LETTER

A Note on Two Constructions of Zero-Difference Balanced Functions*

Zongxiang Yi\textsuperscript{a}, Member, Yuyin YU\textsuperscript{b}, Chunming TANG\textsuperscript{c}, and Yanbin ZHENG\textsuperscript{d}, Nonmembers

SUMMARY Notes on two constructions of zero-difference balanced (ZDB) functions are made in this letter. Then ZDB functions over \( \mathbb{Z}_n \times \prod_{i=0}^{k} \mathbb{F}_q \) are obtained. And it shows that all the known ZDB functions using cyclotomic cosets over \( \mathbb{Z}_n \) are special cases of a generic construction. Moreover, applications of these ZDB functions are presented.

\textbf{key words:} constant composition code, constant weight code, difference system of sets, frequency-hopping sequence, zero-difference balanced function

1. Introduction

Let \((A, +)\) and \((B, +)\) be two finite abelian groups. A function \(f\) from \(A\) to \(B\) is called an \((n, m, \lambda)\) zero-difference balanced (ZDB) function if there is a constant number \(\lambda\), such that
\[\{x \in A \mid f(x+a) - f(x) = 0\}\] for every element \(a \in A \setminus \{0\}\), where \(n = |A|\), \(m = |\text{Im}(f)|\), and \(|\text{Im}(f)|\) is the image set of \(f\).

In 2008, Ding first proposed the concept of ZDB function and showed that optimal constant composition codes (CCC) can be obtained from ZDB functions \([1]\). Later, Ding\([2]\), Zhou et al.\([3]\) and Wang and Zhou\([4]\) showed that optimal perfect difference systems of sets (DSS), optimal constant weight codes (CWC) and optimal frequency-hopping sequences (FHS) can be obtained from ZDB functions, respectively. Since CCC, CWC, DSS and FHS have many applications in combination designs and communication systems, many researchers have been working on constructing more ZDB functions (see \([1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]\) and the references therein).

In this letter, we concern those ZDB functions constructed by generalized cyclotomic cosets. Some authors \([7, 8]\) studied the construction of ZDB functions on the rings \(\mathbb{Z}_n\). They showed that there exist non-trivial ZDB functions on \(\mathbb{Z}_n\) only for odd integers \(n\). Ding et al. \([7]\) constructed a class of ZDB functions for any positive integer \(n\) by using the product of finite fields. In 2017, Yi et al. generalized the construction from the residue rings \(\mathbb{Z}_n\) and finite fields \(\mathbb{F}_q\) to generic rings \([12]\).

The main contribution of the letter are twofold. Firstly, by generalizing the construction of ZDB functions proposed by Cai et al. \([10]\), ZDB functions can be obtained over \(\mathbb{Z}_n \times \prod_{i=0}^{k} \mathbb{F}_q\). Secondly, it shows that all the known ZDB functions using cyclotomic cosets over \(\mathbb{Z}_n\) \([6, 7, 8]\), are indeed special cases of the generic construction in \([12]\).

This letter is organized as follows: In Section 2, the construction in \([12]\) is recalled, and then notes on two constructions of ZDB functions are made. Applications of ZDB functions are presented in Section 3. Section 4 concludes this letter.

2. Two constructions of ZDB Functions

2.1 Notations

Unless otherwise stated, \((R, +, \times)\) is always a commutative ring with identity. Let \(R^*\) denote the set of all invertible elements in \((R, \times)\). Let \(R^+\) denote the set of all nonzero elements in \(R\). Define \(x/y = x \times y^{-1}\), for \(x \in R, y \in R^*\).

For any subset \(A\) of \(R\) and any element \(a\) of \(R\), define
\[a + A = \{a + x \mid x \in A\}, A + a = a + A\]
\[aA = \{ax \mid x \in A\}, Aa = \{xa \mid x \in A\}\]

Moreover, the set of all natural numbers is denoted by \(\mathbb{N}\). The set of all integers is denoted by \(\mathbb{Z}\). The set of all positive integers is denoted by \(\mathbb{Z}^+\). A finite field with \(q\) elements is denoted by \(\mathbb{F}_q\).

2.2 The Method of Yi

In this subsection, we will recall the method of Yi \([12]\).

**Proposition 1**\([12]\). Let \((R, +, \times)\) be a ring of order \(n\), and let \(G\) be a subgroup of \((R, \times)\). Suppose \(|G| = e\). Define \(S = \{\alpha G \mid \alpha \in R\}\). If \(G\) satisfies the condition
\[\{G - 1\} \setminus \{0\} \subseteq R^*\]

then
1. $S$ is a partition of $R$;
2. $|aG| = e$, for every $a \in R^*$;
3. $|S| = \frac{n-1}{e-1} + 1$;
4. For every $a \in R^*$,
   \[ \{x \in R \mid f(x + a) = f(x)\} = \{a(g-1)^{-1} \mid g \in G \setminus \{1\}\}. \]
5. $f = f_2(f_1(x))$ is an $(n, \frac{n-1}{e-1} + 1, e-1)$ ZDB function from $(R, +)$ to $(\mathbb{Z}_{\frac{n-1}{e-1} + 1}, +)$, where $f_1(x)$ is the map from $R$ to $S$ which maps an element $x$ into $aG$ such that $x \in aG$, and $f_2(x)$ is an arbitrary bijective map from $S$ to $\mathbb{Z}_{\frac{n-1}{e-1} + 1}$.

In Proposition 1, a set of coset representatives of $S$, denoted by $L_G$, can be obtained by randomly selecting one element in $aG \in S$. Note that $0G = \{0\} \in S$ and $0 \in L_G$. Let $S^* = S \setminus \{0\}$. Similarly, a set of coset representatives of $S^*$, denoted by $L_{G^*}$, can be obtained too, namely, $L_{G^*} = L_G \setminus \{0\}$.

2.3 One construction of ZDB functions

In this subsection, we will propose one construction of ZDB functions. With the notations in Subsection 2.2, two indicators are defined. For any $r \in R^*$, there exists a unique element $x \in L_{G^*}$ such that $r = aG$. Furthermore, there exists a unique element $g \in G$ such that $r = ag$.

Now the row indicator $RI_{L_{G^*}}$ and the column indicator $CI_{L_{G^*}}$ are defined as follows:

- $RI_{L_{G^*}} : R^* \to L_{G^*}$, $CI_{L_{G^*}} : R^* \to G$,
- $r \mapsto a_r$, $r \mapsto g_r$.

The column indicator has the following property.

**Lemma 1.** Let $(R, +, x)$ be a ring. Let $R$ be a subgroup of $(R, x)$, such that $(G - 1) \setminus \{0\} \subset R^x$. Suppose $e = |G|$. Let $a(g)$ be a function from $G$ to $R^*$, such that $RI_{L_{G^*}}(a(g)) = RI_{L_{G^*}}(a(g))$ for every $g \in G$. Then

\[ \{CI_{L_{G^*}}(a(g))/CI_{L_{G^*}}(a(g)) \mid g \in G\} = G. \]

Moreover, $CI_{L_{G^*}}(a(g))/CI_{L_{G^*}}(a(g)) = 1$ if and only if $g = 1$.

**Proof.** Suppose $RI_{L_{G^*}}(a(g)) = \alpha$. Let $a(g) = ag'$, where $g' \in G$. Then $a(g)g = ag'g$. We have

\[ CI_{L_{G^*}}(a(g))/CI_{L_{G^*}}(a(g)) = g'/g'. \]

When $g$ runs over $G$, $g'/g'$ run over $G$ too. Moreover, if $g'/g'$ is defined, then $g = g'$ only if $g = 1$. Hence $CI_{L_{G^*}}(a(g))/CI_{L_{G^*}}(a(g)) = 1$ if and only if $g = 1$. \(\square\)

Now we give our construction as Theorem 1.

**Theorem 1.** Let $(R, +)$ be a ring of order $n$, and let $G, H$ be two subgroups of $(R, x)$. Suppose the following conditions hold:

1. $(G - 1) \setminus \{0\} \subset R^x$;
2. $(H - 1) \setminus \{0\} \subset R^x$;
3. $|H| = |G| - 1$.

Then there exist $(n, \frac{n-1}{e-1} + 1, e - 2)$ ZDB functions from $(R, +) \times (G, x)$ to $(\mathbb{Z}_{\frac{n-1}{e-1} + 1}, +)$, where $e = |G|$.

**Proof.** Let $0$ and $1$ denote the identities of $(R, +)$ and $(R, x)$, respectively. Define $T = \{0, (0, 1)\} \cup L_{H^*}^* \cup L_{G^*}^* \times G$. (2)

Followed from Proposition 1, we have $|L_{H^*}^*| = \frac{n-1}{e-1}$, $|L_{G^*}^*| = \frac{n-1}{e-1}$, and $\frac{|T|}{|R|} = \frac{|L_{H^*}^*| + L_{G^*}^*|2 + 2}{\frac{n-1}{e-1} + 1}$. Denote $R = (R, +) \times (G, x)$. Now we define a function from $\overline{R}$ to $T$:

\[ f_1(r, x) = \begin{cases} 0, & \text{if } r = 0 \text{ and } x = 1, \\ \frac{RI_{H^*}}(r), & \text{if } r = 0 \text{ and } x \neq 1, \\ \frac{RI_{G^*}}(r), & \text{if } r \neq 0 \text{ and } x = 1, \\ \frac{RI_{G^*}(r), xCI_{G^*}}(r), & \text{if } r \neq 0 \text{ and } x \neq 1. \end{cases} \]

Let $f_2(x)$ be an arbitrary bijective map from $T$ to $\mathbb{Z}_{\frac{n-1}{e-1} + 1}$. We assert that $f = f_2(f_1(x))$ is an $(en, \frac{n-1}{e-1} + 1, e - 2)$ ZDB function from $\overline{R}$ to $\mathbb{Z}_{\frac{n-1}{e-1} + 1}$, $+$.

Obviously, for any $\Delta = (\Delta_r, \Delta_x) \neq (0, 1)$, we have

\[ \{y \in \overline{R} \mid f(y + \Delta) - f(y) = 0\} = \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\}. \]

In the following, we will show that

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\}. \]

Firstly, we make a partition of $\overline{R}$. Let

\[ \overline{R} = \bigcup_{i=1}^{4} R_i, \]

where

\[ R_1 = \{r, x\} \in \overline{R} \mid r = 0, x = 1\}, R_2 = \{r, x\} \in \overline{R} \mid r = 0, x \neq 1\}, \\ R_3 = \{r, x\} \in \overline{R} \mid r \neq 0, x = 1\}, R_4 = \{r, x\} \in \overline{R} \mid r \neq 0, x \neq 1\}. \]

Note that if $f_1(y + \Delta) = f_1(y)$, then $y + \Delta$ and $y$ must belong to some $R_i$ where $1 \leq i \leq 4$.

Secondly, we have a discussion over $(\Delta_r, \Delta_x) \neq (0, 1)$. 1.

1.1. If $(r, x) \in R_1$, then $\Delta_r, \Delta_x \neq 0$. So

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{0\}. \]

1.2. If $(r, x) \in R_2$, then $\Delta_r, x \neq 0$. So

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{0\}. \]

1.3. If $(r, x) \in R_3$, then

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{0\}. \]

2. Case $\Delta_r \neq 0$ and $\Delta_x = 1$:

2.1. If $(r, x) \in R_1$, then $\Delta_r \neq 0$ and $\Delta_x = 1$. So

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{0\}. \]

2.2. If $(r, x) \in R_2$, then $\Delta_r \neq 0$ and $\Delta_x = 1$. So

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{0\}. \]

2.3. If $(r, x) \in R_3$, then $\Delta_r \neq 0$ and $\Delta_x = 1$. So

\[ \{y \in \overline{R} \mid f_1(y + \Delta) = f_1(y)\} = \{0\}. \]
and any cyclic group is isomorphic to 2

(1) on \( \mathbb{Z}^n \times \mathbb{Z}_{e+1}^+ \) such that

\[
\begin{align*}
(3.2. If & \quad e(n_1, n_2, \ldots, n_k), then \quad \exists \quad (e, \frac{m+1}{e}, e-2) \text{ ZDB functions from } (\mathbb{Z}_{e+1}, \times) \text{ to } (\mathbb{Z}_{e+1}, \times),
\end{align*}
\]

Remark 3. [7] showed how to construct subgroups satisfying the Condition (1) on \( F_{p_i}^n \). Then ZDB functions can be obtained by Corollary 2. For example, let \( n = 25 \) and \( e = 4 \), we obtain a \((100, 34, 2)\) ZDB function from \( \mathbb{F}_{25} \times \mathbb{Z}_4 \) to \( \mathbb{Z}_{34} \). Moreover, let \( n = 121 \) and \( e = 4 \), we obtain a \((726, 146, 4)\) ZDB function by Corollary 2. This ZDB function cannot be retrieved by the constructions in [7, 8, 10]. But it may be retrieved by the construction in [12], if an appropriate ring is given.

To show that Theorem 1 can generate many more ZDB functions over different rings, we consider the matrix ring \( M \). Denote \( A = (\begin{array}{cc} 3 & 0 \\ 0 & 3 \end{array}) \) and \( B = (\begin{array}{cc} 4 & 4 \\ 1 & 0 \end{array}) \). It is easy to check that both \( G = (A) \) and \( H = (B) \) satisfy the conditions in Proposition 1, and that \(|G| = 4, |H| = |G| - 1 = 3\). Hence there exists a \((2500, 834, 2)\) ZDB function over \( M \) by Theorem 1. It is the first ZDB function proposed over matrix rings and noncommunicative rings.

2.4 The other construction of ZDB functions

In this subsection, we will construct the second construction of ZDB functions. With the notations in Subsection 2.2, we have

**Proposition 2.** Let \((R, +, \times)\) be a ring of order \( n \geq 3 \), and let \( G \) be a subgroup of \((R, \times)\). If \( G \) satisfies the following conditions:

1. \(|G - \{0\}| \subseteq R^e;\)
2. \(|G + \{1\}| \subseteq R^n\),

then there exist \((n, \frac{n-1}{2e} + 1, 2e - 1)\) ZDB functions, where \( e = |G| \).

**Proof.** Let \(-G = -1 \times G\) and \( H = G \cup (-G) \) be a subgroup of \((R, \times)\). It is easy to verify that \(|H| = 2e\) and \((H - 1) \\{0\} \subseteq R^n\). Then the proof is completed by Proposition 1.

Remark 4. The proof indicates that Proposition 2 is a special case of Proposition 1 since the constructed subset \( H \) is a subgroup satisfying Condition (1). So the special cases of Proposition 2 are indeed special cases of Proposition 1.

Finally, we will illustrate that the ZDB functions in [6, 7, 8] are indeed special cases of the generic construction in [12].

1. Let \( R = \mathbb{Z}_n \) and \( G = \langle b \rangle \), where \( b \) be an element constructed by Lemma 3 in [8]. Then Theorem 1 in [6]
and Theorem 1 in [8] can be obtained by Proposition 1.

2. Let \( R = \prod_{i=1}^{k} \mathbb{F}_{q_i} \), where \( n = \prod_{i=0}^{k} q_i \) and \( q_i \) are prime powers \((i = 1, 2, \ldots, k)\). Let \( G = \langle b \rangle \), where \( b = \langle b_1, b_2, \ldots, b_k \rangle \) and \( b_1 \) is an element in \( \mathbb{F}_{q_1} \) of order \( e \) \((i = 1, 2, \ldots, k)\). Obviously we have \( e \mid q_i - 1 \) for \( i = 1, 2, \ldots, k \). Then Theorem 1 in [7] can be obtained by Proposition 1.

3. Let \( R = \mathbb{Z}_{2m-1} \) and \( G = \langle 2 \rangle \), where \( m \) is an odd prime number. It is easy to verify that \( G \) satisfies Condition (1) in Proposition 1 and \( |G| = m \). So Theorem 3 in [7] can be obtained by Proposition 1.

4. Let \( R = \mathbb{Z}_{2m-1} \) and \( G = \langle 2 \rangle \), where \( m \) is an odd prime number. It is easy to verify that \( G \) satisfies all the conditions in Proposition 2 and \( |G| = m \). So Theorem 5 in [7] can be obtained by Proposition 2.

5. Let \( s \) be a prime, \( b \geq 2 \), and \( \gcd(s, b - 1) = 1 \). Let \( R = \mathbb{Z}_{ps-1} \) and \( G = \langle e \rangle \). It is easy to verify that \( G \) satisfies Condition (1) in Proposition 1 and \( |G| = s \). So Corollary 1 in [8] can be obtained by Proposition 1.

6. Let \( s \) be an odd prime, \( b \geq 2 \), and \( \gcd(s, b - 1) = 1 \). Let \( R = \mathbb{Z}_{ps-1} \) and \( G = \langle e \rangle \). It is easy to verify that \( G \) satisfies all the conditions in Proposition 2 and \( |G| = s \). So Corollary 2 in [8] can be obtained by Proposition 2.

7. Let \( s \) be a prime, \( b \geq 2 \), and \( \gcd(s, b - 1) = 1 \). Suppose \( p = \frac{b - 1}{s} \) is an odd prime. Let \( R = \mathbb{Z}_{ps-1} \) and \( G = \langle e \rangle \). Note that \( \mathbb{Z}_{ps-1} \neq \mathbb{Z}_{ps} \). It is easy to verify that \( G \) satisfies Condition (1) in Proposition 1 and \( |G| = s \). So Theorem 2 in [8] can be obtained by Proposition 1.

3. Applications

The ZDB functions in Proposition 2 have the same structure as those in [12], and they have no new parameters. So only the applications of ZDB functions in Theorem 1 are presented in this section. It is necessary to show the following property of our ZDB functions before introducing the applications.

**Proposition 3.** Let \( f : A \rightarrow B \) be an \((en, \frac{en-1}{e-1} + 1, e - 2)\) ZDB function constructed by Theorem 1, and let \( m = \frac{en-1}{e-1} \).

Denote \( w_b = |\{ x \in A \mid f(x) = i \}| \) for every \( b \in B \). Then for the multi-set, we have

\[
\{ w_b \mid b \in B \} = \{ 1, e - 1, e - 1, \ldots, e - 1 \}.
\]

3.1 Optimal Constant Composition Codes

An \((n, M, d, \{ w_0, w_1, \ldots, w_{q-1} \})_q \) constant composition code (CCC) is a code over an abelian group \( \{ b_0, b_1, \ldots, b_{q-1} \} \) with length \( n \), size \( M \) and minimum Hamming distance \( d \), such that in every codeword the element \( b_i \) appears exactly \( w_i \) times for every \( i \) \((0 \leq i \leq q - 1)\). Let \( A_q(n, d, \{ w_0, w_1, \ldots, w_{q-1} \}) \) denote the maximum size of an \((n, M, d, \{ w_0, w_1, \ldots, w_{q-1} \})_q \) CCC. A CCC is optimal if the bound in Lemma 2 is met.

**Lemma 2.** [13] If

\[
nd - n^2 + \sum_{i=0}^{q-1} w_i^2 > 0,
\]

then

\[
A_q(n, d, \{ w_0, w_1, \ldots, w_{q-1} \}) \leq \frac{nd \text{ nd} - n^2 + \sum_{i=0}^{q-1} w_i^2}{2}.
\]

Using the framework in [11], new optimal CCCs can be constructed from ZDB functions.

**Theorem 2.** Let \( f \) be an \((en, \frac{en-1}{e-1} + 1, e - 2)\) ZDB function constructed by Theorem 1. Then there exists an optimal \((en, en - e + 2, \{ 1, e - 1, e - 1, \ldots, e - 1 \})_{\frac{en-1}{e-1} + 1} \) CCC.

To compare the parameters of some known optimal CCCs, the reader is referred to Table II in [10].

3.2 Optimal Constant Weight Codes

An \((n, M, d, w)_q \) constant weight code (CWC) is a code over an abelian group \( \{ b_0, b_1, \ldots, b_{q-1} \} \) with length \( n \), size \( M \) and minimum Hamming distance \( d \), such that the Hamming weight of each codeword is \( w \). Let \( A_q(n, d, w) \) denote the maximum size of an \((n, M, d, w)_q \) CWC. A CWC is optimal if the bound in Lemma 3 is met.

**Lemma 3.** [14] If \( nd - 2nw + \frac{w^2}{1-e} > 0 \), then

\[
A_q(n, d, w) \leq \frac{nd}{nd - 2nw + \frac{w^2}{1-e}}.
\]

The codes constructed from ZDB functions in Theorem 2 are CWCs. Zhou et al. and Yi et al. gave specific constructions in [3] and [12], respectively. With the framework established by [12], the ZDB functions constructed in Theorem 1 can generate optimal CWCs.

**Theorem 3.** With the notations in Theorem 1, let \( f = f_2(f_1(x)) \) be an \((en, \frac{en-1}{e-1} + 1, e - 2)\) ZDB function such that \( f_2 \) maps \( 0 \) to \( 0 \). Then there exists an optimal \((en, en - e + 2, \{ 1, e - 1, e - 1, \ldots, e - 1 \})_{\frac{en-1}{e-1} + 1} \) CWC.

**Remark 5.** Note that \( f_2(x) \) is a bijective map from \( T \) (defined in (2)) to \( \mathbb{Z}_{\frac{en-1}{e-1} + 1} \). There are many such bijective maps mapping \( 0 \) to \( 0 \).

3.3 Optimal and Perfect Difference Systems of Sets

Difference systems of sets (DSS) are related with comma-free codes, authentication codes and secrete sharing schemes [15, 16]. Let \( \{ D_0, D_1, \ldots, D_{q-1} \} \) be disjoint subsets of an abelian group \( (G, +) \). Denote \( |G| = n \) and \( |D_i| = w_i \) for every \( i \). Then \( \{ D_0, D_1, \ldots, D_{q-1} \} \) is said to be an \((n, \{ w_0, w_1, \ldots, w_{q-1} \}, \lambda) \) DSS if the multi-set

\[
\{ x - y \mid x \in D_i, y \in D_j, 0 \leq i \neq j \leq q - 1 \}
\]

contains every non-zero element \( g \in G \) at least \( \lambda \) times. Moreover, a DSS is perfect if every non-zero element \( g \) appears exactly \( \lambda \) times in the multi-set just mentioned above. It is required that
as small as possible. A DSS is called optimal if the bound in Lemma 4 is met.

**Lemma 4.** [17] For an \((n, [w_0, w_1, \ldots, w_{q-1}], \lambda)\) DSS, we have

\[
\tau_q(n, \lambda) \geq \sqrt{\text{SQUARE}(\lambda(n-1) + \lceil \frac{\lambda(n-1)}{q-1} \rceil)},
\]

where SQUARE\((x)\) denotes the smallest square number that is no less than \(x\) and \(\lceil x \rceil\) denotes the smallest integer that no less than \(x\).

Using the framework in [2], we obtain optimal DSSs in Theorem 4.

**Theorem 4.** Let \(f\) be an \((en, \frac{en-1}{e-1} + 1, e-2)\) ZDB function constructed by Theorem 1. Then there exists an optimal \((en, \{1, e-1, \ldots, e-1\}, en - e + 2)\) perfect DSS.

**Remark 6.** DSSs on non-cyclic groups are related to authentication codes and secret sharing schemes [15, 16].

The optimal DSSs constructed in this paper are partitioned-type. To compare the parameters of some known partitioned-type optimal DSSs, the reader is referred to Table III in [10].

4. Conclusion

In this letter, we generalized the construction of ZDB functions in [10]. It may instantiate ZDB functions with new parameters if Condition (1) is studied over other rings. Moreover examples of ZDB functions over noncommunicative ring are first given. Finally we point out that some known ZDB functions are indeed special cases of the generic construction in [12].
