Abstract:

Osteoblast cells are responsible for synthesizing new bone tissue, and determining how to control osteoblastic differentiation is vital to the treatment of osteoporosis. In this study, we show that pentraxin 3 (PTX3) signaling is involved in the regulation of osteoblastic differentiation in MC3T3-E1 cells. Our data reveal that PTX3 is abundantly expressed in MC3T3-E1 cells and that its expression is inducible by the introduction of osteogenic induction medium (OIM). Overexpression of PTX3 was observed to significantly increase the expression of four osteoblast signature genes, including runt-related transcription factor 2 (RUNX2), alkaline phosphatase (ALP), osteocalcin (OCN) and osterix (OSX), suggesting that the overexpression of PTX3 promotes osteoblastic differentiation. The relative level of gene expression between OIM and OIM plus overexpressed PTX3 was evaluated using the Affymetrix Gene Chip® mouse gene microarray. PTX3-related DEGs were screened. GO functional and KEGG pathway enrichment analyses were performed, and the PI3K/Akt signaling pathway was primarily involved in the osteogenic differentiation of PTX3. Protein-protein interactions were also constructed, and the MCODE plugin calculated modules of PPI networks. Moreover, we show that the effect of PTX3 is mediated by its induction of the PI3K/Akt signaling pathway. Mechanistically, we
show that the action of PTX3 requires the activation of PI3K and Akt, and deactivation of PI3K by its inhibitor LY294002 weakens the PTX3-mediated induction of osteoblast signature genes, ALP, and matrix mineralization. This study revealed a new role played by PTX3 and suggest a potential mechanism governing the osteoblastic differentiation of MC3T3-E1 cells.

**Key words:** PTX3; MC3T3-E1 cells; PI3K/Akt; Osteogenic differentiation

### 1. Introduction

Osteoporosis is a condition in which bone becomes weak and is characterized by low bone mass and structural deterioration[1,2]. As a result, bone tissue becomes fragile and shows increased vulnerability to fracture. Worldwide, osteoporosis affects approximately 200 million people and is often unrecognized until one encounters the fracture due to the silent nature of the disease[3]. Under healthy conditions, bone is maintained by the constant process of bone remodeling[4].

Normal bone remodeling maintains a balance between bone resorption and formation to maintain bone density. Osteoblasts are generated from the osteogenic differentiation of mesenchymal stem cells (MSCs). MSCs possess the capacity to self-renew and differentiate into multiple cell types. It is known that MSCs are common precursors for osteoblasts[5]. The direction of MSC differentiation depends on specific regulatory factors. RUNX-2 acts as a key transcriptional modulator that mediates the conversion of MSCs to osteoblasts[6,7].

As osteoblasts mature, they begin producing the bone extracellular matrix by secreting bone matrix proteins, including collagen type 1 alpha 1 (Col-I), osteocalcin (OCN), and alkaline phosphatase (ALP). Type I collagen is the main constituent of bone, comprising the nonmineralized bone matrix. The accumulation of calcium phosphate in the bone matrix by ALP leads to the mineralization of bone. Mature osteoblasts express ALP, Col-I, osteocalcin, and osterix [4]. It has been recognized that the normal differentiation capacity of MSCs is altered in osteoporosis, thereby hindering osteoblast formation[5].

The PI3K/AKT signaling pathway has been shown to be critical for osteogenic differentiation, growth, and survival[8,9,10]. PI3K signaling has a positive role in
chondrocyte differentiation and is involved in the endochondral bone growth process [11]. Therefore, the PI3K/Akt signaling pathway is crucial for osteoblast differentiation.

Long pentraxin 3 (PTX3), belonging to the pentraxin superfamily, is an inflammatory mediator and plays an essential role in innate immunity and matrix remodeling. PTX3 is induced by primary pro-inflammatory cytokines in different cell types. Mice with a gene deficient in PTX3 show a lower trabecular bone volume, and PTX3 supports maintenance of the bone mass by inhibiting FGF-2 expression [12]. Chang et al. [13] further revealed that PTX3 could stimulate the PI3K/Akt signaling pathway and, in turn, induce metastasis.

Therefore, we investigated whether PTX3 could regulate osteogenic differentiation by regulating the PI3K/Akt signaling pathway in osteoblasts. The present study aimed to investigate the role of PTX3 in promoting osteogenic differentiation in MC3T3-E1 cells. The underlying mechanisms and the connection of the PI3K/Akt signaling pathway with this process were also explored in this study.

2. Materials and methods

2.1 Cell culture

The mouse pre-osteoblast cell line MC3T3-E1 was obtained from American Type Culture Collection (ATCC, CRL-2593). MC3T3-E1 cells were maintained with DMEM (Gibco, USA) supplemented with 10% FBS (Gibco), 10 mM HEPES (Sigma), and 0.1% penicillin-streptomycin (Sigma Aldrich).

2.2 Osteogenic differentiation

The differentiation of cultured MC3T3-E1 cells was induced by incubating osteogenic induction medium (OIM) containing DMEM, FBS (5%), β-glycerophosphate (3 mM), and ascorbic acid (50 μg/mL) for 0, 1, 3, 7, 14 and 28 d. Cells maintained in normal growth media were used as the control. After 14 d and 28 d of cultivation in an OIM, the alkaline phosphatase (ALP) activity and ARS were examined.

2.3 PTX3 overexpression and knockdown assay

The lentiviral expression system overexpressing PTX3 was termed Lenti-PTX3 OE. The open reading frame of mouse PTX3 (NM_602492) was synthesized and cloned into the pL/IRES/GFP plasmid (Novobio, Shanghai, China) to generate pL/IRES/GFP-PTX3. The empty lentiviral expression system without insertion was termed Lenti-CTRL and
used as the control. 293T cells were then transfected with the plasmids listed above. Transfection and lentiviral transduction were performed as described previously[14]. The siRNA sequences against PTX3 and control siRNA was purchased from ThermoFisher Scientific (ThermoFisher Scientific, Germany). Experiments with the PTX3 assay were carried out according to the manufacturer’s instructions. Concentration of si-PTX3 was 30 nM and in accordance with the previous studies[15,16].

2.4 Transcriptome sequencing

Total RNA was isolated from MC3T3-E1 cells treated in the presence of OIM with and without PTX3. Following DNA removal by digestion with DNase I (Thermo Fisher Scientific), a single strand of cDNA was first synthesized using random primers, and double-stranded cDNA was subsequently synthesized. The purified double-stranded cDNA was end-repaired, subjected to poly(A) addition and then ligated to the adapter. The cDNA library was then amplified by PCR and subjected to quality checking using an Agilent 2100 Bioanalyzer and ABI StepOnePlus Real-Time PCR System before being sequenced using an Affymetrix Gene Chip® mouse gene microarray.

2.5 Bioinformatic analysis

Gene count normalization and differential expression analysis were performed using the limma and voom package[17]. Following normalization, differentially expressed genes were identified via the R statistical package LIMMA (version 3.5.1)[18]. DEGs with screening conditions of P < 0.05 and |log2 (fold change)| > 1. Choice of DEGs list using volcano plot and heat map analysis by R software (version 3.5.1).

To explore the function of the DEGs in PTX-3-mediated osteogenic differentiation of MC3T3-E1 cells, the biological function of the DEGs was investigated by a GO enrichment analysis, which comprised 3 terms, including biological process (BP), molecular function (MF) and cellular component (CC)[19]. Pathway analysis of DEGs was performed using Kyoto Encyclopedia of Genes and Genomes database (KEGG) pathway analysis. P-values < 0.05 were considered to be significant. Protein-protein interaction (PPI) analysis between PTX-3 and neighboring genes was performed via the STRING tool (http://string-db.org/), and visualization was constructed by the enrichment map plugin in Cytoscape[20]. Combined scores > 5.0 were selected as previously described[21].
Molecular complex detection (MCODE) plug-in in Cytoscape software (http://www.cytoscape.org/) was performed to screen the modules in the PPI network. The criteria were set as follows: MCODE scores > 3, number of nodes > 3, and P-values < 0.05 were considered to be significant.

2.6 Alkaline phosphatase (ALP) activity

After reaching full confluence, the cells were equilibrated with ALPL buffer and incubated with 0.2 mg/mL nitro blue tetrazolium and 5-bromo-4-chloro-3-indolyl-phosphate (Sigma, USA). Cells were stained with ALPL buffer at room temperature for 2 hours. The fluorescent signal was measured using a microplate reader (405 nm). The results are expressed as percentage changes in relation to the control group.

2.7. Alizarin Red S (ARS) staining

Matrix mineralization was assessed through staining with Alizarin Red S. After stimulation, the cells were washed followed by fixation with paraformaldehyde (4%) for 10 minutes. Cells were then stained with the dye Alizarin Red S (0.2%, pH = 6.8, Solarbio, Beijing, China). Each well was washed 3 times with distilled water to reduce nonspecific binding. Fluorescence signals were visualized using a fluorescence microscope. Then, ARS was distained for quantitative analyses, as previously described[22]. Briefly, cells were incubated with 0.5 mL of 5% cetylpyridinium chloride. The absorbance was then measured at an OD of 405 nm (Thermo Fisher). Final outcomes were plotted relative to control values.

2.8. RT-PCR and real-time PCR

MC3T3-E1 cells were collected for gene expression profiling related to osteogenic differentiation. To perform qRT-PCR, RNA was isolated using TRIzol (Invitrogen). cDNA was produced from 2 μg RNA with reverse transcriptase, as described by the M-MLV manual (New England Biolabs). The primer sequences used for PCR were as follows:

PTX2, forward primer (GCTG GTG CTA GAG GAG CTG) and reverse primer (GGA ATA AAA TAG CTG TTT CAC AAC CT); GAPDH forward primer (GATCGGTACCATCCCAACATCCACAGGTGCTGCT) and reverse primer (GCAAGAGCTTTTAAGATACTTCTCAAG-3). The relative quantity of PTX3 was
normalized to GAPDH. The expression of PTX3 was detected using qPCR with SYBR Green Mix Kits (Applied Biosystems). All results were quantified using the $2^{\Delta\Delta Ct}$ relative quantification method.

2.9. Western blot analysis

Whole-cell lysates were made by lysing MC3T3-E1 cells with RIPA buffer. The samples were subjected to 10% SDS PAGE gel electrophoresis and transferred to a PVDF membrane. The membranes were blocked with blocking solution at room temperature for 2 h on a shaker. Then, PTX3 primary antibody (dilution 1 : 500, Abcam, ab30734, Cambridge, UK), OSX primary antibody (dilution 1 : 1000, Abcam, ab22552, Cambridge, UK), OCN (dilution 1 : 1000, Abcam, ab13420, Cambridge, UK), ALP (dilution 1 : 1000, Abcam, ab83259, Cambridge, UK), RUNX2 (dilution 1 : 1000, Abcam, ab192256, Cambridge, UK), PI3K (dilution 1 : 1000, Cell Signaling Technology, #4249, Cambridge, UK), p-PI3K (dilution 1 : 1000, Cell Signaling Technology, #17366, Shanghai, China), and Akt (dilution 1 : 1000, Cell Signaling Technology, #401 1000, China) and incubated with PDH (dilution 1 1000, AP: 1000, Wuhan: 1000, Wuhan: 1000). Then, the membranes were further probed with HRP-conjugated secondary antibody (Abcam, ab6728). After washing 3 times, the membrane was visualized to determine the activation response using HRP substrates (Thermo Scientific, Rockford, IL, USA).

2.10. Statistical analysis

The results are presented as the means ± S.D. The multiple group differences were assessed by ANOVA using SPSS software (SPSS software, version 19.0, Munich, Germany). P-values < 0.05 were considered to be significant.

3. Results

3.1 PTX3 is induced for osteoblast differentiation

The MC3T3-E1 morphology displayed a spindly fibroblastic shape and was in keeping with previous reports from the literature (Figure 1 A). Next, we monitored the expression profile of PTX3 during osteoblastic differentiation of MC3T3-E1 cells. In our experiment, the cells were fed osteogenic induction medium (OIM) to induce osteoblastic differentiation. Our time-course experiment showed that the mRNA level of PTX3 was gradually induced up to approximately 2.5-, 4-, 6.2- and 8-fold after 3, 7, 14 and 28 d of
induction, respectively (Figure 1 B).

Meanwhile, the Western blot assay confirmed a similar trend of PTX3 over the extended *in vitro* osteogenic induction time (Figure 1 C).

### 3.2 PTX3 promotes osteoblastic differentiation

The responsive induction of PTX3 suggests its potential role in osteoblastic differentiation. We then treated MC3T3-E1 cells with PTX3 lentivirus while they were fed with the osteogenic medium.

Osteogenic induction was observed at 14 d and 28 d following alkaline phosphatase staining and Alizarin Red S staining, respectively. Osteogenically induced MC3T3-E1 cells exhibited nearly 2.5-fold and 3-fold increases in alkaline phosphatase activity and Alizarin Red S compared to noninduced MC3T3-E1 cells. Additionally, ALP activity and Alizarin Red S staining were further enhanced following PTX3 overexpression (P < 0.05, Figure 2 A).

We assessed the expression of four osteoblastic signature genes, including RUNX2, ALP, OCN and OSX. Compared to the control group at day 28, the mRNA expression of RUNX2, ALP, OCN and OSX in the MC3T3-E1 cells growing in OIM plus overexpression PTX3 was several-fold higher than that in the MC3T3-E1 cells maintained in OIM alone (Figure 2 B).

Moreover, the expression patterns of osteoblastic signature proteins, including RUNX2, ALP, OCN and OSX, detected by WB were consistent with those of mRNA expression (Figure 2 C).

### 3.3 Differentially expressed mRNAs in MC3T3-E1 cells treated with PTX3 for 14 d

The mean expression levels of the gene expression profiles are presented in one consistent line after normalization (Figure 3 A). The present study investigated 6 samples, including 3 PTX3 plus OIM-treated samples and 3 OIM-alone samples.

A total of 844 differentially expressed mRNAs, including 498 upregulated and 346 downregulated mRNAs, were identified between OIM and PTX3 plus OIM (Figure 3 B). When we analyzed six MC3T3-E1 cell samples, the 80 top genes clustered into two groups, OIM and OIM plus PTX3, as shown in the heatmap (Figure 3 C).

Differentially expressed gene function (Gene Ontology and KEGG pathway)
enrichment analysis revealed several biological pathways that were significantly affected in the up- and downregulated gene sets. As shown in Figure 3 D, GO analysis revealed that 844 DEGs were significantly enriched in the following biological processes (BP), including response to lipopolysaccharide, positive regulation of inflammatory response, positive regulation of ERK1 and ERK2 cascade, positive regulation of cell proliferation, negative regulation of cell proliferation, mitotic nuclear division, inflammatory response, cell division, cell cycle and angiogenesis. Cellular component (CC) analysis showed proteinaceous extracellular matrix, midbody, membrane, integral component of plasma membrane, extracellular space, extracellular region, extracellular matrix, extracellular exosome, chromosome, centromeric region, and cell surface. In terms of molecular functions (MF), the DEGs were mainly associated with receptor binding, protein homodimerization activity, protein heterodimerization activity, protein binding, hyaluronic acid binding, heparin binding, growth factor activity, cytokine activity, chemokine activity and chemoattractant activity.

The top ten KEGG pathways that had the most significant enrichment terms were Toll-like receptor signaling pathway, TNF signaling pathway, PI3K/Akt signaling pathway, pathway in cancer, HIF-1 signaling pathway, Epstein-Barr virus infection, ECM-receptor interaction, cytokine-cytokine receptor interaction, Chagas disease (American trypanosomiasis) and cell cycle. We selected the PI3K/Akt signaling pathway for experimental verification.

The PPI network of PTX3 and its neighboring genes consisted of 41 nodes and 159 edges (Figure 3 E). There were 28 genes enriched in module 1, 4 genes enriched in module 2 and 3 genes enriched in module 3 when degrees ≥ 5.0 were set as the cutoff criteria.

3.4 PTX3 activates Akt phosphorylation for osteoblastic differentiation

Bioinformatic analysis results found that overexpression of PTX3 mainly activated the PI3K/Akt pathway. Western blot assays suggested that overexpression of PTX3 activated the PI3K/Akt pathway by increasing the phosphorylation of PI3K and Akt (Figure 4 A). OIM leads to activation of PI3K and Akt, and a siRNA of PI3K can partially block this activation (Figure 4 A).
To verify the involvement of the PI3K/Akt pathway in PTX3-mediated osteoblast differentiation, we added the PI3K-specific inhibitor LY294002 in our 14-d differentiation and 28-d experiment. The results showed that MC3T3-E1 cells in the PTX3 and OIM groups had stronger ARS and ALP staining than those in the OIM group alone (Figure 4B). However, this effect was dramatically attenuated when the cells were pretreated with LY294002, as demonstrated by the ~1.1-fold increase (Figure 4B).

As an indication of osteoblast differentiation, the expression of osteoblast-associated markers (RUNX2, ALP, OCN and OSX) was examined using a Western blot assay. Compared with the OIM group, the promotion of the effects of PTX3 on the expression of RUNX2, ALP, OCN and OSX was attenuated by pretreatment with LY294002 (Figure 4C). These results indicate that the PI3K/Akt signaling pathway plays an important role in the effects of PTX3 on the osteogenic differentiation of MC3T3-E1 cells.

4. Discussion

Osteoblasts are bone-building cells, and the fine regulation of osteogenic differentiation is critical to the process of bone formation, modeling, and remodeling. The understanding of signaling pathways involved in osteogenic differentiation may result in the discovery of novel potential targets of osteoporosis. The most common risk factors for osteoporosis include age, menopause-associated hormone changes in women, changes in physical activity, drugs, and other diseases [16,17]. It is widely accepted that age-associated growth hormone, estrogens, and other hormones play a key role in the maintenance of bone homeostasis and the development of osteoporosis [18,19].

PTX3 is induced by many cytokines in immune cells and vascular cells and possesses an immune regulatory function[23]. Moreover, PTX3 dysregulation plays an important roles in cancer development[24] and sepsis[25]. A previous study showed that PTX3 expressed precursor osteoblasts and human osteoblast differentiation but not mature osteoblasts[26]. PTX3 is elevated under inflammatory conditions in bone and plays an important role in bone resorption[26].

In this study, we explored the role of PTX3 in the osteogenic differentiation of MC3T3-E1 cells. Scimeca et al.[27] compared the expression and function of PTX3 by immunohistochemical assay in osteoblasts of osteoporotic, osteoarthritic and young
subjects not affected by any bone disorder. The results showed that PTX3 expression was significantly lower in osteoporosis patients than in osteoarthritic and young subjects, which suggested that PTX3 plays a central role in osteoblast proliferation and differentiation. In this study, we first revealed that the mRNA and protein expression of PTX3 increased with the time of osteogenic differentiation of MC3T3-E1 cells. Our results were different from the study of Lee et al[26], and PTX3 was also more highly expressed in mature osteoblasts. MC3T3-E1 cells are osteoblast progenitor cells that differ from the multidirectional differentiation potential of stem cells. Then, overexpression of PTX3 by transfection with expression plasmids caused more ALP activity and deposition of calcium salts in the early and late stages, respectively. In particular, both Scimeca’s[28] and Grčević’s[12] groups demonstrated that PTX3 is involved in the deposition of bone matrix.

Further work is necessary to identify the downstream genes of PTX3 and the mechanism of action governing this pathway. Gene chip methods employed samples collected from osteogenic differentiation of MC3T3-E1 cells with or without overexpression of PTX3. A total of 844 DEGs were identified and mainly function in cell proliferation and extracellular space. We further observed strong enrichment of the PI3K/Akt membrane in KEGG enrichment analysis, which was further verified by clinical experiments. It was inferred that the overexpression of PTX3 was associated with a clear increase in the phosphorylation of PI3K and Akt.

The PI3K/Akt signaling pathway plays important roles in the osteogenic differentiation of MC3T3-E1 cells[29]. To further verify whether the promotion effects of PTX3 occurred via Akt, we employed the PI3K inhibitor LY294002. LY294002 abolished the elevated ALP activity and calcium deposition induced by the overexpression of PTX3 when added to MC3T3-E1 cells. Moreover, the inhibition of LY294002 was further confirmed by Western blot analysis for osteoblastic markers. Consistent with our study’s findings, Chang et al.[13] revealed that PTX3 primarily influences the PI3K/Akt signaling pathway in head and neck cancer cell metastasis. Another recent study showed that PTX3 modulated the high-density lipoprotein-induced inflammatory response through the PI3K/Akt signaling pathway[30].

Our study indicates that PTX3 plays important roles in the regulation of osteogenic
differentiation of MC3T3-E1 cells. We propose that the activation of PI3K/Akt signaling is a potential mechanism through which PTX3 alters bone metabolism. Further characterization of this newly identified PTX3 for other potential ways and future study using animal models will shed light on its potential therapeutic implications for osteoporosis.

Figure legends

Figure 1 Time-dependent increase in PTX3 osteogenic induction. A Cell morphology of MC3T3-E1 osteoblasts cultivated in culture flasks for 24 h (Scale bar = 100 μm). B The gene expression of PTX3 was assessed by quantitative real-time PCR after osteogenic induction for 1, 3, 7, 14 and 28 d. C Western blotting and quantitative analysis using the Western blot assay showed that PTX3 revealed a time-dependent increase in the gray level of osteogenic induction for 1, 3, 7, 14 and 28 d. *P<0.05.

Figure 2 Overexpression of PTX3 promotes osteoblastic differentiation. A, ALP staining intensity and Alizarin Red S staining were enhanced in the PTX3 overexpression group compared with the control group and OIM alone group for 14 d and 28 d in the presence or absence of OIM. Cells were cultured with osteogenic induction medium (OIM) with or without PTX3 for 14 d. Gene levels (B) and protein levels (C) of RUNX2, ALP, OCN and OSX (* P < 0.05).

Figure 3 Bioinformatic analysis of the differentially expressed mRNAs in MC3T3-E1 cells treated with PTX3 for 14 d. A Box plots of gene expression data before and after normalization. B Volcano plot of the differentially expressed genes; (red) upregulated expressed genes; (green) downregulated genes; and (black) nondifferentially expressed genes. C Heatmap of the top 80 differentially expressed genes (color scheme reflects logarithmic gene expression of each group; highest in red and lowest in blue). D The results of the gene ontology (GO) and KEGG pathway enrichment analyses of the DEGs. BP biological process, CC cellular component, MF molecular function, KEGG Kyoto Encyclopedia of Genes and Genomes, GO Gene Ontology.

E PPI network, three MCODE models were applied to this network to identify neighborhoods where proteins were densely connected. Three significant modules with a score>5.0 were selected. Module 1, MCODE score=6.4, Module 2, MCODE score=5.2 and Module 1, MCODE score=5.1. PPI, protein-protein interaction; DEGs, differentially
expressed genes.

Figure 4 PTX3 participates in the PI3K/AKT signaling pathway. A Western blotting was performed to assess the activation of the PI3K/AKT signaling pathway by detecting PI3K, p-PI3K, AKT and p-AKT in MC33-E1 cells. B Representative images of ALP staining after 14 d of culture and ARS after 28 d of OIM culture with or without LY294002. C The PI3K-Akt pathway mediated the elevated effect of PTX3 overexpression during the osteogenic differentiation of MC3T3-E1 cells. MC3T3-E1 cells were incubated with LY294002 for 2 h prior to treatment with PTX3. RUNX2, ALP, OCN and OSX protein expression and quantitative analysis were measured. ALP, alkaline phosphatase; ARS, Alizarin Red S; OIM, osteogenic differentiation medium. (*P < 0.05).
### A

|       | Control | OIM   | OIM+PTX3 | OIM+si-PTX3 |
|-------|---------|-------|----------|-------------|
| si-PTX3 | - - - + |       |          |             |
| OIM    | - + + + |       |          |             |
| PTX3   | - + + + |       |          |             |
| PI3K   | - - + - |       |          |             |
| p-PI3K | - + - - |       |          |             |
| Akt    | - - + - |       |          |             |
