was successfully applied for determination of paracetamol in commercially available pharmaceutical formulations.

Keywords: Nafion covered lead film glassy carbon electrode; Adsorptive stripping determination; Paracetamol determination; Pharmaceutical analysis

Introduction

Paracetamol (acetaminophen, N-acetyl-p-aminophenol, PA) is a widely used pain reliever and fever reducer. At normal therapeutic doses, PA is metabolized very fast and fully eliminated in urine [1]. However, overdose of PA can lead to accumulation of toxic metabolites which may cause hepatotoxicity and nephrotoxicity [2]. Because of its broad therapeutic use, it is necessary to develop fast, simple and accurate methodologies for determination of paracetamol for medical control in biological fluids and quality control analysis in pharmaceutical formulations. Therefore, many methods have been developed to determine acetaminophen including titrimetry [3,4], UV/VIS spectrophotometry [5-7], spectrofluorometry [8-11], chromatography [12-15]. However, these methods are burdened with some disadvantages such as high cost, long analysis time and the need for sample preparation. Electrochemical method has attracted much attention because of quick response, high sensitivity, as well as low-cost analysis. Since paracetamol is an electroactive compound, electrochemical sensors represent an interesting alternative for its quantification. Most electrochemical methods are based on the use of modified carbon - based electrodes such as modified carbon-ceramic electrode with single-walled carbon nanotubes (SWCNT/CCE) [16,17], modified edge plane pyrolytic graphite electrode with single-walled carbon nanotubes (SWCNT/EPPGE) [18], basal plane pyrolytic graphite electrode modified by multi-walled carbon nanotubes (MWCNT-BPPGE) [19], polyaniline-multi-walled carbon nanotubes composite modified electrode (PANI-MWCNT) [20], luteolin/functionalyzed multi-walled carbon nanotubes modified glassy carbon electrode (LtfMWCNT/MGCE) [21], gold nanoparticles multi-walled carbon nanotube modified glassy carbon electrode (AuNPs/MWCNT/GCE) [22], 8,9-dihydroxy-7-methyl-12H-benzothiazolo[2,3b]quinazolin-12-one modified multi-walled carbon nanotubes paste electrode (DMBQ-MWCNTPE)
of Pb(NO₃)₂ was prepared from reagent obtained from Sigma. Recently, the boron-doped diamond electrode modified with Nafion and lead films (PbF/Nafion/BDDE) was applied for simultaneous voltammetric determination of paracetamol and ascorbic acid [32]. It should be also noted, that a glassy carbon electrode modified first by lead film and then by Nafion film (Nafion/PbF/GCE) was used for determination of caffeine in beverage samples and pharmaceutical formulations [33].

The measurements were carried out using a classical three-electrode quartz cell of 10 mL volume. A modified glassy carbon electrode with the diameter of 1 mm was used as the working electrode. The GC electrode was polished daily using 0.3 µm alumina slurry on a Buehler polishing pad. A platinum wire and Ag/AgCl (3 mol L⁻¹ KCl) were used as auxiliary and reference electrodes, respectively. The pH measurements were made using an Elmetron pH meter Cl-316.

Preparation of Nafion/PbF/GCE

The Nafion covered lead film electrode was prepared in two steps. In the first one, the lead film was plated onto a glassy carbon support from 0.1 mol L⁻¹ solution of HNO₃ containing 7.5 × 10⁻⁵ mol L⁻¹ Pb(NO₃)₂. The potential of the electrode was changed in the following sequence: 0.5 V for 30 s and -1.4 V for 30 s. The first potential was applied to clean the electrode surface before deposition of lead film. At the potential of -1.4 V lead ions were reduced to the metallic state onto a glassy carbon support. During these steps the solution was stirred using a magnetic stirring bar. After the deposition of the lead film, the electrode was rinsed with deionized water and was left to dry in air for 2 min. In the second step, the Nafion film coating was obtained by applying 0.5 µL of the Nafion solution (1% w/v) onto the lead film electrode surface and allowing the system to dry in air for 2 min in a room temperature.

Procedure of paracetamol determinations at Nafion/PbF/GCE

All voltammetric measurements at the Nafion covered lead film electrode were carried out in 0.1 mol L⁻¹ H₂SO₄ containing variable concentration of paracetamol. At the potential of -1.45 V for 60 s paracetamol was accumulated by adsorption from stirred solution on the electrode. Then after a rest period of 5 s the anodic square wave voltammograms were registered in the range from -1.45 to 1.0 V, with frequency of 200 Hz, amplitude of 50 mV and step height 2 mV. During the stripping step paracetamol was removed from the modified glassy carbon electrode surface. The measurements were carried out in non-deaerated solutions.

Sample preparation

The determinations of PA performer in commercially available formulations: tablets no. 1 containing 750 mg PA per tablet, tablets no. 2 and 3 containing 500 mg PA per tablet. The pharmaceuticals were prepared by the following procedure. Ten tablets were carefully ground to a fine powder, and then the quantity of homogenous powder equivalent to the average weight per tablet was dissolved in an appropriate amount of deionized water. Tablets no. 1 were dissolved in 250 mL of water supplied by a Milli-Q system. Other pharmaceuticals were dissolved in 25 mL of deionized water by sonication for 15 min and then were filtered using a Millipore filter with average the pore diameter of 0.45 µm. A suitable amount of so prepared samples was added to the supporting electrolyte in the voltammetric cell and analysed directly by adsorptive stripping voltammetry.
Results and Discussion

Voltammetric behaviour of PA at Nafion/PbF/GCE

The oxidation mechanism of paracetamol has been investigated in the literature. Oxidation of PA involves a two-electron and two-proton transfer process to form an unstable oxidized product N-acetyl-p-quinoneimine (NAPQI) (Figure 1) [29,31,34].

Preliminary electrochemical measurements were carried out in order to evaluate the advantages of the Nafion covered lead film electrode with respect to bare and Nafion covered glassy carbon electrode, ex situ and in situ plated lead film electrode as well as ex situ plated lead film electrode modified with Nafion. Figure 2 shows voltammograms obtained during the determination of paracetamol at these electrodes. In all cases, measurements of paracetamol were carried out in the solution containing 0.1 mol L\(^{-1}\) H\(_2\)SO\(_4\) and 5 \times 10\(^{-5}\) mol L\(^{-1}\) paracetamol at the potential of -1.55 V for 120 s. The lead film was plated ex situ from the solution containing 0.1 mol L\(^{-1}\) HNO\(_3\) and 7.5 \times 10\(^{-5}\) mol L\(^{-1}\) Pb(NO\(_3\))\(_2\) at the potential of -1.4 V for 30 s. The Nafion film coating was obtained by applying 0.5 µL of the Nafion solution (1% w/v) onto the electrode surface. As it can be seen in Figure 2, the ex situ plated lead film electrode covered with Nafion offers the highest signal of PA and the lowest background, as compared to other electrodes. According to the literature data modification of the surface of the glassy carbon electrode with lead film increases active surface area causing better accumulation of the analyte [35,36]. Furthermore, the advantages of using the Nafion film are related to preconcentration of the analyte in the polymer layer which has already been emphasized by other authors [37,38]. Therefore, the Nafion covered lead film electrode was confirmed as the best choice for further studies.

Optimization of the electrode modification

In respect to the electrode modification by Nafion and lead films the key parameters, such as the concentration of Pb(II) and Nafion, the volume of Nafion solution applied onto the electrode surface were optimized. The Pb(II) concentration in the lead film plating solution was changed in the range from 0 to 2.5 \times 10\(^{-4}\) mol L\(^{-1}\). It was observed that the oxidation peak current of 5 \times 10\(^{-5}\) mol L\(^{-1}\) PA attained maximum value when the concentration of Pb(II) was 7.5 \times 10\(^{-5}\) mol L\(^{-1}\) (Figure 3A). Next, the effect of the Nafion concentration on the voltammetric response of PA was investigated. The Nafion film coating was carried out by applying a 0.5 µL drop of solution containing Nafion concentration in the range from 0.5 to 2.5% (w/v). The obtained results were shown in Figure 3B. It can be seen that the peak current of PA reached a maximum at 1% w/v Nafion concentration. The results indicate that the Nafion films produced by 0 or 0.5% and higher than 1% w/v Nafion solution were too thin or thick for PA determination. If the Nafion layer is too thin, some parts of the electrode may not be covered and the efficiency may decrease. On the other hand, too thick Nafion film displayed large cracks due to contractive forces within the layer hindering effective mass transport [39]. Then, the volume of Nafion drop applied onto the electrode surface was changed in the range from 0 to 1 µL and influence on the peak current of 5 \times 10\(^{-8}\) mol L\(^{-1}\) PA was studied. It was observed that the paracetamol peak attained maximum value for the volume of Nafion drop equal to 0.5 µL. For further experiments a 0.5 µL drop of Nafion solution at concentration of 1% w/v was used for the preparation of the Nafion/PbF/GCE.
Optimization of the paracetamol determination procedure

The influence of accumulation potential on the paracetamol peak current was studied for PA concentration of $5 \times 10^{-5}$ mol L$^{-1}$. The potential was changed in the range from -1.4 to -1.6 V. As can be seen in Figure 4A, the oxidation peak of PA attained maximum value at the accumulation potential of -1.45 V, so for further measurements this potential was chosen. The effect of accumulation time was studied for paracetamol concentration of $5 \times 10^{-5}$ mol L$^{-1}$. The accumulation time was changed from 0 to 300 s. It was

Figure 3 Impact of: (A) Pb(II) and (B) Nafion concentration on the peak current of $5 \times 10^{-5}$ mol L$^{-1}$ PA. Other measurements parameters are the same as in Figure 2

Figure 4 Effect of accumulation potential (A) and time (B) on the peak current of $5 \times 10^{-5}$ mol L$^{-1}$ PA. The lead film was deposited at -1.4 V for 30 s from solution containing $7.5 \times 10^{-5}$ mol L$^{-1}$ Pb(NO$_3$)$_2$. The Nafion film coating was carried out by applying a 0.5 µL drop of 1% (w/v) Nafion solution. In the case of (A) the accumulation time of PA was 120 s. Other measurements parameters are the same as in Figure 2
observed that paracetamol response signals increased upon increasing the accumulation time to 60 s and then started to decrease at longer times (Figure 4B). On the basis of these results the accumulation time of 60 s was chosen for further studies.

Calibration graph, repeatability and reproducibility

Under the optimal analytical conditions, determination of paracetamol with increasing concentration was performed. The calibration graph for the accumulation time of 60 s was linear from $5 \times 10^{-7}$ to $1 \times 10^{-2}$ mol L$^{-1}$, and was compliant with the equation $y = 12.56x + 0.297$, where $y$ is the peak current (µA) and $x$ is a paracetamol concentration (mmol L$^{-1}$). The correlation coefficient ($R^2$) was 0.9997. The limits of detection and quantification estimated from 3-times and 5-times the standard deviation ($n=5$) for the lowest determined concentration of paracetamol were $1.72 \times 10^{-7}$ mol L$^{-1}$ and $5.97 \times 10^{-7}$ mol L$^{-1}$, respectively.

The repeatability of the signal was determined by successive measurements ($n=5$) of each studied paracetamol concentration at the same electrode. The relative standard deviation of the peak current in the range from 3.8% to 4.2% was obtained. Moreover, the electrode-to-electrode reproducibility was estimated with five replicate determinations of paracetamol concentration from 3-times and 5-times the standard deviation ($n=5$) for the lowest determined concentration of paracetamol were $1.72 \times 10^{-7}$ mol L$^{-1}$ and $5.97 \times 10^{-7}$ mol L$^{-1}$, respectively.

Interferences

To investigate the interference effects of some compounds, a fixed amount of $1 \times 10^{-5}$ mol L$^{-1}$ paracetamol spiked with various foreign species, such as glucose, fructose, saccharin, sodium carbonate, citric acid, ascorbic acid and acetylsalicylic acid was evaluated under the same experimental conditions. The results showed that at a 10-fold excess these species had no impact on the peaks current of paracetamol (signals changed below 5%).

Real sample analysis

The optimized voltammetric procedure was used with the standard addition method to the determination of paracetamol in commercially available pharmaceutical formulations. The obtained results are shown in Table 2.
As can be seen in this table, no significant differences were observed between the label (data supplied by the manufacturer) and found (data obtained by the proposed voltammetric procedure) values of paracetamol in samples. On the basis of obtained results, it can be stated that the proposed method was found suitable for determination of PA in its pharmaceutical formulations without any interference from sample matrices. The voltammograms obtained in the course of PA determination in pharmaceutical formulation no. 2 at the Nafion covered lead film glassy carbon electrode are presented in Figure 5.

**Conclusions**

The approach adopted in this work provides a new voltammetric procedure for determination of paracetamol using a Nafion covered lead film glassy carbon electrode in pharmaceutical formulation. The proposed procedure is characterized by major advantages, such as short determination time, low cost, very wide linear range of paracetamol concentrations, low detection and quantification limits and no impact of the pharmaceutical sample matrix on PA signals. Thanks to these properties, the developed procedure using the Nafion/PbF/GCE provides a useful tool for the detection and quantification of paracetamol in commercial formulation.

**Table 2:** The results of PA determination in pharmaceutical formulations (no. 1, 2, 3) obtained by the proposed voltammetric procedure. The relative standard deviations (RSD) are given in % for n=5. The relative error (%)=100 × (found value-label value)/label value.

| Pharmaceutical formulation | Label value (mg/tablet) | Found value ± RSD (mg/tablet) ± (%) | Relative error (%) |
|-----------------------------|-------------------------|-------------------------------------|--------------------|
| 1                           | 750                     | 740.9 ± 3.3                         | -1.2               |
| 2                           | 500                     | 493.5 ± 3.0                         | -1.3               |
| 3                           | 500                     | 502.0 ± 3.3                         | 0.4                |
