NEAR ORDERS AND CODES

C. CARVALHO, C. MUNUERA, E. SILVA, AND F. TORRES

Abstract. Høholdt, van Lint and Pellikaan used order functions to construct codes by means of Linear Algebra and Semigroup Theory only. However, Geometric Goppa codes that can be represented by this method are mainly those based on just one point. In this paper we introduce the concept of near order function with the aim of generalize this approach in such a way that a of wider family of Geometric Goppa codes can be studied on a more elementary setting.

1. Introduction

Geometric Goppa codes (or GG codes, for short) were constructed by Goppa [6], [7] based on a curve $X$ over a finite field $\mathbb{F}$, and two $\mathbb{F}$-rational divisors $D$ and $G$ on $X$. Here, by a curve we mean a projective, geometrically irreducible, non-singular algebraic curve. Usually the divisors $D$ and $G$ are chosen as

- $D = P_1 + \ldots + P_n$;
- $G = \alpha_1 Q_1 + \ldots + \alpha_\ell Q_\ell$,

where the $P_i$’s and $Q_j$’s are pairwise different $\mathbb{F}$-rational points of $X$. Then, there are two GG codes associated to the triple $(X, D, G)$, defined as the images $C_L = C_L(X, D, G)$ and $C_\Omega = C_\Omega(X, D, G)$ of the maps

$ev : f \in \mathcal{L}(G) \mapsto (f(P_1), \ldots, f(P_n)) \in \mathbb{F}^n$ and

$res : \omega \in \Omega(G - D) \mapsto (\text{res}_{P_1}(\omega), \ldots, \text{res}_{P_n}(\omega)) \in \mathbb{F}^n$

respectively. According to the residue theorem, these codes are dual to the other, $C_L = C_\Omega^\perp$, hence both constructions provide the same family of codes. Bounds on the dimension

\textbf{Keywords and Phrases:} Error-correcting codes, algebraic geometric Goppa codes, Weierstrass semigroups, order function.

\textbf{2000 Math. Subj. Class.:} 94B27; 14G50.

The work of C. Carvalho was partially supported by FAPEMIG, grant CEX 605/05; research done under a joint project of the Millennium Institute for the Global Advancement of Brazilian Mathematics (IM-AGIMB) and Universidade Federal de Uberlândia (UFU).

The work of C. Munuera was supported by the "Junta de Castilla y León", España, under Grant VA020-02.

The work of E. Silva was partially supported by FAPEMIG; this paper is based on his Ph.D dissertation [21] done at IMECC-UNICAMP, SP-Brazil.

The work of F. Torres was supported by CNPq-Brazil (306676/03-6) and PRONEX (66.2408/96-9).
and minimum distance of such codes are available from their definition, as they satisfy
\( k = \ell(G) - \ell(G - D), \quad d \geq n - \deg(G) \) for \( C_L \) and \( k = i(G - D) - i(G), \quad d \geq \deg(G) - 2\gamma + 2 \) for \( C_\Omega \) (where \( \gamma \) is the genus of \( X \)). Soon after its introduction, GG codes became a
very important tool in Coding Theory; for example, Tsfasman, Vladut and Zink [22]
showed that the Varshamov-Gilbert bound can be attained by using these codes. The
way of dealing with the dimension and minimum distance of \( C \) is via the Riemann-Roch
theorem; in particular one needs to compute the genus of the underlying curve which may
be a difficult task. Thus it will be of interest to construct and manage GG codes by using
“elementary methods” only. An important step in this direction was given by Høholdt,
von Lint and Pellikaan [8] (see also [2]), who used order functions (see Section 2.2) to
construct codes from an \( F \)-algebra \( R \). Order functions and the obtained codes have been
studied in detail by Pellikaan, Geil and other authors (see [3], [20]). This technique allows
us to do mainly with “one-point GG” codes –that is to say, when \( \ell = 1 \) in the definition
of divisor \( G \) above–. The objective of this paper is to introduce and study a wider class of
“order-like” functions (the called near order functions; see Section 3) in such a way that
more GG codes could be represented by those elementary methods.

2. Background

2.1. Weierstrass Semigroups and Geometric Goppa Codes. Let \( X \) be a curve over a finite
field \( \mathbb{F} \). For a point \( P \in X \), let \( \mathcal{O}_P \) and \( v_P \) denote the local ring and valuation of \( X \) at \( P \) respectively. Following [8], we consider the \( F \)-algebra
\[ R = R(Q_1, \ldots, Q_\ell) := \bigcap_{R \neq Q_1, \ldots, Q_\ell} \mathcal{O}_R, \]
where the \( Q_i \)'s are as in Section 1. We shall consider also the Weierstrass semigroup of \( X \)
at \( Q_1, \ldots, Q_\ell \), namely
\[ H = H(Q_1, \ldots, Q_\ell) \]
\[ = \{ (\beta_1, \ldots, \beta_\ell) \in \mathbb{N}_0^\ell : \text{there exists } f \in R \text{ with } \text{div}_\infty(f) = \beta_1 Q_1 + \ldots + \beta_\ell Q_\ell \}. \]
These semigroups have been intensively studied in connection with Coding Theory; see
for example [1], [3], [4], [9], [10], [11], [12], [13], [14], [16], [17], [18], [19]. The relationship
between \( R \) and \( H \) above suggests that Goppa codes can be represented by elementary
means. As was already mentioned, this was noticed in [8] for the case \( \ell = 1 \) (see also [15]).

2.2. Order Functions. Our reference in this section is the paper [8]. Let \( R \) be an \( F \)-
algebra. A function \( \rho : R \to \mathbb{N}_0 \cup \{-\infty\} \) is called an order function if the following properties
\[ (O0) \, \rho(f) = -\infty \text{ if and only if } f = 0; \]
\[ (O1) \, \rho(\lambda f) = \rho(f) \text{ for all } \lambda \in \mathbb{F}^*; \]
NEAR ORDERS AND CODES

(O2) \( \rho(f + g) \leq \max\{\rho(f), \rho(g)\} \);

(O3) If \( \rho(f) < \rho(g) \) and \( h \neq 0 \), then \( \rho(fh) < \rho(gh) \); and

(O4) If \( \rho(f) = \rho(g) \neq -\infty \), then there exists \( \lambda \in \mathbb{F}^* \) such that \( \rho(f - \lambda g) < \rho(g) \),

are satisfied for all \( f, g, h \in \mathbb{R} \). If in addition

(O5) \( \rho(fg) = \rho(f) + \rho(g) \),

then \( \rho \) is called a weight function. We collect some properties of order functions.

**Lemma 2.1.** ([8, Lemma 3.9]) With notation as above:

1. If \( \rho(f) = \rho(g) \), then \( \rho(fh) = \rho(gh) \) for all \( h \in \mathbb{R} \);
2. If \( f \in \mathbb{R} \setminus \{0\} \), then \( \rho(1) \leq \rho(f) \);
3. \( \mathbb{F}^* = \{ f \in \mathbb{R} : \rho(f) = \rho(1) \} \);
4. If \( f \neq 0, g \neq 0 \) and \( \rho(f) = \rho(g) \), then there exists a unique nonzero \( \lambda \in \mathbb{F} \) such that \( \rho(f - \lambda g) < \rho(f) \);
5. If \( \rho(f) \neq \rho(g) \), then \( \rho(f + g) = \max\{\rho(f), \rho(g)\} \).

**Remark 2.2.** According to the lemma above, the \( \mathbb{F} \)-algebra \( \mathbb{R} \) splits as \( \mathbb{R} = \mathcal{M} \cup \mathcal{U} \), where

\[ \mathcal{M} = \{ f \in \mathbb{R} : \rho(f) > \rho(1) \}, \quad \text{and} \quad \mathcal{U} = \{ f \in \mathbb{R} : \rho(f) \leq \rho(1) \} . \]

As a matter of fact, \( \mathcal{U}^* := \mathcal{U} \setminus \{0\} = \{ f \in \mathbb{R} \setminus \{0\} : \rho(f) = \rho(1) \} = \mathbb{F}^* \).

3. Near Order Functions

In this section we study a “weak” version of the concept of order and weight function discussed in Section 2. The starting point for our discussion is Remark 2.2.

3.1. Near Order Functions. Let \( \mathbb{R} \) be an \( \mathbb{F} \)-algebra and let \( \rho : \mathbb{R} \to \mathbb{N}_0 \cup \{-\infty\} \) be a function with \( \rho(0) = -\infty \). Associated to \( \rho \) we can consider the sets:

\[ \mathcal{U} = \mathcal{U}_\rho := \{ f \in \mathbb{R} : \rho(f) \leq \rho(1) \} , \]

\[ \mathcal{U}^* = \mathcal{U}^*_\rho := \mathcal{U} \setminus \{0\} , \]

\[ \mathcal{M} = \mathcal{M}_\rho := \{ f \in \mathbb{R} : \rho(f) > \rho(1) \} . \]

In addition, let \( \mathcal{U} = \mathcal{U}_\rho := \mathcal{U}^* \cup \{0\} \). We say that \( \rho \) is a near order function (or n-order function, for short) if properties

(N0) \( \rho(f) = -\infty \) if and only if \( f = 0 \); 
(N1) \( \rho(\lambda f) = \rho(f) \) for all \( \lambda \in \mathbb{F}^* \); 
(N2) \( \rho(f + g) \leq \max\{\rho(f), \rho(g)\} \);

similar to the corresponding concerning order functions hold true, and for \( f, g, h \in \mathbb{R} \) we have:
(N3) If \( \rho(f) < \rho(g) \) then \( \rho(fh) \leq \rho(gh) \). Furthermore, if \( h \in M \), then \( \rho(fh) < \rho(gh) \);
(N4) If \( \rho(f) = \rho(g) \) with \( f, g \in M \), then there exists \( \lambda \in \mathbb{F}^* \) such that \( \rho(f - \lambda g) < \rho(f) \).

Clearly an order function is also a n-order (cf. Remark 2.2). We can also construct n-orders functions on \( R \) which are not orders functions.

**Example 3.1.** (a) Let \( \rho(0) = -\infty \) and for \( f \in R \setminus \{0\} \) put \( \rho(f) := c \in \mathbb{N}_0 \) (constant). Here \( M = \emptyset \) and \( U = R \), so \( \rho \) is trivially a n-order on \( R \) which is not an order (it is an order function if and only if \( R = \mathbb{F} \)).

(b) Fix \( g \in R \setminus F \) and define \( \rho(f) = -\infty \) if and only if \( f = 0 \); \( \rho(f) := 0 \) if \( f \in \langle g \rangle \), \( f \neq 0 \); \( \rho(f) = 1 \) otherwise. Then \( \rho \) is a n-order function with \( \rho(1) = 1 \) and \( U = R \).

The examples above shows the existence of n-order functions on an arbitrary \( \mathbb{F} \)-algebra. Note that in both cases it holds that \( U = R \) hence \( M = \emptyset \). N-orders verifying this condition will be called trivial. For non-trivial n-orders both sets \( M \) and \( \rho(M) \) have infinitely many elements. This is a consequence of (N3), since \( \rho(1) < \rho(f) \) implies \( \rho(f^i) < \rho(f^{i+1}) \). An example of a nontrivial n-order is the following.

**Example 3.2.** Let \( R = \mathbb{F}[X, Y]/(XY - 1) = \mathbb{F}[x, y] \) with \( x, y \) being the class of \( X \) and \( Y \) respectively. Every \( f \in R \) admits a unique decomposition of type \( f = f_1(x) + f_2(y) \), where \( f_1, f_2 \in \mathbb{F}[T] \) with \( f_2(0) = 0 \). It is known that \( R \) does not admit any order function, [8, Ex. 3.11]. However, \( R \) admits a non-trivial n-order function, namely

\[
\rho(f) := \begin{cases} 
-\infty & \text{if } f = 0, \\
0 & \text{if } f_1 \neq 0 \text{ and } f_2 = 0, \\
\deg(f_2) & \text{if } f_2 \neq 0.
\end{cases}
\]

Here \( \rho(1) = 0 \), \( M = \{ f_1(x) + f_2(y) : f_2 \in \mathbb{F}[t], f_2 \neq 0 \text{ and } f_2(0) = 0 \} \), \( U = \{ f_1(x) : f_1 \in \mathbb{F}[t] \} \); an straightforward computation shows that \( \rho \) is in fact a n-order function.

The relation between orders and n-orders is clarified by the following result, which complements Remark 2.2.

**Lemma 3.3.** Let \( \rho : R \to \mathbb{N}_0 \cup \{-\infty\} \) be a function defined on a \( \mathbb{F} \)-algebra \( R \). Let \( U = U_\rho \) be the set of elements \( f \in R \) with \( \rho(f) \leq \rho(1) \). Then the following statements are equivalent:

1. \( \rho \) is an order;
2. \( \rho \) is a n-order and \( U = \mathbb{F} \).

Note that, as a consequence of property (N1), for any n-order on \( R \) it holds that \( \mathbb{F} \subseteq U \). The above lemma shows that equality holds just for orders. On the other hand, it was noticed in [8, Prop. 3.10] that any \( \mathbb{F} \)-algebra equipped with an order function is an integral domain but the inverse statement is false; cf. Example 3.2. We stress the fact that any \( \mathbb{F} \) algebra can be equipped with a n-order function; cf. Examples 3.1 3.2.
Lemma 3.4. Let \( R \) be an \( \mathbb{F} \)-algebra and \( \rho \) a \( n \)-order on \( R \). Then the set \( M_{\rho} \) does not contain zero divisors.

Proof. Let \( g \in R \setminus \{0\} \) and \( f \in M \). Since \( \rho(1) < \rho(f) \) it holds that \( \rho(g) \leq \rho(fg) \) by Axiom (\( N3 \)). Hence \( fg \neq 0 \). \( \square \)

Let us see one more example. As said in the Introduction, our purpose is to manage Goppa codes over more than one point by means of “order-like” functions. This example shows a way to obtain \( n \)-order functions from points on curves (cf. Section 5).

Example 3.5. Let \( X \) be a curve over a finite field \( \mathbb{F} \). Let \( Q_1, \ldots, Q_\ell \) be pairwise different \( \mathbb{F} \)-rational points of \( X \) and \( R = R(Q_1, \ldots, Q_\ell) \) the algebra defined in Section 2.1. For each point \( Q_i \), define the function \( \rho_i = \rho_{Q_i} : R \to \mathbb{N}_0 \cup \{-\infty\} \) by \( \rho_i(f) = -\infty \) if and only if \( f = 0 \), and

\[
\rho_i(f) = \begin{cases} 
0 & \text{if } v_{Q_i}(f) \geq 0, \\
-v_{Q_i}(f) & \text{if } v_{Q_i}(f) < 0.
\end{cases}
\]

Then \( \rho_i(1) = 0 \) and hence \( U_i^* = \{ f \in R^* : v_{Q_i}(f) \geq 0 \} \). As a consequence of properties regarding valuation maps, \( \rho_i \) is indeed a \( n \)-order function (and in fact a \( n \)-weight as we shall define it later).

Note that in the one-point case (\( \ell = 1 \)) it holds that

\[
H(Q_1) = \{-v_{Q_1}(f) : f \in R^*\}.
\]

In the multiple-point case (\( \ell > 1 \)) we must use the functions \( \rho_i \)'s instead of the valuations \( -v_{Q_i} \)'s in order to describe the Weierstrass semigroup; indeed,

\[
H(Q_1, \ldots, Q_\ell) = \{(\rho_1(f), \ldots, \rho_\ell(f)) : f \in R^*\}.
\]

This fact gives a motivation to define the concept of near order.

Now we subsume further properties of \( n \)-order functions that are similar to those of order functions (cf. \( \S \) Lemma 3.9)).

Lemma 3.6. Let \( \rho \) be a \( n \)-order function on a \( \mathbb{F} \)-algebra \( R \). The following statements hold:

1. If \( f, g, h \in M_{\rho} \) and \( \rho(f) = \rho(g) \), then \( \rho(fh) = \rho(gh) \);
2. The element \( \lambda \) in Axiom (\( N4 \)) is unique;
3. If \( \rho(f) \neq \rho(g) \), then \( \rho(f + g) = \max\{\rho(f), \rho(g)\} \).

Proof. Similar to the proof of \( \S \) Lemma 3.9(1),(2),(4)]. \( \square \)
3.2. Normalized Near Orders and Near Weights Functions. Let \( \rho \) be a n-order function on \( \mathbb{R} \). As we shall see in the forthcoming sections, we will be interested in the value of \( \rho(f) \) when \( f \in \mathcal{M} \) but not when \( f \in \mathcal{U} \). Thus we can consider the normalization of \( \rho \) as the function \( \tilde{\rho} \) defined as

\[
\tilde{\rho}(0) = -\infty \quad \text{and for } f \neq 0 \quad \tilde{\rho}(f) = \begin{cases} 
0 & \text{if } f \in \mathcal{U}_\rho; \\
\rho(f)/d & \text{if } f \in \mathcal{M}_\rho,
\end{cases}
\]

where \( d = \gcd(\rho(\mathcal{M})) \). It is clear that \( \tilde{\rho} \) is also a n-order function, \( \mathcal{M}_{\tilde{\rho}} = \mathcal{M}_\rho \) and \( \mathcal{U}_{\tilde{\rho}} = \mathcal{U}_\rho \). The n-order function \( \rho \) is said to be normal if \( \rho = \tilde{\rho} \). In what follows, all the n-orders functions we consider will be understood as normal.

A (normal) n-order function \( \rho \) is called a near weight (or n-weight, for short) if it verifies the supplementary condition

\[(N5) \quad \rho(fg) \leq \rho(f) + \rho(g). \quad \text{If } f, g \in \mathcal{M}, \text{ then equality holds.}\]

Two interesting properties of n-weights arise at once from its definition

**Proposition 3.7.** Let \( \rho \) be a n-weight function on the \( \mathbb{F} \)-algebra \( \mathbb{R} \). Then

1. the set \( \rho(\mathbb{R} \setminus \{0\}) \) is a numerical semigroup of finite genus;
2. the set \( \mathcal{U}_\rho \) is closed under product and so it is a subalgebra of \( \mathbb{R} \).

Next, motivated by Proposition 3.12 and Theorem 3.14 in \[8\], we point out a relation between n-order functions \( \rho \) on \( \mathbb{R} \) and subspaces of \( \mathbb{R} \). Set \( \rho(\mathbb{R} \setminus \{0\}) = \{0 = \rho_0 < \rho_1 < \rho_2 < \ldots \} \) and

- For \( i \in \mathbb{N}_0 \), \( L_i := \{f \in \mathbb{R} : \rho(f) \leq \rho_i\} \); 
- For \( f \neq 0 \) define \( \iota(f) \) as the least non-negative integer \( \ell \) such that \( f \in L_\ell \); 
- For \( i, j \in \mathbb{N}_0 \), \( \ell(i,j) := \max\{\iota(fg) : f \in L_i \text{ and } g \in L_j\} \).

**Proposition 3.8.** Let \( \rho \) be a n-order function on a \( \mathbb{F} \)-algebra \( \mathbb{R} \) whose set of non-units is not empty. Then the following statements hold true:

1. \( (L_i) \) is an increasing sequence of vector subspaces of \( \mathbb{R} \) such that:
   a. \( \mathbb{F} \subseteq L_0 \);
   b. \( \dim(L_{i+1}) = \dim(L_i) + 1 \);
   c. \( \cup_i L_i = \mathbb{R} \);
2. \( \ell(i,j) = \ell(j,i) \), and for all \( i \in \mathbb{N}_0 \):
   a. If \( j \geq 1 \), then \( \ell(i,j) < \ell(i+1,j) \);
   b. If \( j = 0 \), then \( \ell(i,0) \leq \ell(i+1,0) \);
3. If \( \rho \) is a n-weight function, then \( \rho_{\ell(i,j)} \leq \rho_i + \rho_j \) for \( i, j \in \mathbb{N}_0 \). If \( i, j \geq 1 \) the equality holds.

**Proof.** (1) The fact that the \( L_i \)'s are vector spaces follows from properties \( (N0),(N1) \) and \( (N2) \) of n-order functions. (1.a) was already noted. (1.b) holds as a consequence
of properties (N2) and (N4). Statement (1.e) is obvious; (2) is a direct consequence of property (N3); (3) follows from (N5).

Remark 3.9. As doing in [8], the above proposition can be partially written in terms of functions instead of subspaces. Indeed, for \( i \in \mathbb{N} \), let \( f_i \in L_i \setminus L_{i-1} \). Then

1. \( \iota(f_i) = i \) and \( \rho(f_i) = \rho_i; \)
2. The set \( (f_i) \) is linearly independent and \( R = U \oplus \langle f_1, f_2 \ldots \rangle. \)
3. For \( i, j \in \mathbb{N} \), \( \ell(i, j) = \iota(f_ifj). \)

Conversely, we will prove that certain sequences of subspaces of \( R \) defines a \( n \)-order function on \( R \). Let \( L_0 \subseteq L_1 \subseteq \ldots \) be an increasing sequence of vector subspaces of \( R \) verifying the conditions:

1a. \( F \subseteq L_0; \)
1b. \( \dim(L_{i+1}) = \dim(L_i) + 1; \)
1c. \( \cup_i L_i = R. \)

Let \( 0 = \rho_0 < \rho_1 < \ldots \) be a sequence of positive integers whose cardinality is the same as the sequence \( (L_i) \) and such that \( \gcd(\rho_i) = 1 \). For \( f \neq 0 \) define \( \iota(f) \) as being the least non-negative integer \( \ell \) such that \( f \in L_\ell \). For \( i, j \in \mathbb{N}_0 \), set

\[ \ell(i, j) := \max\{\iota(fg) : f \in L_i \text{ and } g \in L_j\}. \]

The following proposition arises:

**Proposition 3.10.** Notation as above. Let \( \rho : R \to \mathbb{N}_0 \cup \{ -\infty \} \) be the function defined by \( \rho(0) = -\infty \) and \( \rho(f) = \rho_\ell(f) \) for \( f \neq 0 \). If the following two conditions:

2a. If \( j \geq 1 \), then \( \ell(i, j) < \ell(i + 1, j) \),
2b. If \( j = 0 \), then \( \ell(i, 0) \leq \ell(i + 1, 0) \)

hold, then \( \rho \) is a \( n \)-order function; if, in addition, \( \rho_\ell(i, j) \leq \rho_i + \rho_j \) with equality if \( i, j \geq 1 \), then \( \rho \) is a \( n \)-weight function. In both cases, \( L_0 \setminus \{ 0 \} \) is the set of unities of \( R \).

4. **Well-Agreeing n-weights**

The subject matter of this section can be applied to finitely many \( n \)-weight functions. However, for simplicity we shall consider the case of just two \( n \)-weights. Then, let \( \rho, \sigma \) be two \( n \)-weights on \( R \). We consider the following subsemigroup of \( (\mathbb{N}_0^2, +) \):

\[ H(\rho, \sigma) = \{ (\rho(f), \sigma(f)) : f \in R \setminus \{ 0 \} \}. \]

It can have, or have not, a finite genus.

**Proposition 4.1.** If \( H(\rho, \sigma) \) has a finite genus, then \( \rho(R \setminus \{ 0 \}) = \mathbb{N}_0 \) and \( \sigma(R \setminus \{ 0 \}) = \mathbb{N}_0 \).
Proof. Let \( n \in \mathbb{N}_0 \). The set \( \{(n, m) \notin H(\rho, \sigma) : m \in \mathbb{N}_0 \} \) is finite, hence \( n \in \rho(R) \).

Analogously for \( \sigma \).

In what follows we shall assume that \( H(\rho, \sigma) \) has a finite genus. As said before, both \( U_\rho \) and \( U_\sigma \) are subalgebras of \( R \). Then, the sets

\[
H(\sigma) := \sigma(U_\rho^*) = \{ m : (0, m) \in H(\rho, \sigma) \} \quad \text{and} \quad H(\rho) := \rho(U_\sigma^*) = \{ m : (m, 0) \in H(\rho, \sigma) \}
\]

are numerical semigroups. Write \( H(\sigma) = \{ 0 = m_0 < m_1 < m_2 < \ldots \} \).

**Lemma 4.2.** The semigroups \( H(\sigma) \) and \( H(\rho) \) have at most the genus of \( H(\rho, \sigma) \).

**Proof.** Note that \( H(\sigma) = \sigma(U_\rho \cap M_\sigma) \cup \{ 0 \} \). Now if \( \ell \) is a gap of \( H(\sigma) \), then \((0, \ell)\) is a gap of \( H(\rho, \sigma) \). The same argument for \( H(\rho) \). \( \square \)

**Proposition 4.3.** Let \( f_0 = 1 \) and for \( i \in \mathbb{N} \) take functions \( f_i \in R \), \( g_i \in U_\rho \) such that \( \rho(f_i) = i \), \( \sigma(g_i) = m_i \). Set \( \mathcal{B} := \{ f_i : i \in \mathbb{N}_0 \} \cup \{ g_j : j \in \mathbb{N} \} \subseteq R \). If \( U_\rho \cap U_\sigma = \mathbb{F} \), then \( \mathcal{B} \) is a basis of \( R \) as a \( \mathbb{F} \)-vector space.

**Proof.** We first show that \( \mathcal{B} \) is a linearly independent set. If \( \lambda_0 f_0 + \ldots + \lambda_r f_r = \mu_1 g_1 + \ldots + \mu_s g_s \), then

\[
\rho(\lambda_0 f_0 + \ldots + \lambda_r f_r) = \rho(\mu_1 g_1 + \ldots + \mu_s g_s) = 0,
\]

by (N2) and \( g_j \in U_\rho \). Then \( \lambda_i = 0 \) for \( i \geq 1 \) by \( 3.6(3) \), and so

\[
-\lambda_0 + \mu_1 g_1 + \ldots + \mu_s g_s = 0.
\]

As above it follows that \( \mu_1 = \ldots = \mu_s = 0 \) and so \( \mathcal{B} \) is in fact a linearly independent set.

We show next that \( \mathcal{B} \) generates \( R \). Let \( h \in R \) such that \( \rho(h) = i \in \mathbb{N}_0 \). By applying iteratively (N4), there exist elements \( \lambda_1, \ldots, \lambda_r \in \mathbb{F} \) such that

\[
\tilde{h} := h - \lambda_1 f_1 - \ldots - \lambda_r f_r \in U_\rho.
\]

Let \( \sigma(\tilde{h}) = m_s = \sigma(g_s) \). Arguing as above, we find elements \( \beta_1, \ldots, \beta_s \in \mathbb{F} \) so that

\[
\tilde{h} - \beta_1 g_1 - \ldots - \beta_s g_s \in U_\sigma.
\]

The proof now follows by the hypothesis \( U_\rho \cap U_\sigma = \mathbb{F} \). \( \square \)

**Definition 4.4.** We say that the n-weights \( \rho \) and \( \sigma \) agree well if the semigroup \( H(\rho, \sigma) \) has a finite genus and \( U_\rho \cap U_\sigma = \mathbb{F} \).

**Example 4.5.** (Continuation of Example 3.5) Let \( \mathcal{X} \) be a curve of genus \( \gamma \) over \( \mathbb{F} \) and let \( Q_1, Q_2 \) be two rational points. Let \( R = R(Q_1, Q_2) \) and \( \rho, \sigma \) be the n-weights associated to the points \( Q_1, Q_2 \) respectively. Then \( H(\rho, \sigma) \) is just the Weierstrass semigroup at \( Q_1, Q_2 \), \( H(\rho, \sigma) = H(Q_1, Q_2) \). By the Riemann-Roch theorem this semigroup has finite genus. Furthermore since \( U_\rho \) (resp. \( U_\sigma \)) is the set of rational functions having poles only at \( Q_2 \) (resp. at \( Q_1 \)), then \( U_\rho \cap U_\sigma = \mathbb{F} \), hence \( \rho \) and \( \sigma \) agree well. Moreover, it is easy to see
that $H(\rho) = H(Q_1)$ and $H(\sigma) = H(Q_2)$. In this case (n-weights associated to points on a curve), both semigroups have the same genus, $\gamma$. As we shall see next, this is also true for general well agreeing n-weights; see Corollary 4.8.

If the n-weights $\rho$ and $\sigma$ agree well, then the functions $f_i$ in the basis $\mathcal{B}$ can be taken in such a way that (cf. [14])

\begin{equation}
(4.1) \quad \sigma(f_i) = \min \{ \sigma(f) : f \in \mathcal{R} \text{ and } \rho(f) = i \}.
\end{equation}

**Definition 4.6.** A basis with the property above will be called *good* (with respect to the n-weights $\rho$ and $\sigma$).

The next proposition and its corollary states some properties of good basis.

**Proposition 4.7.** Let $\rho$ and $\sigma$ be two well agreeing n-weights on $\mathcal{R}$ and let $\mathcal{B} = \{ f_i : i \in \mathbb{N}_0 \} \cup \{ g_j : j \in \mathbb{N} \}$ be a good basis. Then

1. For all $i = 0, 1, \ldots$, either $\sigma(f_i) = 0$ or $\sigma(f_i)$ is a gap of $H(\sigma)$;
2. Conversely, for every gap $m$ of $H(\sigma)$ there exists exactly one index $i$ such that $\sigma(f_i) = m$;
3. $\sigma(f_i) = 0$ if and only if $i$ is a nongap of $H(\rho)$.

**Proof.**

1. Suppose that $\sigma(f_i) = m_j \in H(\sigma)$, $m_j \neq 0$; then $\sigma(f_i) = \sigma(g_j)$ and by (N4) there exists $\mu_j \in \mathbb{F}^*$ such that $\sigma(f_i - \mu_j g_j) < m_j$. Proceeding iteratively in this way we find a $\tilde{f}_i := f_i + \sum_j \mu_j g_j$ such that $\sigma(\tilde{f}_i) \in \text{Gaps}(H(\sigma)) \cup \{0\}$. Since $\rho(\tilde{f}_i) = \rho(f_i) = i$ by Lemma 2.1(5), the proof is complete.

2. Let $t \in \mathbb{N}$ be a gap of $H(\sigma)$. Let us prove first that there are at most one $r$ such that $\sigma(f_r) = t$. If, on the contrary, $\sigma(f_i) = \sigma(f_j) = t$ for some $i > j$, then there is a $\lambda \in \mathbb{F}^*$ such that $\sigma(f_i - \lambda f_j) < m$. Then $f_i = f_i - \lambda f_j$ verifies $\rho(f_i) = i$, contradicting the defining property of the function $f_i$. Let us prove now that there is an index $r$ such that $\sigma(f_r) = t$. From [4.1] there is $h \in \mathcal{R}$ such that $\sigma(h) = m$. Write

\[ h = \sum_{i \in I} \lambda_i f_i + \sum_{j \in J} \mu_j g_j. \]

with $I \subseteq \mathbb{N}_0$, $J \subset \mathbb{N}$ and $\lambda_i, \mu_j \neq 0$. Since all the elements in the family $\{ \sigma(f_i) : i \in I, \sigma(f_i) \neq 0 \}$ are pairwise distinct gaps of $H(\sigma)$, and all the elements in the family $\{ \sigma(g_j) : j \in J \}$ are pairwise distinct nongaps of $H(\sigma)$, according to the properties of n-weights, we conclude that

\[ t = \sigma(h) = \max(\{ \sigma(f_i) : i \in I \} \cup \{ \sigma(g_j) : j \in J \}) = \sigma(f_r) \]

for some $r$ (because $m$ is a gap).

3. $\sigma(f_i) = 0$ if and only if there exists $f \in \mathcal{U}_\sigma$ with $\rho(f) = i$, that is, if and only if $i$ is a nongap of $H(\rho)$. \(\square\)
Corollary 4.8. Let $\rho$ and $\sigma$ be two well agreeing $n$-weights on $R$ and let $B$ be a good basis. Then

(1) $\sigma(f_i)$ is a gap of $H(\sigma)$ if and only if $i$ is a gap of $H(\rho)$. In particular, both semigroups have equal genus.

(2) $\sigma(f_i) = 0$ except for finitely many $i$’s; for all $i$, $\sigma(f_i) \leq \Lambda_\sigma$, where $\Lambda_\sigma$ is the largest gap of $H(\sigma)$.

Well agreeing $n$-weights and good basis can be used to construct codes from $R$, as we shall see in the next Section.

5. The Codes and a Bound on the Minimum Distance

5.1. N-order Codes. Let $\rho, \sigma$ be two well agreeing $n$-weights on a $\mathbb{F}$-algebra $R$ and let $B := \{f_i : i \in \mathbb{N}_0\} \cup \{g_j : j \in \mathbb{N}\}$ be a good basis. Let $\gamma$ be the genus of $H(\sigma)$ (or equivalently the genus of $H(\rho)$) and $\Lambda_\sigma$ its largest gap. For a pair of non-negative integers $\ell, m \in \mathbb{N}_0$, set $a$ to be the (only) integer such that

$$m_a \leq m < m_{a+1}$$

and let us consider the set

$$R^m_\ell = \{h \in R : \rho(h) \leq \ell \text{ and } \sigma(h) \leq m\}.$$  

Proposition 5.1. $R^m_\ell$ is a vector subspace of $R$. Furthermore, if $m \geq \Lambda_\sigma$ then

$$R^m_\ell = (f_0, \ldots, f_\ell, g_0, g_1, \ldots, g_a),$$

where $g_0 = f_0 = 1$. In this case $\dim(R^m_\ell) = \ell + m + 1 - \gamma$.

Let $\ast$ denote the product in $\mathbb{F}^n$ defined by the coordinatewise multiplication, and let $\varphi : R \to \mathbb{F}^n$ be a morphism of $\mathbb{F}$-algebras. Let $m$ be an integer such that $m \geq \Lambda_\sigma$ and $\varphi(\cup_\ell R^m_\ell) = \mathbb{F}^n$. We define the codes

$$(5.1) \quad E^m_\ell := \varphi(R^m_\ell) \quad \text{and} \quad C^m_\ell := (E^m_\ell)^{\perp}.$$  

Note that, since $\varphi(\cup_\ell R^m_\ell) = \mathbb{F}^n$, there exists $L$ such that $E^m_0 \subseteq E^m_1 \subseteq \ldots \subseteq E^m_L = \mathbb{F}^n$ and hence $C^m_0 \supseteq C^m_1 \supseteq \ldots \supseteq C^m_L = (0)$.

Example 5.2. (Continuation of Example 4.5) Let $\mathcal{X}$ be a curve of genus $\gamma$ over $\mathbb{F}$ and let $Q_1, Q_2$ be two rational points. Let $R = R(Q_1, Q_2)$ and $\rho, \sigma$ be the $n$-weights associated to the points $Q_1, Q_2$ respectively. Since $R^m_\ell = L(Q_1 + mQ_2)$, if we take a divisor $D = P_1 + \cdots + P_n$, sum of $n$ distinct rational points on $\mathcal{X}$ and $\varphi = ev$, the evaluation at these points, we obtain the codes $E^m_\ell = C_L(\mathcal{X}, D, \ell Q_1 + mQ_2)$ and $C^m_\ell = C_\Omega(\mathcal{X}, D, \ell Q_1 + mQ_2)$.

The dimension of $E^m_\ell$ and $C^m_\ell$ depends on the dimension of the subspaces $R^m_\ell$ and the morphism $\varphi$. With regard to their minimum distances, we shall show a bound on the minimum distance of $C^m_\ell$, analogous to the order bound in [S Section 4].
5.2. The n-order bound on the minimum distance. For a vector \( y \in \mathbb{F}^n \) and \( i, j = 0, \ldots, L \), let us consider the two-dimensional syndromes

\[
s_{ij}(y) = (h_i \ast h_j) \cdot y,
\]

where \( h_i = \varphi(f_i) \). The matrix of syndromes of \( y \) is \( S(y) = (s_{ij}(y))_{i,j=0,\ldots,L} \).

**Proposition 5.3.** \( \text{wt}(y) \geq \text{rank}(S(y)) \).

**Proof.** Analogous to [8, Lemma 4.7]. \( \square \)

For a nonnegative integer \( s \), set

\[
\Sigma(s) = \max\{\sigma(f_0), \ldots, \sigma(f_s)\}, \quad \text{and}
\]

\[
N^m_\ell = \{(i, j) \in \mathbb{N}^2 : i + j = \ell + 1 \text{ and } \sigma(f_i) + \Sigma(j) \leq m\}.
\]

Note that for all \( i, j \), it holds that \( \rho(f_i f_j) = \rho(f_i) + \rho(f_j) \). Thus, if \( (i, j) \in N^m_\ell \) then \( f_i f_j \in \mathbb{R}^{m+1}_{\ell+1} \setminus \mathbb{R}^m_\ell \).

**Proposition 5.4.** Write \( N^m_\ell = \{(i_1, j_1), \ldots, (i_t, j_t)\} \) ordered in increasing lexicographical order. Then

1. \( i_1 < \ldots < i_t \) and \( j_1 > \ldots > j_t \);
2. If \( y \in C^n_\ell \) and \( u < v \), then \( s_{i_u,j_u}(y) = 0 \);
3. If \( y \in C^n_\ell \setminus C^n_{\ell+1} \), then \( s_{i_u,j_u}(y) \neq 0 \).

**Proof.** (1) Note that \( i_u + j_u = \ell + 1 \).

(2) Since \( j_v < j_u \), then \( \rho(f_{i_u}) + \rho(f_{j_u}) < \rho(f_{i_v}) + \rho(f_{j_v}) = \ell + 1 \) and \( \sigma(f_{i_u}) + \sigma(j_u) \leq m \). Thus \( f_{i_u} f_{j_v} \in R^m_\ell \), hence \( h_{i_u} \ast h_{j_v} \in E^m_\ell \) and \( (h_{i_u} \ast h_{j_v}) \cdot y = 0 \).

(3) Since \( f_{i_u} f_{j_v} \in R^m_\ell \setminus R^m_{\ell+1} \), then \( f_{i_u} f_{j_v} = \lambda f_{\ell+1} + f \) with \( \lambda \neq 0 \) and \( \rho(f) \leq \ell \). Furthermore, since \( m \geq \Lambda_\sigma \) it holds that \( \sigma(f) \leq m \), hence \( f \in R^m_\ell \). Then \( h_{i_u} \ast h_{j_v} = \lambda h_{\ell+1} + h \), with \( h \in E^m_\ell \), so \( (h_{i_u} \ast h_{j_v}) \cdot y = \lambda h_{\ell+1} \cdot y \neq 0 \). \( \square \)

**Corollary 5.5.** If \( y \in C^n_\ell \setminus C^n_{\ell+1} \), then \( \text{rank}(S(y)) \geq \#N^m_\ell \).

**Proof.** The minor obtained from \( S(y) \) by taking the rows \( i_1 < \ldots < i_t \) and the columns \( j_1 > \ldots > j_t \) is nonsingular. \( \square \)

**Definition 5.6.** The n-order bound on the minimum distance of \( C^n_\ell \) is defined as

\[
d_{\text{NORD}}(\ell, m) := \min\{\#N^m_r : r \geq \ell\}.
\]

As a direct consequence of the above results we have the following.

**Theorem 5.7.** The minimum distance of the code \( C^n_\ell \) is lower bounded by \( d_{\text{NORD}}(\ell, m) \), that is

\[
d(C^n_\ell) \geq d_{\text{NORD}}(\ell, m).
\]
Next we shall give a bound on the cardinality $\#N^m_r$.

**Proposition 5.8.** We have $\#N^m_r \geq \#(H(\rho) \cap [1, r + 1])$. In particular, if $r \geq \gamma$ then $\#N^m_r \geq r - \gamma + 1$.

**Proof.** If $i \in H(\rho) \cap [1, r + 1]$ then, according to 4.7 (3), it holds that $\sigma(f_i) = 0$, hence $(i, r + 1 - i) \in N^m_r$ (because $\Sigma(r + 1 - i) \leq \Lambda_\sigma \leq m$). Since $H(\rho)$ is a semigroup of genus $\gamma$ then $\#(H(\rho) \cap [1, r + 1]) \geq r - \gamma + 1$ for $r \geq \gamma$. □

**Corollary 5.9.** If $\ell \geq \gamma$, then $d(C^m_\ell) \geq d_{NORD}(\ell, m) \geq \ell - \gamma + 1$.

As another consequence of the proposition, the computation of $d_{NORD}(\ell, m)$ only requires the knowledge of a finite number of terms $\#N^m_r$.

**Corollary 5.10.** $d_{NORD}(\ell, m) = \min\{\#N^m_\ell, \ldots, \#N^m_{\ell + \gamma}\}$.

**Proof.** Note that $\#N^m_r \leq r + 2$ by definition. Thus, according to the above proposition, if $r > \ell + \gamma$ then $\#N^m_r \geq \ell + 2 \geq \#N^m_\ell$ and hence $\min\{\#N^m_r : r \geq \ell\}$ must be attained in the set $\{\#N^m_\ell, \ldots, \#N^m_{\ell + \gamma}\}$. □

**Remark 5.11.** Note that the n-order bound does not depend on the good basis chosen. In fact, since 4.1 is equivalent to

$$\sigma(f_i) = \min\{t \in \mathbb{N}_0 : (i, t) \in H(\rho, \sigma)\},$$

each $\#N^m_r$ (and hence $d_{NORD}(\ell, m)$) can be computed, in finite time, from only the information given by the semigroup $H(\rho, \sigma)$.

### 5.3. Performance of the n-order bound

Next we study the performance of the obtained bound. To that end we shall compare it to the Goppa bound, $d_G(\ell, m) := \ell + m - 2\gamma + 2$ by means of the number

$$\Delta(\ell, m) := d_{NORD}(\ell, m) - d_G(\ell, m).$$

Remark that when the code $C^m_\ell$ is obtained from two points on an algebraic curve, $C^m_\ell = C_\Omega(\mathcal{X}, D, \ell Q_1 + m Q_2)$, then its minimum distance verifies $d(C^m_\ell) \geq d_G(\ell, m)$.

Let $\Lambda_\rho$ and $\Lambda_\sigma$ be the largest gaps of $H(\rho)$ and $H(\sigma)$ respectively. Furthermore, let $s$ be the integer defined by

$$\sigma(f_s) = \max\{\sigma(f_i) : i \in \mathbb{N}\} = \Lambda_\sigma = c_\sigma - 1.$$

For large values of $m$ the n-order bound is easy to compute.

**Lemma 5.12.** If $m \geq 2\Lambda_\sigma$, then $d_{NORD}(\ell, m) = \ell + 2$. In particular, $\Delta(\ell, m) = 2\gamma - m$, hence $\Delta(\ell, m) < 0$ for $m > 2\gamma$ and $d_{NORD}(\ell, m) = d_G$ if and only if $m = 2\gamma$ (and thus $\Lambda_\sigma = \gamma$).
Thus, the remaining case to study is $\Lambda_\sigma \leq m < 2\Lambda_\sigma$. Write

$$N_r^m = \{(0, r + 1), (r + 1, 0)\} \cup \{(i, j) \in \mathbb{N}^2 : i \in A_r^m \cup B_r^m \cup C_r^m\},$$

where

$$A_r^m = H(\rho) \cap [1, r],$$

$$B_r^m = \{i \in \text{Gaps}(H(\rho)) \cap [1, r + 1 - s] : \sigma(f_i) + \Lambda_\sigma \leq m\} \quad \text{and}$$

$$C_r^m = \{i \in \text{Gaps}(H(\rho)) \cap [r + 2 - s, r] : \sigma(f_i) + \Sigma(r + 1 - i) \leq m\}.$$

The following lemma holds true.

**Lemma 5.13.** Assume $\Lambda_\sigma \leq m < 2\Lambda_\sigma$ and let $\ell \geq \Lambda_\rho + s - 1$. Then

1. $d_{\text{NORD}}(\ell, m) = \ell + 2 - \gamma + \#A_r^m$;
2. If $\Lambda_\sigma \geq \gamma + 1$, then $d_{\text{NORD}}(\ell, m) < d_G(\ell, m)$;
3. $d_{\text{NORD}}(\ell, m) = d_G(\ell, m)$ if and only if $\Lambda_\sigma = \gamma$.

**Proof.**

(1) We have $r \geq \Lambda_\rho + 1$ for $r \geq \ell$; on the other hand, $\ell + 2 - s \geq \Lambda_\rho + 1$ and the proof follows from the fact that $\#A_r^m$ increases with $r$.

(2) By (1), and since $\#A_r^m \leq m - \Lambda_\sigma$, we have $\Delta(\ell, m) = \gamma + \#A_r^m - m \leq \gamma - \Lambda_\sigma$.

(3) If $\Delta(\ell, m) = 0$, then clearly $\Lambda_\sigma = \gamma$. Conversely, if $\Lambda_\sigma = \gamma$, then $\#A_r^m = m - \gamma$. \qed

After this lemma, one may expect to obtain $\Delta(\ell, m) > 0$ only in the case

$$\Lambda_\sigma \leq m < 2\Lambda_\sigma \quad \text{and} \quad \ell \leq \Lambda_\rho + s - 2.$$  

In fact, this can occur as the next example shows.

**Example 5.14.** Suppose $\sigma(f_i) = i$ for $i = 1, \ldots, \gamma$ (this case can occur on points of the Hyperelliptic curve, see [9]). Then $H(\rho) = \{\gamma + 1, \gamma + 2, \ldots\}$ and $s = \gamma$. Take $\gamma \leq m < 2\gamma$ and $\ell \geq \gamma + 1$; thus for $r \geq \gamma$

$$\#N_r^m = r + 2 - \gamma +$$

$$\#\{i \in [1, r + 1 - \gamma] \cap \text{Gaps}(H_\rho) : i + \gamma \leq m\} +$$

$$\#\{i \in [r + 2 - \gamma, r + 1] \cap \text{Gaps}(H_\rho) : i + \Sigma(r + 1 - i)\}.$$

Since $m < \gamma$,

$$\#N_r^m = r + 2 - \gamma + \min\{r + 1 - \gamma, m - \gamma\} + c(m, r),$$

where $c(m, r) = 0$ if $r + 1 > m$ and $c(m, r) = 2\gamma - r - 1$ if $r + 1 \leq m + 1$. Thus

$$\#N_r^m = \begin{cases} r + m - 2\gamma + 2 & \text{if } r + 1 > m, \\ r + 2 & \text{if } r + 1 \leq m. \end{cases}$$
Observe that $\#N^m_\ell = d_G(\ell, m)$ if $\ell + 1 > m$ and $\#N^m_\ell > d_G(\ell, m)$ otherwise. Thus $d_{ORD}(\ell, m)$ is greater than $d_G(\ell, m)$ whenever $\gamma \leq \ell < m < 2\gamma$.

Finally, for the case $\gamma < m < 2\gamma$ and $\ell < \gamma$, a direct computation shows that $\#N^m_r = r + 2$ and hence the n-order bound on the minimum distance improves also on the Goppa bound.
