We study how charges of global symmetries that are manifest in the ultra-violet definition of a theory are realized as topological charges in its infra-red effective theory for two-dimensional theories with $\mathcal{N} = (2, 2)$ supersymmetry. We focus on the charges that the states living on $S^1$ carry. The central charge—or BPS masses—of the supersymmetry algebra play a crucial role in making this correspondence precise. We study two examples: $U(1)$ gauge theories with chiral matter, and world-volume theories of “dynamical surface operators” of 4d $\mathcal{N} = 2$ gauge theories. In the former example, we show that the flavor charges of the theory are realized as topological winding numbers in the effective theory on the Coulomb branch. In the latter, we show that there is a one-to-one correspondence between topological charges of the effective theory of the dynamical surface operator and the electric, magnetic, and flavor charges of the 4d gauge theory. We also examine the topologically charged massive BPS states on $S^1$ and discover that the massive BPS spectrum is sensitive to the radius of the circle in the simplest theory—the free theory of a periodic twisted chiral field. We clarify this behavior by showing that the massive BPS spectrum on $S^1$, unlike the BPS ground states, cannot be identified as elements of a cohomology.

I. INTRODUCTION

Let us consider a quantum field theory defined at some ultra-violet (UV) scale with a set of massive fields of mass $\sim \mu$, which we schematically denote $\{\phi_i\}$. In the infra-red (IR) effective theory, describing the physics far below the mass scale $\mu$, the fields $\{\phi_i\}$ are integrated out and are absent from the path-integral description of the IR field theory, if there is one. Given that the UV Lagrangian had some global symmetry, a natural question to ask is how to detect the symmetries of the UV theory in the IR effective theory. There are well understood classic examples where the charge of a global symmetry of the UV theory manifests itself as a topological charge in the IR [1–8]. In this paper, we study some two-dimensional examples of theories with $\mathcal{N} = (2, 2)$ supersymmetry in which the correspondence between the charges of the global symmetries in the UV and the topological charges in the IR can be made precise.

The crucial fact that enables us to match the UV and IR charges, is that the BPS central charge of a state in a 2d $\mathcal{N} = (2, 2)$ theory is determined by its topological charges [9]. We focus on examples with theories with one twisted chiral multiplet, but our results are expected to generalize to other cases. These topological charges arise when the twisted superpotential of the theory is multi-valued with respect to the value of the scalar $\sigma$ in the twisted chiral multiplet [10, 11]. The multi-valuedness of the superpotential gives rise to a non-trivial topological structure of the space “$X$” the twisted chiral field $\sigma$ takes values in—in particular, the homology group $H_1(X)$ can be non-trivial. In this case, the states living on the spatial slice $S^1$, or “$S^1$ states,” can carry topological charges valued in $H_1(X)$. The supersymmetry algebra acting on states with a given topological charge has a central term determined by the topological charge [10, 11]. This central charge gives a BPS bound to the mass of states [9, 12]. When a given theory is an IR effective theory of some UV theory, the topological charges in the IR can be matched with global charges in the UV by comparing the central charge of the supersymmetry algebra of the “two” theories.

The topologically charged BPS states, whose mass saturates the lower bound given by a non-zero central charge of the supersymmetry algebra, come in shortened multiplets of the supersymmetry algebra. There is much to be learned about the massive BPS states on $S^1$, whose spectrum is expected to be more subtle compared to BPS ground states. For example, it has been demonstrated in [11] that classical BPS field configurations carrying topological charge do not necessarily survive as BPS states in the quantum theory. In this paper, we show that the massive BPS spectrum depends on the radius of the spatial circle by examining the simplest theory with non-trivial topological sectors—the theory of a free periodic twisted chiral field with a linear twisted superpotential. For generic values of the radius, there are no massive BPS states on $S^1$ in the free theory, while BPS states do appear for discrete values.

In the Morse theory-based approach to BPS spectra [13–16], the BPS ground states of a sigma model can be identified as the elements of a particular cohomology of the loop space $\mathcal{L}X$ of the target space $X$. This point of view, one might be wary about the claim that the BPS spectra of a theory exhibits unstable behavior under the variation of information contained in the (twisted) su-

* dpark at sgp.stonybrook.edu

1 This approach is also implicit in the work [17].
perpotential of the theory. We clarify this point by showing that massive BPS states in topological sectors are not elements of a cohomology represented by harmonic forms, but rather distinguished differential forms on loop space that are annihilated by a certain quadratic operator. In the process, we find that the supersymmetry charges can be identified with operators acting on differential forms of $\mathcal{L}X$. Let us note that the loop space $\mathcal{L}X$ consists of disjoint components that correspond to different topological sectors of the theory. In topologically non-trivial sectors in which the central charge of the supersymmetry algebra does not vanish, the supersymmetry charges can be constructed by adding a connection to the equivariant differential operators that have been studied, among other places, in [13, 18, 19].

We have taken only very preliminary steps in studying massive BPS states on $S^1$ in this paper. It would be interesting to understand what we can learn about them, and to further develop and utilize computational tools [13–17, 20–22] that give access to information about these states.

This paper is organized as follows. In the first two sections, we study examples of theories whose superpotential in the IR is multi-valued in the target space. The first example, which we study in section II, is the Coulomb branch effective theory of a $U(1)$ gauge theory with $n$ charged chiral matter fields. We show that the topological charges of the $S^1$ states of the effective theory is given by ($n-1$) winding numbers, and identify them with flavor charges in the UV. In section III, we study what we call the “dynamical surface operator theory” of 4d $\mathcal{N} = 2$ gauge theories [23–27]. This theory is obtained by taking the surface operator theory of [28], and promoting the complex Fayet-Iliopoulos (FI) parameter to a dynamical twisted chiral multiplet. We show that the topological charges of this theory coincides with the electric, magnetic and flavor charges of the four-dimensional theory. We end by studying the behavior of the BPS spectrum of $S^1$ states in section IV. We first study the spectrum of the theory of a single periodic twisted chiral field with a linear potential in some detail and show that its spectrum varies as the radius of the spatial circle is changed. We then study the problem by recognizing that the states of the theory are differential forms on the loop space of a flat cylinder and characterize the BPS states in this language. In particular, we construct the supersymmetry operators modifying equivariant differential operators by adding a connection. Some technical details are presented in the appendix.

Note added: During the completion of this paper, I have become aware that its contents have some overlap with the work [16]. I would like to thank the authors of [16] for kindly sharing relevant parts of their manuscript before its publication.

II. FIRST EXAMPLE: $U(1)$ GAUGE THEORY

Our first and main example is a 2d $\mathcal{N} = (2, 2)$ gauge theory with a $U(1)$ gauge group and $n$ chiral multiplets $\Phi_k$ of charge $q_k$. We turn on generic twisted masses $m_k$ for the chiral fields, and a complex FI term with parameter $t$. Our conventions are such that the imaginary part of the complex FI parameter is the theta angle of the theory. Such theories were studied in great detail in [29, 30]. The UV theory has a $U(1)^{n-1}$ flavor symmetry, whose charges we denote by $Q_i$. We denote the gauge charge $Q_0$. The flavor symmetry $U(1)_i$ is defined so that the chiral multiplet $\Phi_k$ has charge $\alpha_{i,k}$. The $\alpha_{i,k}$ are chosen to satisfy $\alpha_{i,k}q_k = 0$, so that they are orthogonal to the gauge charge. Here, let us introduce the unique matrix $\delta_{i,k}$ such that

$$q_k\delta_{k,i} = 0 \quad \text{and} \quad \beta_{k,i}\alpha_{i} = \delta_{k,i} - q_kq_i/q_i^2. \quad (1)$$

While $\alpha_{i,k}$ is an $(n-1) \times n$ matrix, it is useful to think of it as an invertible linear map from the $(n-1)$-dimensional subspace $S_F = \{ (x_k) : q_kx_k = 0 \}$ of $\mathbb{R}^n$ to $\mathbb{R}^{n-1}$. $\beta$ is the inverse map of $\alpha$ from $\mathbb{R}^{n-1}$ to $S_F$.

The $U(1)$ gauge multiplet has a complex scalar field $\sigma$ as a component. At some IR scale $\mu_{IR} \ll m_k$, the chiral fields can be integrated out from the theory. The effective theory in the IR is a theory with a single $U(1)$ vector multiplet with a twisted superpotential [29]:

$$2\pi \bar{W} = -t_{eff}\Sigma - \sum_k (q_k\Sigma + m_k) \log(q_k\Sigma + m_k)/\mu_{IR}, \quad (2)$$

where we have dropped a constant shift, which does not affect the physics in anyway. The field $\Sigma$ is the twisted superfield that has $\sigma$ as its lowest component. The charges $Q_i$ are then identified with the topological charges of the effective theory:

$$Q_i = \frac{1}{2\pi} \int_L dx \partial_x \sum_k \alpha_{i,k} \arg(q_k\sigma + m_k) \quad (3)$$

where the integral is taken over the spatial slice $L$ of the QFT. This equation can be obtained by integrating expectation value of the flavor current component $\gamma^\mu j_k^\mu$.

In particular, it can be understood as coming from the term $\bar{\psi}_k\gamma^0\psi_k$ in $j_k^0$. Due to the fact that $(q_k\sigma + m_k)$ is the effective complex twisted mass of the fermions in the chiral multiplet $\Phi_k$[7]. Here, $\psi_k$ is the Dirac fermion in the multiplet $\Phi_k$. We prove this claim when $L$ is an $S^1$ with more rigor shortly.

Before doing so, let us note that when $L$ is a circle, $Q_i$ is given by the winding number of the phase of $\prod_k(q_k\sigma + m_k)$.
where we have used the conventions of [30]. Defining the central charge $Z$ of the supersymmetry algebra by

$$\{Q_+, \tilde{Q}_-\} = 2(H - P), \quad \{Q_-, \tilde{Q}_-\} = 2(H + P),$$
$$\{Q_+, \tilde{Q}_-\} = 2iZ, \quad \{Q_+, \tilde{Q}_-\} = -2i\tilde{Z},$$

the equation (8) may be re-written as a relation between the central charge and the gauge / flavor charges:

$$Z = -i\left(\sigma + \sum_k \frac{m_k q_k}{q^2}\right) Q_0 - i \sum_{i,k} m_k \beta_{k,i} Q_i .$$

The bar on $Z$ in equation (9) has been used to denote complex conjugation. Using

$$Q_0 \Phi_k = q_k \Phi_k, \quad Q_i \Phi_k = \alpha_{i,k} \Phi_k ,$$

and the definition (1) of $\beta$, we can check that equation (8) is indeed satisfied for the chiral fields $\Phi_k$.

For states coming from quantizing the phase space of fields on $S^1$, $Q_0$ is always zero:

$$Z = -i \sum_{i,k} m_k \beta_{k,i} Q_i .$$

Note that the central charge $Z$ gives a lower-bound for the mass $m$ of $S^1$ states, i.e., $m \geq |Z|$. BPS states are defined to be states that saturate this bound. A massive BPS multiplet consists of two components, as opposed to the four of a long multiplet [20].

Meanwhile, in the IR theory, the central charge $Z$ of the supersymmetry algebra can be computed to be [9, 12, 32]

$$Z = \Delta \tilde{W}(\sigma) ,$$

where $\Delta \tilde{W}(\sigma)$ denotes the integral of $\partial_\sigma \tilde{W}(\sigma)$ along the spatial slice. Now when $\tilde{W}$ is single valued for given values of the twisted chiral fields, the only way $Z$ can be non-zero is when the spatial slice is a line and $\sigma$ interpolates between the saddles of $\tilde{W}$ from one end of the line to the other [9, 12]. In this case, states on $S^3$ cannot have a non-trivial central charge. Meanwhile, when $\tilde{W}$ is multivalued with respect to $\sigma$, and the different values can be approached by continuous variations of the fields, $\Delta \tilde{W}$ can have non-trivial values even on compact spatial slices, such as $S^1$ [10, 11]. The twisted superpotential of the effective $U(1)$ theory in question is precisely of this nature [29]. In fact, on $S^3$, the central charge is related to the winding numbers around $P_k$ by

$$Z = \Delta \tilde{W} = -\frac{i}{2\pi} \sum_k m_k \Delta(\arg(q_k \sigma + m_k))$$

due to the superpotential (2). Again, we stress that for $S^1$ states, the winding numbers are restricted by the Gauss constraint (5) which is crucial for arriving at the above equation. Equating the equations (12) and (14), we arrive at the identification (4).
We thus have derived that the flavor charges of the UV gauge theory become topological charges, or winding numbers, of the IR theory. We have also derived the BPS central charge of states in $S^1$ with respect to the topological charges in equation (14).

### III. SECOND EXAMPLE: WORLDVOLUME THEOREY OF A DYNAMICAL SURFACE OPERATOR

Our next example is that of a “dynamical surface operator” (DSO) in a 4d $\mathcal{N} = 2$ SU($N$) supersymmetric gauge theory [23–27]. Our dynamical surface operator theories come from a slight modification of the class of surface operators [33–35] studied in [28]. The surface operators of [28] are 2d defects of the 4d theory, whose world-volume degrees of freedom consist of a $U(1)$ vector field and $N$ chiral multiplets, with a Fayet-Iliopoulos term $\mathcal{W} = t\Sigma$. As before, $\Sigma$ is the field strength multiplet of the vector field. The surface operator theory becomes coupled to the bulk theory by coupling the adjoint scalar field of the 4d vector multiplet as a twisted mass of the SU($N$) flavor symmetry of the chiral multiplets in the 2d theory. The dynamical surface operator theory is obtained by promoting the FI parameter $t$ to a twisted chiral superfield, which we denote $T$. While many aspects of the theory of the DSO depends on the details of how the FI parameter is made dynamical, the topological charges and the central charge of the supersymmetry algebra do not depend on these details, but only on the effective twisted superpotential of the theory, which has been computed in [28]. Let us study the topological charges of the $S^1$ states of this theory, and relate them to the central charge of the supersymmetry algebra.

The effective dynamical surface operator theory is obtained by moving to a point $u$ in the Coulomb branch of the 4d theory and integrating out all the massive fields of the 4d and 2d theory at that point. As a result of [28], the effective theory of a DSO then becomes a 2d sigma model into the Seiberg-Witten curve $\Sigma_u$ [23, 24] of the 4d theory at $u$, which is given by an $N$-fold cover of the complex $t$-plane. The IR theory has a twisted superpotential [28, 36]:

$$\Delta \mathcal{W} = \sum_{i=1}^{N-1} (n_ia^i + m_ia_D,i) + \sum_{F=1}^{R_F} s_F m_F, \quad (17)$$

where $a^i(u)$ and $a_D,i(u)$ are the electric-magnetic charges, while $m_F$ are the twisted masses for the 4d flavor symmetries [23, 24, 28]. This follows from the definition of $a^i$, $a_D,i$ as integrals of $\lambda_{SW,u}$ over the electric and magnetic cycles of the Riemann surface, and $m_F$ as the residue of the Seiberg-Witten differential at $P_F$. As a result, the charges and the mass formula of the BPS states of this 2d theory on $S^1$ coincide with the charges and the mass formula for the BPS particles of the 4d theory on $R^3$.

### IV. BPS STATES WITH TOPOLOGICAL CHARGES

A natural question to ask in light of our results is how to calculate the spectrum of BPS states on $S^1$. The BPS spectrum, however, is expected to be rather non-robust. To be more precise, we expect the BPS spectrum of the two-dimensional theory to depend on the details of the spatial slice. For example, it is clear that the BPS spectrum will depend on the spin structure of the compact space $S^1$. Unless the spin structure is fixed to be
Ramond-Ramond (RR), the \( \mathcal{N} = (2, 2) \) supersymmetry is broken by boundary conditions. More surprisingly, we can see that the spectrum with RR spin structure jumps as the radius of \( S^1 \) varies, even for a theory as simple as the free theory with a linear superpotential. We exhibit that the BPS spectra change drastically with respect to the dimensionless central charge \( r \), where \( r \) is the radius of the spatial circle.

This may be a cause of alarm for some, as BPS ground states of a sigma model into \( X \) can be understood as elements of a particular cohomology of \( \mathcal{L}X \), the free loop space of \( X \) [13, 14]. We show that this is no longer true for massive BPS states. Given that the theory has non-trivial topological charges, the loop space \( \mathcal{L}X \) decomposes into disconnected components \( \mathcal{L}X|_{\tilde{q} = \tilde{w}} \), one for each topological sector of charge \( \tilde{w} \). A massive BPS state of charge \( \tilde{w} \) is a differential form in \( \mathcal{L}X|_{\tilde{q} = \tilde{w}} \), annihilated by a differential operator \( \Delta_{\text{BPS}} \) that we construct shortly. The BPS ground states, which lie in the topological sector \( \mathcal{L}X|_{\tilde{q} = \tilde{w}} \), are defined to be differential forms annihilated by the positive definite Laplacian operator constructed from supercharges, which correspond to linear operators \( D \) and \( D^* \) acting on differential forms in the loop space. 3 Thus the ground states \( \Psi \) of the theory must be “harmonic” in the supercharges:

\[
D\Psi = D^*\Psi = 0. \tag{18}
\]

This is why they represent elements of the cohomology of \( \mathcal{L}X|_{\tilde{q} = \tilde{w}} \). Meanwhile, the operator \( \Delta_{\text{BPS}} \) that annihilates massive BPS states is not positive semi-definite. While the basis of massive BPS states can be organized such that each element \( \Psi_\alpha \) is annihilated by a differential operator \( Q_\alpha = e^{i\theta_\alpha}D + e^{-i\theta_\alpha}D^* \), \( \Psi_\alpha \) is not annihilated by \( Q^*_\alpha \). Thus these states are not elements of the \( D \)-cohomology, and are not guaranteed to be stable under deformations of the theory.

### A. The free theory

Let us now consider a theory with one twisted chiral multiplet \( Y \) with periodicity \( Y \sim Y + 2\pi si \) and twisted superpotential \( \hat{W} = MY \). This theory is a sigma-model into a flat cylinder. We take \( s \) to be an arbitrary real number. The topological charge of the states on \( S^1 \) is given by the winding number \( w \) around the imaginary direction of \( Y \), and the central charge of the supersymmetry algebra is given by

\[
Z = \Delta\hat{W} = 2\pi iMsw. \tag{19}
\]

Meanwhile, the twisted superpotential merely adds a constant \( |M|^2 \) to the Lagrangian of the theory. Free theories of periodic superfields are well understood. In particular, at generic values of the radius of \( S^1 \), the free theory does not have any states of mass \( 2\pi |M|sw \) as we see shortly. Furthermore, the theory is devoid of any classical BPS winding configurations. When the radius \( r \) of the \( S^1 \) satisfies

\[
|M|r = ws \tag{20}
\]

for some \( w \in \mathbb{Z} \), however, there exist classical time-independent BPS configurations with winding number \( \pm w \) whose mass saturates the BPS bound.

Let us examine the quantum \( S^1 \) states of this theory with RR spin structure. The spectrum of the quantum theory is well known, and is explained in great detail in standard texts [37, 38]. The states are constructed from the “ground states” \( |p; n, w; i, j \rangle \) that are labeled by three numbers—the momentum \( p \) in the non-compact direction, the discrete momentum \( n \) and the winding number \( w \) in the compact direction—and the spinor indices \( i, j \). These states are in the \( 2 \times 2 \) representation of \( \text{Spin}(2) \).

All states of the quantum theory can be obtained by acting on the ground states in a given momentum-winding sector with creation operators of massive modes on \( S^1 \).

The mass of a state in a momentum-winding sector labeled by \( (n, w) \) then satisfies

\[
m^2 \geq \pi^2 r^2 \left( \frac{n^2}{s^2 r^2} - \frac{w^2 s^2}{r^2} + |M|^2 \right)^2 + 4\pi^2 w^2 s^2 |M|^2, \tag{21}
\]

where the inequality is saturated if and only if \( p = 0 \) and the state is a ground state in the \( (n, w) \) sector. What this equation shows is that for fixed winding number \( w \), the BPS bound is saturated if and only if

\[
|M|r = \sqrt{w^2 s^2 - \frac{n^2}{s^2}} \tag{22}
\]

for some integer \( n \). Now the momentum of this state is given by \( P = 2\pi nw/r \), hence we see that the condition for there to be a time-independent BPS state \( (n = 0) \) is precisely given by the classical formula (20). While topologically charged BPS field configurations are not, in general, guaranteed to survive as BPS states in the quantum theory [11], in the simple case of the free theory, we see they do.

Let us note that nothing special happens at the radius (22)—no new states are introduced to the spectrum, or taken away. At this radius, the four states \( |0; n, w; i, j \rangle \), with fixed \( n \) and \( w \), happen to have mass \( 2\pi |M|sw| \) and split into two BPS multiplets, whereas at a generic radius, these states form one long representation of the supersymmetry algebra. It is clear that for the free theory, the spectrum of BPS states change with \( r \), and in fact, for generic \( r \), there are no BPS states at all.

From this example, we see that massive BPS states on \( S^1 \) can appear and disappear as the radius of the spatial

---

3 Here we momentarily convert to describing theories with \( \mathcal{N} = (1, 1) \) supersymmetry for simplicity of presentation. The supercharges are identified with modified versions of the exterior derivative \( d \) and its dual \( d^* \) that act on differential forms of \( \mathcal{L}X \) in this case. In \( \mathcal{N} = (2, 2) \) theories, the supercharges are modified versions of Dolbeault operators and their duals, as we present at the end of the section.
slice is tuned, and that there may be no BPS states at certain, or even most radii. This does not violate any index theorem, as the BPS states appear and disappear in pairs. In fact, this is something expected, as the Cecotti-Fendley-Intriligator-Vafa (CFIV) index $\text{Tr} F(-1)^F$ [20], which is specialized to counting massive BPS states, vanishes on the torus due to CPT invariance [21]. This implies that $S^1$ states with topological charge, even if they exist, come in pairs and cancel out in the index, just as in the free theory.

Such behavior of the states can be attributed to the fact that the massive BPS states cannot be identified as elements of a cohomology, unlike the zero-energy ground states of the theory. This can be explicitly demonstrated for the free theory studied above. All the salient features can be exhibited, in fact, with a $\mathcal{N} = (1,1)$ theory obtained by only retaining the compact scalar field $\phi \sim \phi + 2\pi s$ and a single Majorana fermion [9]. The linear superpotential is $-iM\phi$ of the theory is now real, i.e., $M$ is a real mass. We now have a $\mathcal{N} = (1,1)$ supersymmetric sigma model into a circle. The states of these theories are constructed from ground states

$$|n,w\rangle, \psi_0|n,w\rangle$$

(23)

that are labelled by the momentum and the winding number as before, except now the RR-vacuum has degeneracy-two. We have made the presence of the fermion zero mode $\psi_0$ explicit. Note that $\psi_0^2 = 1$. The states are built by acting on the vacua by real oscillators $\alpha_{-l}$ and $\psi_{-l}$:

$$\left(\prod_{l=1}^{\infty} \alpha_{-l}^{n_l} \psi_{-l}^{f_l}\right) \psi_0^{|n,w\rangle}.$$  

(24)

The powers of the fermion oscillator $f_l$ for $l > 0$ are restricted to be less than two, for the state to not vanish.

These states, which form a basis for the wave function of the theory, can be understood as complex-valued differential forms on the free loop space $\mathcal{L}S^1$ of the circle, which is just the space of all the maps from the spatial circle of the quantum field theory to the target space. We thus use the term “states” and “differential forms” interchangeably. Any such map $\phi$ can be decomposed into Fourier components:

$$\phi(x) = \phi_0 + ws(x) + \sum_{l=1}^{\infty} \phi_l \sin \frac{2\pi lx}{r}.$$ 

(25)

Now the free loop space decomposes into discrete components $\mathcal{L}S^1_w$, labelled by the winding number $w$:

$$\mathcal{L}S^1_w = S^1 \times \mathbb{R}_1 \times \mathbb{R}_2 \times \cdots.$$ 

(26)

The coefficients $\phi_l$ are the coordinates on this infinite dimensional space. In particular, $\phi_0$ spans the target circle. A particular basis of differential forms on this space consists of the forms

$$e^{2\pi in\phi_0/s} \phi_0^f \wedge \left( \prod_{l=1}^{\infty} \Psi_{l,n_l}(\phi_l) d\phi_l^f \right).$$ 

(27)

Here, $\Psi_{l,n_l}$ is the level-$n_l$ eigenfunction of the harmonic oscillator of mass $l$. The differential forms (27) precisely correspond to the eigenstates (24) of the free theory.

Let us now understand how the massive BPS states of the theory are characterized. By examining the supersymmetry operator, we see that the BPS states should be in the ground state of the non-compact directions. The only relevant geometry is the circle $S^1$ of radius $s$ in $\mathcal{L}S^1_w$. We now focus our attention on the component of the wave function of the theory along the $S^1$ direction, i.e., differential forms on $S^1$.

The real supersymmetry generators $Q_1$ and $Q_2$ satisfy the algebra [13]

$$Q_1^2 = H - P, \quad Q_2^2 = H + P, \quad \{Q_1, Q_2\} = 4\pi wsM$$

(28)

in the sector with winding number $w$. The supersymmetry operators are differential operators on the forms in the loop space. Restricting to the differential forms along the $S^1$, the operators can be identified. Writing [13]

$$Q_1 = \frac{i}{\sqrt{2\pi}} D + i^{-1/2} D^*, \quad Q_2 = i^{-1/2} D + i^{1/2} D^*,$$

(29)

we find that

$$D = d + ws\psi_0 + M\phi_0, \quad D^* = d^* + ws\phi_0 \wedge + M\psi_0,$$

(30)

where $d$ is the exterior derivative acting on differential forms. Here we have set $r = 1$ and absorbed it into $M$, for notational simplicity. This is a slight generalization to an equivariant differential of [13]—the “connection” $M\phi_0$ has been further added to the equivariant differential with respect to the killing vector field along the circle. The star superscript acting on an operator $O$ denotes its dual defined by

$$\int O^* \alpha \wedge \ast \beta \equiv \int \alpha \wedge \ast O \beta,$$

(31)

where the star operator is used to denote the operation

$$(\ast \eta)_{i_1 \cdots i_{n-k}} = \frac{1}{k!} \sqrt{\text{det} g} \epsilon^{i_1 \cdots i_{n-k}} \epsilon_{j_1 \cdots j_{n-k}} \eta_{j_1 \cdots j_{n-k}}$$

(32)

for differential forms on an $n$-manifold. 4 In particular, for the differential operator $d$,

$$d^* = \ast d \ast$$

in one dimension.

---

4 While the star operator of this equation can be identified with the standard definition of the Hodge star operator [39] for real differential forms, the action of the two operators on complex differential forms differ by a complex conjugation of the components.
The operator $\iota_{\partial_\phi_0}$ denotes the interior product with the Killing vector $\partial_\phi_0$. It is simple to check the following operator relations:

\[ D^* D + DD^* = d^* d + dd^* + M^2 + w^2 s^2, \]
\[ D^2 = w s \mathcal{L}_{\phi_0} + M w s, \quad (D^*)^2 = -w s \mathcal{L}_{\phi_0} + M w s. \]  

(33)

$\mathcal{L}_{\phi_0}$ is the Lie derivative along $\partial_\phi_0$. These operators, along with $(DD^* - D^2)$, mutually commute. An easy way to check this is to use the fact that $D^2 + (D^*)^2$ is central. It follows that both $D$ and $D^*$ commute with $D^2$ and $(D^*)^2$. This is enough to verify the claim above.

Now the Hamiltonian and the momentum operator are given by

\[ H = 2\pi (D^* D + DD^*) \]
\[ P = 2\pi i \{ (D^*)^2 - D^2 \} = -2\pi i w s \mathcal{L}_{\phi_0}. \]  

(34)

The zero-energy states of this Hamiltonian are elements of the cohomology defined by the operator $D$. Since $d^* d + dd^*$ is a positive semi-definite operator, $H$ cannot be zero unless $M = w = 0$. Therefore the $D$-cohomology is empty in topologically charged sectors. On the other hand when $M = w = 0$, the $D$-cohomology is nontrivial—it is just the ordinary cohomology of the circle, and has two elements. These two elements are the ground states of the theory with $M = 0$.

The massive BPS states cannot be elements of the empty $D$-cohomology. Rather, they are defined as forms annihilated by the operator:

\[ \Delta_{BPS} = DD^* - D^* D = -\frac{i}{4\pi} (Q_1 Q_2 - Q_2 Q_1). \]  

(35)

This is due to the relation

\[ 4\pi^2 \Delta_{BPS}^2 = H^2 - P^2 - (2\pi w s M)^2, \]  

(36)

i.e., the BPS bound is saturated for the mass of states with $\Delta_{BPS} = 0$. Note that $H$, $P$ and $\Delta_{BPS}$ mutually commute and are Hermitian—the BPS states are hence taken to be eigenstates of $P$ as well as of $H$. A consequence of (36) is that a simultaneous eigenstate of $H$ and $P$ automatically is also an eigenstate of $\Delta_{BPS}$.

The BPS states can also be recognized in a more standard way, i.e., as states being annihilated by a linear combination of supercharges. Given an eigenstate $\Psi_{h,p}$ of $H$ and $P$,

\[ \Delta_{BPS} \Psi_{h,p} = 0 \]  

(37)

if and only if

\[ (e^{i\theta} D + e^{-i\theta} D^*) \Psi_{h,p} = 0 \]  

(38)

for $\theta$ such that

\[ e^{2i\theta} = \frac{2\pi w s M + i p}{\hbar}. \]  

(39)

While the proof is standard, we have added it in the appendix for sake of completeness.

As noted, the eigenstates on the circle are given by the differential forms

\[ e^{2\pi i n/\hbar} d\phi_0, \quad e^{2\pi i n/\hbar} s \phi_0, \]  

(40)

for integer $n$. From (36), we find that a BPS state of the free theory at hand must satisfy

\[ \frac{n^2}{s^2} - w^2 s^2 + M^2 = 0 \]  

(41)

for integers $n$ and $w$, as we have obtained before in the Hamiltonian picture. We thus recover the result that BPS states can only exist for values of $|M| r$ that satisfy the condition (22).

B. The general case

What we have said so far can be applied, with some modification, to topologically massive BPS states of sigma models with $N = (1, 1)$ supersymmetry in general. $\mathcal{L}_X$, the free loop space of $X$ decomposes into components $\mathcal{L}_X | _{Q = \bar{w}}$, where $\bar{w}$ labels the topological charges, or equivalently, winding numbers. The supersymmetry operators can be constructed out of differential operators on $\mathcal{L}_X | _{Q = \bar{w}}$. To be more precise, the relations (29) hold for the differential operators $D$ in the free loop space of the target manifold:

\[ D \equiv d + \iota_{v_K} + A^u \wedge . \]  

(42)

$v_K$ is the Killing vector inherited from the isometry along the spatial circle of the 2d theory. $A^u$ is the dual one-form to a vector field $u$, i.e.,

\[ A^u \wedge = \iota_u. \]  

(43)

These operators imply the supersymmetry algebra with central charge $Z$ (28), given that $A^u$ satisfies

\[ \mathcal{L}_{v_K} A^u = 0, \quad dA^u = 0. \]  

(44)

The vector field $v_K$ and the relevant one-form $A^u$ can be explicitly written for the cases of interest, i.e., in topologically non-trivial components of the loop space $\mathcal{L}_X$, and the properties (44) can be explicitly verified. The details of this computation are presented in appendix B. By definition of the Lie derivative, it follows that the pairing

\[ \iota_{v_K} A^u = Z \]  

(45)

is constant. In topologically nontrivial sectors with $Z \neq 0$, the cohomology with respect to $D$ is trivial since $\{D, D^*\} \geq |Z| > 0$. Meanwhile, there may still exist BPS states, i.e., forms annihilated by

\[ \Delta_{BPS} = DD^* - D^* D. \]  

(46)

As in the free case, a massive BPS eigenstate $\Psi_\alpha$ of $H$ and $P$ is annihilated by an operator

\[ e^{i\theta_\alpha} D + e^{-i\theta_\alpha} D^*. \]  

(47)
Let us end by generalizing what we have learned about \( \mathcal{N} = (1,1) \) theories to theories with \( \mathcal{N} = (2,2) \) supersymmetry. The target space \( X \) of an \( \mathcal{N} = (2,2) \) sigma model is Kähler, and the free loop space \( \mathcal{L}X \) inherits this structure. Let us construct the supersymmetry algebra of a component \( \mathcal{L}X|_{\bar{q}=\bar{a}} \) with non-trivial topological charge from linear forms, which involve the Dolbeault operators \( \partial \) and \( \bar{\partial} \).

Let us consider a Killing vector field \( v \) on the Kähler “manifold” \( \mathcal{L}X|_{\bar{a}} \). The vector \( v \) preserves the complex structure, and is decomposable into holomorphic and anti-holomorphic Killing vectors \( V \) and \( \bar{V} \):

\[
v = V + \bar{V}, \quad \{\iota V, \bar{\partial}\} = \{\iota V, \partial\} = 0. \tag{48}
\]

The vector fields may be written locally as \( V = V^I \partial_I \), \( \bar{V} = V^I \bar{\partial}_I \), where \( I \) and \( \bar{I} \) label the local holomorphic and anti-holomorphic coordinates \( z^I \) and \( \bar{z}^I \) of \( \mathcal{L}X|_{\bar{a}} \). Since \( d = \partial + \bar{\partial} \), it follows that

\[
\{\iota V, \partial\} = \mathcal{L}_V, \quad \{\iota\bar{V}, \bar{\partial}\} = \bar{\mathcal{L}}_V. \tag{49}
\]

Since \( V \) and \( \bar{V} \) themselves are Killing vectors,

\[
\mathcal{L}_V = -\mathcal{L}_V, \quad \mathcal{L}^*_V = -\bar{\mathcal{L}}_V. \tag{50}
\]

The \( \mathcal{N} = (2,2) \) supersymmetry operators on \( \mathcal{L}X|_{\bar{a}} \) can be constructed by using a flat connection

\[
A^U = U_I dz^I \tag{51}
\]

on \( \mathcal{L}X|_{\bar{a}} \), and the Killing vector \( v_K = V + \bar{V} \) inherited from the isometry of \( S^1 \).

\[
A^U \wedge = \iota^*_U, \quad (U_I = G_{IJ} U^J) \tag{52}
\]

for a vector field \( U \) with only components with holomorphic indices, i.e., \( U = U^I \partial_I \). Here, \( G_{IJ} = G_{JI} \) are the componenets of the Kähler metric on \( \mathcal{L}X \). Given that the connection \( A^U \) satisfies

\[
\mathcal{L}_V A^U = \mathcal{L}_V A^U = 0, \quad \bar{\partial} A^U = \bar{\partial} A^U = 0, \tag{53}
\]

the pairing

\[
Z \equiv (-2i)\iota V A^U = (-2i)\iota U A^\bar{V} \tag{54}
\]

is a constant complex number, while \( \mathcal{L}_{v_K} A^U = \mathcal{L}_{v_K} A^U = 0 \). For \( \mathcal{N} = (2,2) \) non-linear sigma models into Kähler manifolds with holomorphic superpotentials, the Killing vectors and flat connections can be written explicitly, and the conditions (53) can be shown to hold, following similar steps to the proof of the properties (44). This is demonstrated in appendix B.

Let us now define the differential operators

\[
\mathcal{D} = \partial + i\iota V + A^U \wedge, \quad \mathcal{D}^\dagger = \partial + iA^U \wedge + iU, \tag{55}
\]

where we have modified equivariant Dolbeault operators [18, 19] by a connection. The dagger denotes the adjoint action on an operator \( \mathcal{O} \) such that

\[
\int \mathcal{O}^\dagger \wedge \ast \bar{\mathcal{O}} \equiv \int \ast \wedge \bar{\mathcal{O}} \wedge \mathcal{O}. \tag{56}
\]

Note that \( \mathcal{O}^\dagger = \mathcal{O}^\dagger \) for real operators, by which we mean operators such that for any real differential form \( \beta \), \( \mathcal{O} \beta \) is also real. It is useful to note that \( \partial^\dagger = (\bar{\partial})^\ast \) and \( \bar{\partial}^\dagger = (\partial)^\ast \). We then arrive at the commutation relations

\[
\{\mathcal{D}, \mathcal{D}^\dagger\} = \{\mathcal{D}, \mathcal{D}^\dagger\} = H, \quad \{\mathcal{D}, \mathcal{D}^\ast\} = -\{\mathcal{D}^\dagger, \mathcal{D}\} = iP \equiv \mathcal{L}_{v_K}, \quad \mathcal{D}^2 = (\mathcal{D}^\dagger)^2 = iZ/2, \quad \bar{\mathcal{D}}^2 = (\mathcal{D}^\ast)^2 = -i\bar{Z}/2, \tag{57}
\]

while the anti-commutators \( \{\mathcal{D}, \mathcal{D}^\dagger\} \) and \( \{\bar{\mathcal{D}}, \bar{\mathcal{D}}^\dagger\} \) vanish. The Hamiltonian \( H \) is given by

\[
2H = \Delta + |v_K|^2 + |u|^2 + \{d, A^\nu \wedge \} + \{d, A^\nu \wedge \}^\ast + \{d, \iota_u\} + \{d, \iota_{u^\ast}\}^\ast, \tag{58}
\]

where we have defined \( u = U + \bar{U} \). Details of the derivation of these relations are given in appendix B. Defining the operators

\[
\mathcal{Q}_+ = i^{1/2} \mathcal{D} + i^{-1/2} \mathcal{D}^\dagger, \quad \mathcal{Q}_+ = i^{1/2} \mathcal{D} + i^{-1/2} \mathcal{D}^\dagger, \quad \mathcal{Q}_- = i^{1/2} \mathcal{D}^\dagger + i^{-1/2} \mathcal{D}, \quad \mathcal{Q}_- = i^{1/2} \mathcal{D}^\dagger + i^{-1/2} \mathcal{D}^\dagger, \tag{59}
\]

we find that they satisfy the supersymmetry algebra (9) with all other anti-commutators vanishing. 5

When \( Z \) is non-zero, the operators \( \mathcal{D} \) or \( \mathcal{D}^\dagger \) do not define a cohomology, due to the last line of (57). In particular, there are no states that are annihilated by the Hamiltonian \( \mathcal{H} \). There exists, however, a quadratic Hermitian operator that annihilates the BPS states given by

\[
\Delta_{BPS} = D_\zeta D_\zeta^\dagger - D_\zeta^\dagger D_\zeta \tag{60}
\]

where \( 2\zeta \) is the phase of \( iZ \), i.e, \( iZ = |Z|e^{2i\zeta} \), while

\[
D_\varphi \equiv e^{-i\varphi} \mathcal{D} + e^{i\varphi} \mathcal{D}^\dagger, \quad D_\varphi \equiv e^{i\varphi} \mathcal{D} + e^{-i\varphi} \mathcal{D}^\dagger. \tag{61}
\]

Since \( \Delta_{BPS} \) is Hermitian and

\[
\Delta_{BPS}^2 = 4(\mathcal{H}^2 - P^2 - |Z|^2), \tag{62}
\]

the condition that a state is annihilated by \( \Delta_{BPS} \) is equivalent to it having mass \( |Z| \), as desired. Furthermore, following similar steps to the \( \mathcal{N} = (1,1) \) case, an

5 We see that the bar used on the supersymmetry operators actually correspond to taking the adjoint operation on the differential operators, rather than complex conjugation. Hence the notation \( \mathcal{Q}_+ \) and \( \mathcal{Q}_- \) is misleading, although we have chosen to use it for sake of consistency with the literature.
eigenstate $\Psi_{h,p}$ of $H$ and $P$ that is BPS must be annihilated by the two Hermitian operators

$$e^{i\theta}D_\zeta + e^{-i\theta}D_\zeta^\dagger,$$  
$$e^{-i(\theta - \frac{2\pi}{h})}D_{(\zeta^+\zeta^-)} + e^{i(\theta - \frac{2\pi}{h})}D_{(\zeta^+\zeta^-)}$$

(63)

with $e^{2i\theta} = (ip - |Z|)/\hbar$ and vice versa.

Hence the existence of real $a,b$ $\Psi$ annihilates $\Psi_{h,p}$. Hence the existence of real $a,b$ $\Psi$ annihilates $\Psi_{h,p}$.

Appendix A: The BPS condition as a linear constraint

In this section, we show that given a eigenstate $\Psi_{h=p}$ of $H$ and $P$, that the condition

$$\Delta_{BPS}\Psi_{h,p} = 0$$

(A1)

is equivalent to the condition that there exist real $a$ and $b$ such that

$$Q(a,b) \equiv aQ_1 + bQ_2$$

(A2)

annihilates $\Psi_{h,p}$.

Let us consider the action of $Q(a,b)$ on complex-valued differential forms. Using the definitions (29) and (30) we find:

$$\int Q(a,b)\phi \wedge \bar{Q}(a,b)\phi = \int Q(a,b)^2 \phi \wedge \bar{\phi}$$

(A3)

Therefore $Q(a,b)^2$ is a positive semi-definite operator and

$$Q(a,b)^2\Psi_{h,p} = 0 \iff Q(a,b)\Psi_{h,p} = 0.$$  

(A4)

By the supersymmetry algebra, we can show that

$$Q(a,b)^2\Psi_{h,p} = [(h-p)a^2 + 4\pi Mwsab + (h+p)b^2] \Psi_{h,p}.$$  

(A5)

Hence the existence of real $a,b$ for which

$$Q(a,b)^2\Psi_{h,p} = 0,$$  

(A6)

is equivalent to the condition

$$h^2 - p^2 - (2\pi wsM)^2 \leq 0.$$  

(A7)

The left hand side of this equation is precisely given by $4\pi^2\Delta^2_{BPS}$:

$$\Delta^2_{BPS} \leq 0.$$  

(A8)

Recall that the eigenstate $\Psi_{h,p}$ of $H$ and $P$ has to be an eigenstate of $\Delta^2_{BPS}$. Since $\Delta_{BPS}$ is Hermitian, we find that this is equivalent to

$$\Delta_{BPS}\Psi_{h,p} = 0.$$  

(A9)

Combining this with the result (A4), we arrive at our claim.

It is useful to note that defining the angle

$$\theta = \frac{\pi}{4} + \arg(a - ib),$$

(A10)

we find that

$$e^{2i\theta} = i (\frac{a^2 - b^2 - 2iab}{a^2 + b^2}) = \frac{2\pi wsM + ip}{h}$$

(A11)

and the operator $Q(a,b)$ can be written as

$$Q(a,b) = \sqrt{a^2 + b^2}(e^{i\theta}D + e^{-i\theta}D^*)$$

(A12)

Appendix B: The differential geometry of loop space

In this appendix, we present some relevant facts about the differential geometry of the loop space $\mathcal{L}X$. In particular, we write explicit expressions for vector fields and one-forms in loop space that are relevant for defining the supersymmetry operators, and verify that they have desirable properties. In particular, we show some identities necessary for arriving at the commutation relations (28) and (57) of differential operators defined in $\mathcal{L}X$.

Let us denote the real bosonic fields mapping into the target space $X$ as $\phi^\mu(s)$, where $s$ is the coordinate on the unit circle. The pair $(\mu,s)$ constitutes a coordinate index in the infinite dimensional manifold $\mathcal{L}X$, while the values $\phi^\mu(s)$ are real coordinates on this space. A vector field $V$, thus, has the component expression

$$V = \int_{S^1} ds V^\mu(s) \partial_{\phi^\mu(s)},$$

(B1)

while a one-form $A$ can be written as

$$A = \int_{S^1} ds A_{\mu,s} \delta \phi^\mu(s).$$

(B2)

The sum over the repeated indices are assumed. The coordinate dependence of the components $V^\mu(s)$ and $A_{\mu,s}$ are implicit. The differential operator $d$ acts on the one-form $A$ as

$$dA = \int_{S^1} ds d\phi^\nu(s) A_{\mu,s} \delta \phi^\nu(s) \wedge \delta \phi^\mu(s).$$

(B3)

and similarly on differential forms in general. The metric on $\mathcal{L}X$ is defined by a pull-back from the target space $X$:

$$V \cdot W(\phi(s)) = \int_{S^1} ds V^\nu(s) W^\mu(s) G_{\mu\nu}(\phi(s)).$$

(B4)
In components, the metric can be written as
\[ G_{(\mu,s)(\nu,s')} (\phi(s)) = G_{\mu\nu}(\phi(s)) \delta(s-s'). \] (B5)

Now the components of the Killing vector \( v_K \), defined by the pull-back of the action of the translation along the circle to the loop space, can be explicitly written as
\[ v_K = \int_{S^1} ds \frac{d\phi^\mu(s)}{ds} \partial_{\phi^\mu(s)}. \] (B6)

The one-form \( A^u \) used in defining the supersymmetry algebra is given by
\[ A^u = \int_{S^1} ds \partial_{\mu} \mathcal{V}(\phi(s)) \delta \phi^\mu(s), \] (B7)

where \( \mathcal{V} \) is the \( \mathcal{N} = (1,1) \) superpotential. The connection \( A^u \) is closed:
\[ dA^u = \int_{S^1} ds \partial_{\nu} \mathcal{V}(\phi(s)) \delta \phi^\nu(s) \wedge \delta \phi^\mu(s) = 0. \] (B8)

Also, by definition,
\[ \iota_{v_K} A^u = \int_{S^1} ds \frac{d\phi^\mu(s)}{ds} \partial_{\mu} \mathcal{V}(\phi(s)) = \Delta \mathcal{V} \] (B9)

is a constant determined by the topological winding number of the component \( \mathcal{L}X \big|_{\hat{q} = \omega} \) of the loop space. It follows that
\[ \mathcal{L}_{v_K} A^u = \{d, \iota_{v_K}\} A^u = 0. \] (B10)

We have thus proven the properties (44) of \( A^u \).

Let us now consider the case of a sigma model with \( \mathcal{N} = (2,2) \) supersymmetry. The target space \( X \), and correspondingly, the loop space \( \mathcal{L}X \) are now Kähler. Now \( \phi^i(s) \) denote the complex bosonic component of the (twisted) chiral fields, while \( i, j, \cdots \) and \( \bar{i}, \bar{j}, \cdots \) are used to index the holomorphic and anti-holomorphic coordinates, respectively. Now the pair of coordinates \((i, s)\) make up the holomorphic indices on \( \mathcal{L}X \), while \((\bar{i}, s)\) consist the anti-holomorphic indices. The Killing vector \( v_K = \bar{V} + \bar{V} \) splits into a sum of a holomorphic and anti-holomorphic Killing vector. \( V \) and \( \bar{V} \) can be explicitly written as
\[ V = \int_{S^1} ds \frac{d\phi^i(s)}{ds} \partial_{\phi^i(s)}, \quad \bar{V} = \int_{S^1} ds \frac{d\bar{\phi}^i(s)}{ds} \partial_{\bar{\phi}^i(s)}. \] (B11)

The one-form \( A^U \) in equation (55) is given by
\[ A^U = \int_{S^1} ds \partial_{\mu} \bar{\mathcal{W}}(\phi(s)) \delta \phi^\mu(s), \] (B12)

while \( A^U = \bar{A}^U \) for the (twisted) superpotential \( \bar{\mathcal{W}} \). Recall that \( \bar{\mathcal{W}} \) is a holomorphic function of the complex fields \( \phi^i \). Using these definitions, the relations (53) can be proven by following the steps taken in the \( \mathcal{N} = (1,1) \) case. First of all,
\[ \bar{\delta} A^\bar{U} = \int_{S^1} ds \bar{\partial}_j \bar{\mathcal{W}} \delta \phi^j(s) \wedge \delta \phi^i(s) = 0, \]
\[ \partial A^U = \int_{S^1} ds \partial_j \bar{\mathcal{W}} \delta \phi^j(s) \wedge \delta \phi^i(s) = 0. \] (B13)

Meanwhile, \( \iota_{\bar{V}} A^\bar{U} = 0 \) while
\[ \iota_V A^U = \int_{S^1} ds \frac{d\phi^i(s)}{ds} \partial_{\phi^i(s)} \bar{\mathcal{W}}(\phi(s)) = \Delta \bar{\mathcal{W}}, \] (B14)

which is constant in each component of \( \mathcal{L}X \). Thus (53) follows.

Some additional identities need to be shown in order to arrive at the commutation relations (57). In order to show the vanishing of the commutators \( \{\mathcal{D}, \bar{\mathcal{D}}^\dagger\} \) and \( \{\mathcal{D}, \bar{\mathcal{D}}\} \), the following must hold:
\[ \{\partial, A^\bar{V} \wedge \} = (\partial A^\bar{V}) \wedge = 0, \quad \{\partial, \iota_{\bar{U}}\} + \{\partial, \iota_U\}^* = 0. \] (B15)

The first identity follows from the fact that the target manifold is Kähler, that is:
\[ \partial A^\bar{V} = \int_{S^1} ds \partial_k \left( G_{ij} \frac{d\phi^j(s)}{ds} \right) \delta \phi^k(s) \wedge \delta \phi^i(s) = \int_{S^1} ds \left( \partial_k \partial_i \partial_j \mathcal{K} \right) \frac{d\phi^j(s)}{ds} \delta \phi^k(s) \wedge \delta \phi^i(s) = 0. \] (B16)

Here the fact that the Kähler metric is given by \( G_{ij} = \partial_i \partial_j \mathcal{K} \) for the Kähler potential \( \mathcal{K} \) has been used.

The condition \( \partial A^U = 0 \) is enough to ensure that the second equation of (B15) holds. Let us denote all coordinate indices of \( \mathcal{L}X \) using \( M, N, \cdots \) while using the letters \( I, J, K, L \) and \( \bar{I}, \bar{J}, \bar{K}, \bar{L} \) to denote holomorphic and anti-holomorphic indices, respectively. These indices have a continuous range, and the sum/integral over the repeated indices are assumed in the equations to follow. We also denote the holomorphic (anti-holomorphic) local coordinates by \( z^I (\bar{z}^\bar{I}) \), etc. The action of \( \{\partial, \iota_U\} \) on a differential form \( T \) with components \( T_{M_1, M_2, \ldots} \) is then given by
\[ \left[ \{\partial, \iota_U\} T \right]_{M_1, M_2, \ldots} = U^I \partial_I T_{M_1, M_2, \ldots} + \sum_{M_r \text{ holomorphic index}} \left( \partial_{\bar{M}_r} U^I \right) T_{M_1, \ldots, M_{r-1}, M_r, M_{r+1}, \ldots} \] (B17)

Recall that the components of \( A^U = U_I d\bar{z}^{\bar{I}} \) are related to the components of the vector \( U = U^I \partial_I \) by \( U_I = G_{IJ} U^J \) while \( \partial_I U_J = 0 \) for all pairs of \( I \) and \( J \). Using this fact and the fact that the only non-zero Levi-Civita connections of a Kähler manifold are given by
\[ \Gamma_{\bar{J} \bar{K}} = -G_{K \bar{L}} \partial_j G^{\bar{L} \bar{L}}, \quad \Gamma^{\bar{I}}_{\bar{J} \bar{K}} = -G_{\bar{K} \bar{L}} \partial_j G^{I \bar{L}}, \] (B18)
we arrive at
\[ \{\partial, \iota_U\} T = U^M \nabla_M T. \] (B19)
It can also be shown using the same set of facts that
\[ \nabla_M U^M = 0. \quad (B20) \]

Equations (B19) and (B20) imply the equality \( \{ \partial, \iota_U \} = -\{ \partial, \iota_U \}^* \), since
\[
\int (U^M \nabla_M \alpha) \wedge * \beta =
- \int (\nabla_M U^M)(\alpha \wedge * \beta) - \int \alpha \wedge * (U^M \nabla_M \beta). \quad (B21)
\]

In order to show that the commutation relation
\[ \{ D, D^\dagger \} = [D, D^\dagger] = H \quad (B22) \]
holds, the following equalities must also be verified:
\[ \{ \partial, A \wedge \} = \{ \partial, A \wedge \}^*, \quad \{ \partial, \iota_U \} = \{ \partial, \iota_U \}^*. \quad (B23) \]
The first of these equations follows from the fact that \( v \alpha \)
is a Killing vector, i.e., \( \nabla_M (v \alpha) + \nabla \alpha (v \beta) = 0 \). This implies that
\[ \partial A^V = \partial_i V^j dz^I \wedge d\bar{z}^J = \partial_j \bar{V}^j d\bar{z}^J \wedge dz^I = \bar{\partial} A^V. \quad (B24) \]

Meanwhile, the action of the operator \( \{ \bar{\partial}, \iota_U \} \) on a differential form \( T \) is given by
\[
[\{ \bar{\partial}, \iota_U \} T]_{M_1 M_2 \cdots} = \sum_{M_r : \text{anti-holomorphic index}} (\bar{\partial}_{M_r} U^I) T_{M_1 \cdots M_{r-1} I M_{r+1} \cdots}. \quad (B25)
\]

Using the flatness of \( A^U \), this equation can be rewritten as
\[
[\{ \bar{\partial}, \iota_U \} T]_{M_1 M_2 \cdots} = \sum_r (\nabla^M U^M_r) T_{M_1 \cdots M_{r-1} I M_{r+1} \cdots}. \quad (B26)
\]

From this definition and the definition of the action of * on operators, it follows that
\[
[\{ \bar{\partial}, \iota_U \}^* T]_{M_1 M_2 \cdots} = \sum_r (\nabla^M U^M_r) T_{M_1 \cdots M_{r-1} I M_{r+1} \cdots}. \quad (B27)
\]

Meanwhile, the flatness of \( A^U \) along with equation (B18) is enough to arrive at
\[ \nabla_M U^M = \begin{cases} \bar{\partial}_j U^I & \text{when } M_r = \bar{J} \text{ and } M = I \\ 0 & \text{otherwise}, \end{cases} \quad (B28) \]
that is, \( \nabla_M U^M \) vanishes unless \( M_r \) is an anti-holomorphic index and \( M \) is a holomorphic index. Comparing equations (B25), (B27) and (B28), we arrive at the second identity of equation (B23).
