Regioselective/electro-oxidative intermolecular [3 + 2] annulation for the preparation of indolines†

Qingqing Wang,† Pan Wang,† Xinlong Gao, Dan Wang, Shengchun Wang, Xingan Liang, Liwei Wang, Heng Zhang, and Aiwen Lei*†a,b

Compared with the reported intramolecular electro-oxidative cyclization of alkenyl amines or vinyl anilines for the preparation of pyrrolidines or indolines, the intermolecular version is less studied. Herein, this electrochemical intermolecular oxidative annulation of anilines and alkenes for the preparation of indolines proceeded under external oxidant-free conditions. The most noteworthy achievement of our work is the facile generation of indolines with quaternary centers at the 2-position. In addition, alkenes and anilines bearing various functional groups can be well tolerated. Remarkably, electrolyte-free conditions were used in an electrochemical flow cell, which shows the application potential of this method.

Introduction

Indole derivatives are the core skeletons widely found in natural products, pharmaceuticals and functionalized materials, such as physosovenine, vallesamidine, indapamide and cannabinoid receptor modulators. In recent years, substantial effort has been made to develop efficient methods for the synthesis of indolines. The dearomatization of indoles is the classical method to synthesize indolines. In addition, transition metal-catalyzed dehydrogenative C–H/N–H coupling reactions to synthesize indolines via inter- or intramolecular annulation have occupied a predominant position. Despite major progress in this field, stoichiometric amounts of oxidants such as Cu(ii), Ag(i), benzoquinone (BQ) or selectfluor (with or without transition metal catalysts) are generally required. Under these reaction conditions, toxic or undesirable byproducts are not avoidable. It is more appealing to develop external oxidant-free reaction protocols to access indoline derivatives directly based on the rule of atom economy and sustainable chemistry.

Electrochemical oxidation offers an efficient and mild alternative to the use of hazardous chemical oxidants and sometimes demonstrates unique reaction selectivity compared with chemical oxidation. Besides, electro-oxidation-induced direct C–H bond functionalization might be an efficient and environmentally friendly strategy to construct C–C and C–X bonds. Many methods have been developed to synthesize functionalized indolines. Among them, electrosynthesis methods can significantly reduce pollution. In the seminal studies on electrochemical cyclization of alkenyl amines, electro-oxidative coupling reactions have provided pyrrolidines or lactams under mild conditions either through direct electrolysis or using redox catalysts (Scheme 1a). However, these studies have focused on intramolecular C–N coupling. It is very difficult to achieve intermolecular annulation for the synthesis of indolines. Herein, we report a versatile regioselective/electro-oxidative intermolecular [3 + 2] annulation method under oxidant-free conditions to synthesize substituted indolines (Scheme 1b).

Results and discussion

Our studies commenced with N-(4-methoxyphenyl)-4-methylbenzenesulfonylamine (1a) and α-methylstyrenes (2a) (Table 1). The reaction was carried out in an undivided cell under constant current electrolysis (CCE) with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ, 10 mol%) and Bu4NBF4 as...
Remarkably, thiophene derivative products yields. Notably, the electrophilic functional groups, such as converted to the corresponding indolines methylstyrenes reaction took place without electric current under an air plate was applied as the cathode which furnished 5N a2CO3 instead of HOAC 62 BQ instead of DDQ 61 No HOAc 54 No DDQ 45 3a.

Increasing the operating current (entries 8 and 9). In order to slightly lower yields were obtained by either decreasing or acetonitrile or 1,2-dichloroethane (entries 6 and 7). In addition, No electric current (entry 5). Thereafter, the solvent effect was also explored. Inferior reactivity could be observed by using acetonitrile or 1,2-dichloroethane (entries 6 and 7). In addition, slightly lower yields were obtained by either decreasing or increasing the operating current (entries 8 and 9). In order to test the electrode effect, carbon cloth, a nickel plate, or an iron plate was applied as the cathode which furnished 3aa in 57–78% yields (entries 10–12). The reaction yield decreased dramatically when the reaction was opened to air (entry 13). No reaction took place without electric current under an air atmosphere (entries 14 and 15).

With the optimized reaction conditions in hand, we screened the substrate scope of alkenes (Scheme 2). Various α-methylstyrenes 2b–2i with meta- or para-substitution could be converted to the corresponding indolines 3ab–3ai in 61–95% yields. Notably, the electrophilic functional groups, such as fluoro, chloro, and bromo, were well tolerated. Gratifyingly, 6-methyl-1-methylene-2,3-dihydro-1H-indene (2j) also reacted efficiently to obtain the spiroindoline derivative (3aj, 62%). Remarkably, thiophene derivative 2k and 2-iso-propenynaphthalene (2l) reacted with anilines to furnish final products 3ak–3al in good to moderate yields. Importantly, diene 2m underwent selective electro-oxidative [3 + 2] annulation smoothly, giving the mono-cyclization product 3am in 53% yield. Subsequently, α-alkylstyrenes bearing linear or cyclic alkyl groups 2n–2p proved to be suitable substrates, and the desired indolines 3an–3ap were isolated in 81–93% yields. Additionally, 1,1-diphenylethylene derivatives 2q–2u were converted to the corresponding 2,2-diarylidolines which were difficult to access because of significant steric issues. To our delight, the desired products 3aq–3au were formed in high yields. Moreover, the reaction could be extended to styrenes 2v–2x and afforded the indoline products 3av–3ax in 59–78% yields. Notably, this method could also be efficiently extended to (E)-1,2-diphenylethene to afford the 2,3-fused indolines (3ay). Moreover, other olefins (e.g. alkyl olefins) have been tried, but only a trace amount of the desired products could be obtained (Scheme S4†).

Subsequently, the scope of anilines was explored (Scheme 3). The strong electron-rich substituted amines 4-methyl-N-(4-(methylthio)phenyl)benzenesulfonylamine 1b and N-(benzo[d][1,3]dioxol-5-yl)-4-methylbenzenesulfonylamine 1c could be tolerated to obtain the products 3ba and 3ca in high yield under constant current electrolysis. As for the reaction of N-(4-(tert-
butyl) phenyl]-4-methylbenzenesulfonamide (3d), low yield was obtained. At the same time, considering the electronic effect, we have also made efforts to try other substituted amines in an undivided cell under constant current or constant voltage electrolysis. We found that a trace amount of products could be monitored in these reactions (Scheme S2†). When substituted N-tosylanilines 1e–1i were used, indolines 3ea–3ia were obtained in good yields (58–82%). Subsequently, we speculated that applying a sulfonyl group as the protecting group might be helpful in manipulating reactivity. Therefore, different N-sulfonylanilines 1j–1p were prepared and well tolerated under the standard reaction conditions, giving indolines 3ja–3pa in high yields (66–84%). Except for N-Ts, anilines with other protecting groups (1q and 1r) have been tried, which could give the desired products 3qa and 3ra in 53% and 56% yields.

Recently, electrochemical flow cells have been successfully used in a variety of organic transformations.9–16 Considering the difficulty of electrolyte post-treatment and the price of electrolytes, we tried to achieve this transformation in flow cells in the absence of the electrolyte. Gratifyingly, indoline derivatives could be obtained under electrolyte-free conditions in the presence of only 5 mol% DDQ, which shows the application potential of this method (Scheme 4). Various alkenes (e.g. α-methylstyrenes, styrene, 1,1-diphenylethylene derivatives, and heterocyclic olefin) could be well tolerated.

To further demonstrate the utility of the electrochemical method, the scale-up reaction was carried out in the 5 mmol scale. Considering the price of platinum electrodes, a nickel plate was employed as the cathode. In a continuous-flow reactor, indoline 3aa could be obtained in 65% yield with a good selectivity and efficiency in a gram scale synthesis (Scheme 5a). Furthermore, the optimized conditions were applied to electro-

Scheme 6 The deprotection of the N-Ts and N-Boc group.
oxidative $[3 + 2]$ annulation in an undivided cell in the 5.0 mmol scale. Thus, indoline 3aa could be obtained in 80% yield (Scheme 5b).

Moreover, as illustrated in Scheme 6, deprotection of the $N$-Ts or $N$-Boc group proceeded smoothly to separately give 2-methyl-2-phenylindoline (4a) in 99% and 95% yields on a larger scale (up to 5.5 mmol). Disubstituted indolines possess a significant synthetic value in medicinal chemistry. Interestingly, we envisioned that the oxidative dehydrogenation of indoline (3aw) may achieve the 2-position indole derivative (4b) in 69% yield by a one pot two-step method in the same undivided cell under constant current electrolysis without separation of 3aa (Scheme 7).

In order to clarify the reaction pathway of this reaction, some control experiments were carried out as shown in Scheme 5. When (2,2,6,6-tetramethylpiperidin-1-yl)oxyl (TEMPO, 1 equiv.) was added into the reaction between 1a and 2a under the standard conditions, no desired product was observed (Scheme 8a). Thus, this transformation was proposed to proceed via a radical pathway. Then 5.0 equiv. of triethyl phosphate was added to the reaction mixture to trap the radical intermediates. Interestingly, the phosphorylation product 4c was obtained in 50% yield, which suggested the generation of a carbon radical during the reaction (Scheme 8b). Moreover, in the absence of 2a and DDQ, the homocoupling product 4d could be obtained with the formation of 4e in 53% yield at the same time, which suggested that nitrogen radicals were generated and then transformed into carbon radicals subsequently (Scheme 8c). Furthermore, electron paramagnetic resonance (EPR) experiments were carried out when electrolysis was performed for 30 minutes in the absence of styrene 2a and DDQ. The EPR spectra show that an organic conjugated radical is formed (see Fig. S1†). Therefore, the above control experiments and EPR results might reveal the existence of a carbon radical intermediate under the reaction conditions.

To gain a deeper insight into the mechanism of this transformation, cyclic voltammetry (CV) experiments were conducted. First, as shown in Fig. 1a, no obvious oxidation peak was observed for $z$-methylstyrenes 2a in the region of 0.0–2.0 V vs. Ag/AgCl. However, $N$-(4-methoxyphenyl)-4-methylbenzenesulfonamide 1a gave an oxidation wave at 1.49 V vs. Ag/AgCl. The results suggested that 1a was easier to oxidize than 2a. However, the electrochemical behavior of 1a did not change in the presence of HOAc, indicating that HOAc may mainly serve as a proton source for hydrogen evolution. However, when $z$-methylstyrene 2a was added, a catalytic current was observed, which showed radical addition between 1a and alkene 2a (Fig. 1a, the red line). Moreover, when DDQ was added, a slight catalytic current was observed; the peak currents of Ox1 and Ox2 increased slightly from 16.8 to 17.9 μA, which indicated that aniline 1a was not mainly oxidized by DDQ. In other words, it may only mean that the reaction was slow and did not occur at the electrode surface (see Fig. S3†). Furthermore, UV experiments also demonstrated that there was no interaction between DDQ and 1a (Fig. 1b).

In addition, kinetic studies of this reaction were carried out by detecting the initial rate with different concentrations of 1a and 2b by HPLC analysis. The reaction demonstrated a first order dependence on 1a and was independent of the concentration of 2b, which indicated that the anodic oxidation of 1a may be the rate determining step (for details see Fig. S5†).

Scheme 7 One pot two-step process for 2-position indole synthesis.

Scheme 8 Mechanistic studies.

Scheme 9 Proposed mechanism.
Based on the experimental results and literature reports, a plausible mechanism is outlined in Scheme 9. The reaction is initiated by the anodic oxidation of aniline 1a. The subsequent deprotonation can produce N-radical species I, which can resonate to liberate the C-radical species II. Intermediate III can be formed through the radical addition between II and alkene 2a. Subsequently, intermediate III is oxidized either through anodic oxidation or by DDQ. Finally, the target molecule 3aa is generated through the intermolecular cyclization. Concomitant cathodic reduction of the proton leads to the formation of dihydrogen.

Conclusions

In conclusion, we have developed a novel method for the electrochemical intermolecular [3 + 2] annulation of anilines and alkenes. This method was external oxidant-free, which provided a simple and atom-economic way to synthesize functionalized indolines. A wide range of functional groups proved to be compatible under our optimized conditions. Besides, in the absence of electrolyte, indolines could be obtained in the electrochemical flow cell, which shows the great application potential of this method. Control experiments and mechanistic studies suggested that a carbon radical was involved in the reaction pathway.

Experimental

General procedure for regioselective/electro-oxidative intermolecular [3 + 2] annulation for the preparation of indolines

An undivided cell was equipped with a carbon anode and a platinum cathode and connected to a DC regulated power supply. N-(4-Methoxyphenyl)-4-methylbenzenesulfonamide (0.20 mmol), prop-1-en-2-ylbenzene (0.40 mmol), Bu4NBF4 (0.1 M), 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (0.02 mmol), AcOH (0.2 mmol) and CH3CN/DCE (4/2 mL) were combined and added. The bottle was equipped with a graphite electrode as the cathode and a platinum electrode (1.5 \times 1.5 \times 0.3 \text{ cm}^3) as the anode. The reaction mixture was stirred and electrolyzed at a constant current of 10 mA for 2.0 h. When the reaction was finished, the solution was extracted with EtOAc (3 \times 10 \text{ mL}) and H2O (3 \times 10 \text{ mL}). The combined organic layer was dried with Na2SO4 and filtered. The solvent was removed with a rotary evaporator. The pure product was obtained by flash chromatography on silica gel using petroleum ether and ethyl acetate as the eluent (10 : 1).
