RUNNING TITLE: Superselection and Constraints.

Abstract
For systems which contain both superselection structure and constraints, we study compatibility between constraining and superselection. Specifically, we start with a generalisation of Doplicher-Roberts superselection theory to the case of nontrivial centre, and a set of Dirac quantum constraints and find conditions under which the superselection structures will survive constraining in some form. This involves an analysis of the restriction and factorisation of superselection structures. We develop an example for this theory, modelled on interacting QED.

1 Introduction
In heuristic quantum field theory, there are many examples of systems which contain global charges (hence superselection structure) as well as a local gauge symmetry (hence constraints). Most of these systems cannot currently be written in a consistent mathematical framework, due to the presence of interactions. Nevertheless, the mathematical structure of superselection by itself has been properly developed (cf. [6, 2, 5]), as well as the mathematical structure of quantum constraints [12, 15, 18], hence one can at least abstractly consider systems which contain both. This will be the focus of our investigations in this paper. We will address the natural intertwining questions for the two structures, as well as compatibility issues.

There is a choice in how the problem of superselection with constraints is posed mathematically. We will be guided by the most important physics example in this class, which is that of a quantized local gauge field, acting on a fermion field. It has a Gauss law constraint (implementing the local gauge transformations) as well as a set of global charges (leading to superselection).

The architecture of the paper is as follows, in Sect. 2 we give a brief summary of the superselection theory which we intend to use here. We include recent results concerning the case of an observable algebra with nontrivial centre (cf. [4]), and some new results on the field algebra. In Sect. 3 we give a summary of quantum constraints, and in Sect. 4 we collect our main results. The proofs for these are in Sect. 6, and in Sect. 5 we present an example.

2 Fundamentals of superselection
In this section we summarize the structures from superselection theory which we need. For proofs, we refer to the literature if possible.

The superselection problem in algebraic quantum field theory, as stated by the Doplicher–Haag–Roberts (DHR) selection criterion, led to a profound body of work, culminating in the
general Doplicher–Roberts (DR) duality theory for compact groups. The DHR criterion selects
a distinguished class of “admissible” representations of a quasilocal algebra \(\mathcal{A}\) of observables,
where the centre is trivial, i.e. \(Z(A) = \mathbb{C}1\), or even \(\mathcal{A}\) is assumed to be simple. This corresponds
to the selection of a DR–category \(\mathcal{T}\) of “admissible” endomorphisms of \(\mathcal{A}\). Furthermore, from
this endomorphism category \(\mathcal{T}\) the DR–analysis constructs a C*-algebra \(\mathcal{F} \supseteq \mathcal{A}\) together with
a compact group action \(\alpha : \mathcal{G} \ni g \to \alpha_g \in \text{Aut} \mathcal{F}\) such that

- \(\mathcal{A}\) is the fixed point algebra of this action,
- \(\mathcal{T}\) coincides with the category of all “canonical endomorphisms” of \(\mathcal{A}\) (cf. Subsection 2.3).

\(\mathcal{F}\) is called a Hilbert extension of \(\mathcal{A}\) in [5]. Physically, \(\mathcal{F}\) is identified as a field algebra
and \(\mathcal{G}\) with a global gauge group of the system. \(\{\mathcal{F}, \alpha_G\}\) is uniquely determined by \(\mathcal{T}\) up to
\(\mathcal{A}\)-module isomorphisms. Conversely, \(\{\mathcal{F}, \alpha_G\}\) determines uniquely its category of all canonical
endomorphisms. Therefore one can state the equivalence of the “selection principle”, given by
\(\mathcal{T}\) and the “symmetry principle”, given by \(\mathcal{G}\). This duality is one of the crucial theorems of
the Doplicher-Roberts theory.

In contrast to the original theory of Doplicher and Roberts, we allow here a nontrivial centre
for \(\mathcal{A}\). The reason for this is that when there are constraints present, the system contains
nonphysical information, so there is no physical reason why \(\mathcal{A}\) should be simple. Only after
eliminating the constraints should one require the final observable algebra to be simple, hence
having trivial centre. Now a duality theorem for a C*-algebra with nontrivial centre has been
proven recently [3, 25], establishing a bijection between distinguished categories of endomorphisms
of \(\mathcal{A}\) and Hilbert extensions of \(\mathcal{A}\) satisfying some additional conditions, of which the most
important is: \(\mathcal{A}' \cap \mathcal{F} = Z(\mathcal{A})\) (i.e. the relative commutant is assumed to be minimal). This will
be properly explained below. This condition has already been used by Mack and Schomerus [19]
as a “new principle”.

2.1 Basic properties of Hilbert systems

Below \(\mathcal{F}\) will always denote a unital C*-algebra. A Hilbert space \(\mathcal{H} \subset \mathcal{F}\) is called algebraic
if the scalar product \(\langle \cdot, \cdot \rangle\) of \(\mathcal{H}\) is given by \(\langle A, B \rangle \mathbb{1} := A^*B\) for \(A, B \in \mathcal{H}\). Henceforth we
consider only finite-dimensional algebraic Hilbert spaces. The support \(\text{supp} \mathcal{H}\) of \(\mathcal{H}\) is defined
by \(\text{supp} \mathcal{H} := \sum_{j=1}^d \Phi_j \Phi_j^*\) where \(\{\Phi_j | j = 1, \ldots, d\}\) is any orthonormal basis of \(\mathcal{H}\). Unless
otherwise specified, we assume below that each algebraic Hilbert space \(\mathcal{H}\) considered, satisfies
\(\text{supp} \mathcal{H} = \mathbb{1}\).

We also fix a compact C*-dynamical system \(\{\mathcal{F}, \mathcal{G}, \alpha\}\), i.e. \(\mathcal{G}\) is a compact group and
\(\alpha : \mathcal{G} \ni g \to \alpha_g \in \text{Aut} \mathcal{F}\) is a pointwise norm-continuous morphism. For \(\gamma \in \mathcal{G}\) (the dual of \(\mathcal{G}\))
its spectral projection \(\Pi_\gamma \in \mathcal{L}(\mathcal{F})\) is defined by

\[
\Pi_\gamma(F) := \int_{\mathcal{G}} \chi_\gamma(g) \alpha_g(F) \, dg \quad \text{for all } F \in \mathcal{F},
\]

where:

\[
\chi_\gamma(g) := \dim \gamma \cdot \text{Tr} \pi(g), \quad \pi \in \gamma
\]

and its spectral subspace \(\Pi_\gamma \mathcal{F}\) satisfies \(\Pi_\gamma \mathcal{F} = \text{clo-span}\{\mathcal{L} \subset \mathcal{F}\}\) where \(\mathcal{L}\) runs through
all invariant subspaces of \(\mathcal{F}\) which transform under \(\alpha_G\) according to \(\gamma\) (cf. [8]). Define the
spectrum of \(\alpha_G\) by

\[
\text{spec } \alpha_G := \{\gamma \in \hat{\mathcal{G}} \mid \Pi_\gamma \neq 0\}.
\]

Our central object of study is:

2.1 Definition The C*–dynamical system \(\{\mathcal{F}, \mathcal{G}, \alpha\}\) is called a Hilbert system if for each
\(\gamma \in \hat{\mathcal{G}}\) there is an algebraic Hilbert space \(\mathcal{H}_\gamma \subset \mathcal{F}\), such that \(\alpha_G\) acts invariantly on \(\mathcal{H}_\gamma\), and
the unitary representation \(\mathcal{G} \uparrow \mathcal{H}_\gamma\) is in the equivalence class \(\gamma \in \hat{\mathcal{G}}\).
2.2 Remark Note that for a Hilbert system \( \{ F, G, \alpha \} \) we have necessarily that the algebraic Hilbert spaces satisfy \( H_\gamma \subset \Pi_\gamma F \) for all \( \gamma \), and hence that \( \text{spec } \alpha_G = \hat{G} \), i.e. the spectrum is full. The morphism \( \alpha : G \to \text{Aut } F \) is necessarily faithful. So, since \( G \) is compact and \( \text{Aut } F \) is Hausdorff w.r.t. the topology of pointwise norm-convergence, \( \alpha \) is a homeomorphism of \( G \) onto its image. Thus \( G \) and \( \alpha_G \) are isomorphic as topological groups.

We are mainly interested in Hilbert systems whose fixed point algebras coincide such that they appear as extensions of it.

2.3 Definition A Hilbert system \( \{ F, G, \alpha \} \) is called a Hilbert extension of a C*-algebra \( A \subset F \) if \( A \) is the fixed point algebra of \( G \). Two Hilbert extensions \( \{ F_i, G, \alpha_i \} \), \( i = 1, 2 \) of \( A \) (w.r.t. the same group \( G \)) are called \( A \)-module isomorphic if there is an isomorphism \( \tau : F_1 \to F_2 \) such that \( \tau(A) = A \) for \( A \in A \), and \( \tau \) intertwines the group actions, i.e. \( \tau \circ \alpha_1^g = \alpha_2^g \circ \tau \).

2.4 Remark (i) Group automorphisms of \( G \) lead to \( A \)-module isomorphic Hilbert extensions of \( A \), i.e. if \( \{ F, G, \alpha \} \) is a Hilbert extension of \( A \) and \( \xi \) an automorphism of \( G \), then the Hilbert extensions \( \{ F, G, \alpha \} \) and \( \{ F, G, \alpha \circ \xi \} \) are \( A \)-module isomorphic. So the Hilbert system \( \{ F, G, \alpha \} \) depends, up to \( A \)-module isomorphisms, only on \( \alpha_G \), which is isomorphic to \( G \). In other words, up to \( A \)-module isomorphism we may identify \( G \) and \( \alpha_G \subset \text{Aut } F \) neglecting the action \( \alpha \) which has no relevance from this point of view. Therefore in the following, unless it is otherwise specified, we use the notation \( \{ F, G \} \) for a Hilbert extension of \( A \), where \( G \subset \text{Aut } F \).

(ii) As mentioned above, examples of Hilbert systems arise in DHR–superselection theory cf. [5, 2]. There are also constructions by means of tensor products of Cuntz algebras (cf. [7]). In these examples the relative commutant of the fixed point algebra \( A \), hence also its center, is trivial. Another construction for \( G = T \), by means of the loop group \( C^\infty(S^1, T) \) is in [21], and for this \( Z(A) \) is nontrivial.

2.5 Remark A Hilbert system \( \{ F, G \} \) is a highly structured object; we list some important facts and properties (for details, consult [2, 5]):

(i) The spectral projections satisfy:

\[
\Pi_\gamma_1 \Pi_\gamma_2 = \Pi_\gamma_2 \Pi_\gamma_1 = \delta_{\gamma_1 \gamma_2} \Pi_\gamma_1,
\]

\[
\|\Pi_\gamma\| \leq d(\gamma)^{3/2}, \quad d(\gamma) := \dim(H_\gamma),
\]

\[
\Pi_\gamma F = \text{span}(A H_\gamma), \quad \Pi_\gamma F = A,
\]

where \( \iota \in \hat{G} \) denotes the trivial representation of \( \hat{G} \).

(ii) Each \( F \in F \) is uniquely determined by its projections \( \Pi_\gamma F, \gamma \in \hat{G} \), i.e. \( F = 0 \) iff \( \Pi_\gamma F = 0 \) for all \( \gamma \in \hat{G} \), cf. Corollary 2.6 of [25].

(iii) A useful *-subalgebra of \( F \) is

\[
F_{\text{fin}} := \left\{ F \in F \mid \Pi_\gamma F \neq 0 \quad \text{for only finitely many } \gamma \in \hat{G} \right\}
\]

which is dense in \( F \) w.r.t. the C*-norm (cf. [20]).
(iv) In \( \mathcal{F} \) there is an \( \mathcal{A} \)-scalar product given by \( \langle F, G \rangle_{\mathcal{A}} := \Pi_{\gamma} F G^* \), w.r.t. which the spectral projections are symmetric, i.e. \( \langle \Pi_{\gamma} F, G \rangle_{\mathcal{A}} = \langle F, \Pi_{\gamma} G \rangle_{\mathcal{A}} \) for all \( F, G \in \mathcal{F} \), \( \gamma \in \hat{\mathcal{G}} \). Using the \( \mathcal{A} \)-scalar product one can define a norm on \( \mathcal{F} \), called the \( \mathcal{A} \)-norm

\[
|F|_\mathcal{A} := \| \langle F, F \rangle_{\mathcal{A}} \|^{1/2}, \quad F \in \mathcal{F}.
\]

Note that \( |F|_\mathcal{A} \leq \| F \| \) and that \( \mathcal{F} \) in general is not closed w.r.t. the \( \mathcal{A} \)-norm. Then for each \( F \in \mathcal{F} \) we have that \( F = \sum_{\gamma \in \hat{\mathcal{G}}} \Pi_{\gamma} F \) where the sum on the right hand side is convergent w.r.t. the \( \mathcal{A} \)-norm but not necessarily w.r.t. the \( \mathcal{C}^* \)-norm \( \| \cdot \| \). We also have Parseval’s equation: \( \langle F, F \rangle_{\mathcal{A}} = \sum_{\gamma \in \hat{\mathcal{G}}} \langle \Pi_{\gamma} F, \Pi_{\gamma} F \rangle_{\mathcal{A}} \), cf. Proposition 2.5 in [5]. Moreover \( |\Pi_{\gamma}|_\mathcal{A} = 1 \) for all \( \gamma \in \hat{\mathcal{G}} \), where \( | \cdot |_\mathcal{A} \) denotes the operator norm of \( \Pi_{\gamma} \) w.r.t. the norm \( | \cdot |_A \) in \( \mathcal{F} \).

(v) Generally for a Hilbert system, the assignment \( \gamma \to \mathcal{H}_{\gamma} \) is not unique. If \( U \in \mathcal{A} \) is unitary then also \( U \mathcal{H}_{\gamma} \subset \Pi_{\gamma} \mathcal{F} \) is a \( \mathcal{G} \)-invariant algebraic Hilbert space carrying the representation \( \gamma \in \hat{\mathcal{G}} \). Each \( \mathcal{G} \)-invariant algebraic Hilbert space \( \mathcal{K} \) which carries the representation \( \gamma \) is of this form, i.e. there is a unitary \( V \in \mathcal{A} \) such that \( \mathcal{K} = V \mathcal{H}_{\gamma} \).

For a general \( \mathcal{G} \)-invariant algebraic Hilbert space \( \mathcal{H} \subset \mathcal{F} \), we may have that \( \mathcal{G} \uparrow \mathcal{H} \) is not irreducible, i.e. it need not be of the form \( \mathcal{K} = V \mathcal{H}_{\gamma} \). Below we will consider further conditions on the Hilbert system to control the structure of these.

(vi) Given two \( \mathcal{G} \)-invariant algebraic Hilbert spaces \( \mathcal{H}, \mathcal{K} \subset \mathcal{F} \), then \( \text{span}(\mathcal{H} \cdot \mathcal{K}) \) is also a \( \mathcal{G} \)-invariant algebraic Hilbert space which we will briefly denote by \( \mathcal{H} \cdot \mathcal{K} \). It is a realization of the tensor product \( \mathcal{H} \otimes \mathcal{K} \) within \( \mathcal{F} \) and carries the tensor product of the representations of \( \mathcal{G} \) carried by \( \mathcal{H} \) and \( \mathcal{K} \) in the obvious way.

(vii) Let \( \mathcal{H}, \mathcal{K} \) be two \( \mathcal{G} \)-invariant algebraic Hilbert spaces, but not necessarily of support 1. Then there is a natural isometric embedding \( \mathcal{J} : \mathcal{L}(\mathcal{H}, \mathcal{K}) \to \mathcal{F} \) given by

\[
\mathcal{J}(T) := \sum_{j,k} t_{j,k} \Psi_j \Phi_k^*, \quad t_{j,k} \in \mathbb{C}, \quad T \in \mathcal{L}(\mathcal{H}, \mathcal{K})
\]

where \( \{ \Phi_k \}_k, \{ \Psi_j \}_j \) are orthonormal bases of \( \mathcal{H} \) and \( \mathcal{K} \) respectively, and where

\[
T(\Phi_k) = \sum_j t_{j,k} \Psi_j;
\]

i.e. \( (t_{j,k}) \) is the matrix of \( T \) w.r.t. these orthonormal bases. One has

\[
T(\Phi) = \mathcal{J}(T) \cdot \Phi, \quad \Phi \in \mathcal{H}.
\]

This implies: if \( T_j \in \mathcal{L}(\mathcal{H}_j, \mathcal{K}_j) \), \( j = 1, 2 \), hence \( T_1 \otimes T_2 \in \mathcal{L}(\mathcal{H}_1 \mathcal{H}_2, \mathcal{K}_1 \mathcal{K}_2) \), then \( \mathcal{J}(T_1 \otimes T_2) \Phi_1 \Phi_2 = \mathcal{J}(T_1) \Phi_1 \mathcal{J}(T_2) \Phi_2 \) for \( \Phi_j \in \mathcal{H}_j \).

Moreover \( \mathcal{J}(T) \in \mathcal{A} \) iff \( T \in \mathcal{L}_\mathcal{G}(\mathcal{H}, \mathcal{K}) \), where \( \mathcal{L}_\mathcal{G}(\mathcal{H}, \mathcal{K}) \) denotes the linear subspace of \( \mathcal{L}(\mathcal{H}, \mathcal{K}) \) consisting of all intertwining operators of the representations of \( \mathcal{G} \) on \( \mathcal{H} \) and \( \mathcal{K} \) (cf. p. 222 [5]).

2.2 The category of \( \mathcal{G} \)-invariant algebraic Hilbert spaces

The \( \mathcal{G} \)-invariant algebraic Hilbert spaces \( \mathcal{H} \) of \( \{ \mathcal{F}, \mathcal{G} \} \) form the objects of a category \( \mathcal{T}_\mathcal{G} \) associated to \( \{ \mathcal{F}, \mathcal{G} \} \) whose arrows are given by the elements of \( (\mathcal{H}, \mathcal{K}) := \mathcal{J}(\mathcal{L}_\mathcal{G}(\mathcal{H}, \mathcal{K})) \subset \mathcal{A} \).

It is already large enough to carry all tensor products of the representations of \( \mathcal{G} \) on its objects by Remark 2.5(vi) (though not necessarily subrepresentations and direct sums). First, let us state some of its rich structure (cf. [5] [7]):
2.6 Proposition For \{\mathcal{F}, \mathcal{G}\} the category \(\mathcal{T}_G\) is a tensor C*-category, i.e. the arrow spaces \((\mathcal{H}, \mathcal{K})\) are Banach spaces such that

- w.r.t. composition of arrows \(R, S\) we have \(\|R \circ S\| \leq \|R\|\|S\|\),
- there is an antilinear involutive contravariant functor \(* : \mathcal{T}_G \to \mathcal{T}_G\) such that \(\|R^* \circ R\| = \|R\|^2\) for all arrows \(R\) with the same range and domain (here the functor \(*\) is given by the involution in \(\mathcal{F}\))
- There is an associative product \(\cdot\) on \(\text{Ob}\mathcal{T}_G\) and an identity object \(1 \in \text{Ob}\mathcal{T}_G\) (i.e. \(1 \cdot \mathcal{H} = \mathcal{H} = \mathcal{H} \cdot 1\)) and there is an associative bilinear product \(\times\) of the arrows, such that if \(R \in (\mathcal{H}, \mathcal{K})\) and \(R' \in (\mathcal{H}', \mathcal{K}')\) then \(R \times R' \in (\mathcal{H} \cdot \mathcal{H}', \mathcal{K} \cdot \mathcal{K}')\). Moreover we require that for \(R, R'\) as above:

\[
1_x \times R = R \times 1_x = R, \quad (R \times R')^* = R^* \times R'^*,
\]  

(1)

where \(1_x \in (1, 1)\) is the identity arrow, as well as the interchange law

\[
(S \circ R) \times (S' \circ R') = (S \times S') \circ (R \times R'),
\]

whenever the left hand side is defined.

Here in \(\mathcal{T}_G\), the product \(\cdot\) is given by the product of \(\mathcal{F}\), the identity object is \(1 := \mathbb{C}1\) and the product \(\times\) is defined by

\[
R \times R' := J(T \otimes T'),
\]

for \(R = J(T), R' = J(T')\), where \(T \in \mathcal{L}_G(\mathcal{H}, \mathcal{K}), T' \in \mathcal{L}_G(\mathcal{H}', \mathcal{K}')\). Note that \((1, 1) = (\mathbb{C}1, \mathbb{C}1) = \mathbb{C}1\), i.e. \(1_x = 1\).

\(\mathcal{T}_G\) has additional important structures (permutation and conjugation), which we will consider below in Subsection 2.7.

We need to examine conditions to require of \{\mathcal{F}, \mathcal{G}\} to ensure that \(\mathcal{T}_G\) carries subrepresentations and direct sums.

2.7 Definition Let \(\mathcal{H}, \mathcal{K} \in \text{Ob} \mathcal{T}_G\), and define \(\mathcal{H} \prec \mathcal{K}\) to mean that there is an orthoprojection \(E\) on \(\mathcal{K}\) such that \(E \mathcal{K}\) is invariant w.r.t. \(\mathcal{G}\) and the representation \(\mathcal{G} \uparrow E\mathcal{K}\) is unitarily equivalent to \(\mathcal{G} \uparrow \mathcal{K}\). Call \(\mathcal{H}\) a subobject of \(\mathcal{K}\).

It is easy to see that \(\prec\) is a partial order. Note that \(\mathcal{H} \prec \mathcal{K}\) iff there is an isometry \(V \in \mathcal{L}_G(\mathcal{H}, \mathcal{K})\) such that \(VV^* = : E\) is a projection of \(\mathcal{K}\), i.e. \(V \mathcal{H} = E \mathcal{K}\). Then \(J(V) \in \mathcal{A}\) and \(E \mathcal{K} = J(V) \cdot \mathcal{H}\).

If \(E \in \mathcal{L}_G(\mathcal{K})\) is an orthoprojection \(0 < E < 1\), i.e. \(E\) is a reducing projection for the representation of \(\mathcal{G}\) on \(\mathcal{K}\), then the question arises whether there is an object \(\mathcal{H}\) such that the representations on \(\mathcal{H}\) and \(E \mathcal{K}\) are unitarily equivalent. This suggests the concept of closedness of \(\mathcal{T}_G\) w.r.t. subobjects.

2.8 Definition The category \(\mathcal{T}_G\) is closed w.r.t. subobjects if to each \(\mathcal{K} \in \text{Ob} \mathcal{T}_G\) and to each nontrivial orthoprojection \(E \in \mathcal{L}_G(\mathcal{K})\) there is an isometry \(\tilde{V} \in \mathcal{A}\) with \(\tilde{V} \tilde{V}^* = J(E)\). In this case \(\mathcal{H} := \tilde{V}^* \cdot \mathcal{K}\) is a subobject \(\mathcal{H} \prec \mathcal{K}\) assigned to \(E\), where \(\tilde{V} = J(V)\) for some isometry \(V \in \mathcal{L}_G(\mathcal{H}, \mathcal{K})\) with \(VV^* = E\).

Next, we consider when an object of \(\mathcal{T}_G\) carries the direct sum of the representations of two other objects. If \(V, W \in \mathcal{A}\) are isometries with \(VV^* + WW^* = 1\) and \(\mathcal{H}, \mathcal{K} \in \text{Ob} \mathcal{T}_G\), then we call the algebraic Hilbert space \(V \mathcal{H} + W \mathcal{K}\) of support 1 a direct sum of \(\mathcal{H}\) and \(\mathcal{K}\). It is \(\mathcal{G}\)-invariant and carries the direct sum of the representations on \(\mathcal{H}\) and \(\mathcal{K}\) but in general depends on the choice of isometries \(V, W\). We define
2.9 Definition (i) The category $\mathcal{T}_G$ is closed w.r.t. direct sums if to each $H_1, H_2 \in \text{Ob} \mathcal{T}_G$ there is an object $K \in \text{Ob} \mathcal{T}_G$ and there are isometries $V_1, V_2 \in A$ with $V_1V_1^* + V_2V_2^* = 1$ such that $K = V_1H_1 + V_2H_2$ (then $V_1 \in (H_1, K)$ and $V_2 \in (H_2, K)$ follow).

(ii) A C*-algebra $A$ satisfies Property B if there are isometries $V_1, V_2 \in A$ such that $V_1V_1^* + V_2V_2^* = 1$. A Hilbert system $\{F, G\}$ is said to satisfy Property B if its fixed point algebra $A := \Pi_{\mathcal{F}}$ satisfies Property B.

2.10 Remark For a Hilbert system $\{F, G\}$ we have:

(i) It satisfies Property B iff $\mathcal{T}_G$ is closed w.r.t. direct sums.

(ii) For nonabelian $G$, the category $\mathcal{T}_G$ is closed w.r.t. subobjects iff it is closed w.r.t. direct sums iff it has Property B cf. Prop. 3.5 of [25].

(iii) In the case that $G$ is abelian, the theory simplifies. This is because we already have Pontryagin’s duality theorem, hence it is not necessary to consider closure under subobjects and direct sums to obtain a duality theory.

2.3 The category of canonical endomorphisms

The main aim of DR–theory is to obtain an intrinsic structure on $A$ from which we can reconstruct the Hilbert system $\{F, G\}$ in an essentially unique way. Here we want to transport the rich structure of $\mathcal{T}_G$ to $A$.

2.11 Definition To each $G$–invariant algebraic Hilbert space $H \subset F$ there is assigned a corresponding inner endomorphism $\rho_H \in \text{End} F$ given by

$$\rho_H(F) := \sum_{j=1}^{d(H)} \Phi_j F \Phi_j^* ,$$

where $\{\Phi_j | j = 1, \ldots, d(H)\}$ is any orthonormal basis of $H$. Note that $\rho_H$ preserves $A$. A canonical endomorphism is the restriction of an inner endomorphism to $A$, i.e. it is of the form $\rho_H|A \in \text{End} A$.

2.12 Remark (i) The definition of the canonical endomorphisms uses $F$ explicitly. The question arises whether the canonical endomorphisms can be characterised by intrinsic properties within $A$. This interplay between the $\rho_H$ and the $\rho_H|A$ plays an essential role in the DR-theory. Below, we omit the restriction symbol and regard the $\rho_H$ also as endomorphisms of $A$.

(ii) If the emphasis is only on the representation $\gamma$ and not on its corresponding algebraic Hilbert space $H_\gamma$, we will write $\rho_\gamma$ instead of $\rho_{H_\gamma}$.

(iii) Note that $\Phi A = \rho_H(A)\Phi$ for all $\Phi \in H$ and $A \in A$.

(iv) Note that the identity endomorphism $\iota$ is assigned to $H = \mathbb{C} 1$, i.e. $\rho_{\mathbb{C} 1} := \iota$.

(v) Let $H, K$ be as before, then $\rho_H \circ \rho_K = \rho_{H\cap K}$.

(vi) The map $\rho$ from $\text{Ob} \mathcal{T}_G$ to the canonical endomorphisms is in general not injective. In fact we have: if $H, K \in \text{Ob} \mathcal{T}_G$, then $\rho_H|A = \rho_K|A$ iff $\Psi^* \Phi \in A' \cap F$ for all $\Phi \in H, \Psi \in K$, cf. Prop. 3.9 in [25].
2.13 Definition Define $\mathcal{T}$ to be the category with objects the canonical endomorphisms, and arrows the intertwiner spaces, where the intertwiner space of canonical endomorphisms $\sigma, \tau \in \text{End} \mathcal{A}$ is:

$$(\sigma, \tau) := \{ X \in \mathcal{A} \mid X\sigma(A) = \tau(A)X \text{ for all } A \in \mathcal{A} \} .$$

and this is a complex Banach space. For $A \in (\sigma, \sigma')$, $B \in (\tau, \tau')$, we define $A \times B := A\sigma(B) \in (\sigma\tau, \sigma'\tau')$. We will say that $\sigma, \tau \in \text{End} \mathcal{A}$ are mutually disjoint if $(\sigma, \tau) = \{0\}$ when $\sigma \neq \tau$.

2.14 Remark

(i) We have $(\iota, \iota) = Z(\mathcal{A}) := \text{centre of } \mathcal{A}$.

(ii) The composition of two canonical endomorphisms (which corresponds to products of the generating Hilbert spaces, see Remark 2.13(v), i.e. to tensor products of representations) satisfies the correct compatibility conditions with the product $\times$ of intertwiners to ensure that $\mathcal{T}$ is a $C^*$-tensor category cf. Prop. 2.6 and [6]. The identity object is $\iota$.

(iii) Recall the isometry $J : L_G(\mathcal{H}, \mathcal{K}) \rightarrow \mathcal{A}$ encountered in Remark 2.8(vii). We claim that its image is in fact contained in $(\rho_\mathcal{H}, \rho_\mathcal{K})$. To see this, let $\Phi \in \mathcal{H}$, $A \in \mathcal{A}$ and $T \in L_G(\mathcal{H}, \mathcal{K})$.

Then

$$J(T)\rho_\mathcal{H}(A)\Phi = J(T)\Phi \cdot A = T(\Phi) \cdot A = \rho_\mathcal{K}(A)T(\Phi) = \rho_\mathcal{K}(A)J(T) \cdot \Phi$$

hence

$$J(T)\rho_\mathcal{H}(A) = \rho_\mathcal{K}(A)J(T)$$

i.e. $J(T) \in (\rho_\mathcal{H}, \rho_\mathcal{K})$ or

$$(\mathcal{H}, \mathcal{K}) = J(L_G(\mathcal{H}, \mathcal{K})) \subseteq (\rho_\mathcal{H}, \rho_\mathcal{K}).$$

In general, the inclusion is proper. Note that for $R \in (\mathcal{H}, \mathcal{K})$, $R' \in (\mathcal{H}', \mathcal{K}')$ we have $J(R \otimes R') = R\rho_\mathcal{H}(R')$, i.e. $\times$ restricted to the $(\mathcal{H}, \mathcal{K})$'s coincides with the definition of $\times$ in Proposition 2.6 of the category $T_G$.

Next we would like to define the concepts of subobject and direct sums on $\text{Ob} \mathcal{T}$ compatibly with those on $\text{Ob} T_G$ under the morphism $\rho$. Recall that $\mathcal{H} < \mathcal{K}$ iff we have an isometry $V \in L_G(\mathcal{H}, \mathcal{K})$ and a projection $E \in L_G(\mathcal{K})$ with $V\mathcal{H} = E\mathcal{K} = J(E) \cdot \mathcal{K} = J(V) \cdot \mathcal{H}$. Then by [2] we get that $J(V) \in (\rho_\mathcal{H}, \rho_\mathcal{K})$ and $J(E) \in (\rho_\mathcal{K}, \rho_\mathcal{K})$.

Note that if $\mathcal{L} = V\mathcal{H} + W\mathcal{K}$ for isometries $V, W \in \mathcal{A}$ with $VV^* + WW^* = 1$, then $V \in (\rho_\mathcal{H}, \rho_\mathcal{L})$ and $W \in (\rho_\mathcal{K}, \rho_\mathcal{L})$.

2.15 Definition

(i) $\tau \in \text{Ob} \mathcal{T}$ is a subobject of $\sigma \in \text{Ob} \mathcal{T}$, denoted $\tau < \sigma$, if there is an isometry $V \in (\tau, \sigma)$. In this case $\tau(\cdot) = V^*\sigma(\cdot)V$ and $VV^* =: E \in (\sigma, \sigma)$ follow.

(ii) $\lambda \in \text{Ob} \mathcal{T}$ is a direct sum of $\sigma, \tau \in \text{Ob} \mathcal{T}$, if there are isometries $V \in (\sigma, \lambda)$, $W \in (\tau, \lambda)$ such that

$$\lambda(\cdot) = V\sigma(\cdot)V^* + W\tau(\cdot)W^* .$$

2.16 Remark

(i) The subobject relation $\tau < \sigma$ is again a partial order, because $\tau < \sigma$ and $\sigma < \mu$ imply the existence of isometries $V \in (\tau, \sigma)$, $W \in (\sigma, \mu)$. Then $WV \in (\tau, \mu)$ is also an isometry, i.e. $\tau < \mu$.

(ii) A direct sum as defined above is only unique up to unitary equivalence, i.e. if $\lambda, \lambda'$ are direct sums of $\sigma, \tau \in \text{Ob} \mathcal{T}$, then there is a unitary $U \in (\lambda, \lambda')$.

(iii) We have $\rho_{V\mathcal{H} + W\mathcal{K}}(\cdot) = V\rho_\mathcal{H}(\cdot)V^* + W\rho_\mathcal{K}(\cdot)W^*$ where the isometries $V, W \in \mathcal{A}$ satisfy $VV^* + WW^* = 1$. Also, if $\mathcal{H} < \mathcal{K}$, then $\tau := \rho_\mathcal{H} < \rho_\mathcal{K} :=: \sigma$. However, this does not mean that the partial order $\tau < \sigma$ can be defined by $\mathcal{H} < \mathcal{K}$ because the transitivity can be violated for some choices of $\mathcal{H}, \mathcal{K}$ cf. Remark 2.12(vi).
The closedness of $\mathcal{T}$ w.r.t. direct sums is defined by the closedness of $\mathcal{T}_G$ w.r.t. direct sums. The closedness w.r.t. subobjects for $\mathcal{T}$ is defined by the closedness w.r.t. subobjects for $\mathcal{T}_G$ in the following sense: If

$$\lambda = \rho_H \in \text{Ob} \mathcal{T}$$

is given then for all $H$ satisfying (3) and to each nontrivial projection $E \in \mathcal{J}(\mathcal{L}_G(H))$ there is an isometry $V \in A$ with $VV^* = E$. Then

2.17 Proposition If $\{F, G\}$ is nonabelian and satisfies Property B then $\mathcal{T}$ is closed w.r.t. direct sums and subobjects.

2.4 Connection between $\mathcal{T}_G$ and $\mathcal{T}$ and further structures.

In the following we assume that $\{F, G\}$ satisfies Property B.

There is a very important relation between the two categories $\mathcal{T}_G$ and $\mathcal{T}$, obtained as follows. The two assignments $\rho : \text{Ob} \mathcal{T}_G \to \mathcal{T}$ (by $H \to \rho_H$) and $\mathcal{J} : \mathcal{L}_G((H, K)) \to (\rho_H, \rho_K)$ combine into a faithful categorical morphism from $\mathcal{T}_G$ to $\mathcal{T}$ which is compatible with direct sums and subobjects (cf. Remark 2.16(iii)) but is not full in general, i.e. the inclusion in Equation (2) is improper for some $H$ and $K$. If $A' \cap \mathcal{F} = \mathbb{C}1$, then this categorical morphism becomes an isomorphism, cf. Prop. 3.12 in [25].

The category $\mathcal{T}_G$ has the following additional structures ([8 7]):

2.18 Proposition For $\{F, G\}$ the category $\mathcal{T}_G$ satisfies:

1. it has a permutation structure, i.e. a map $\epsilon$ from $\text{Ob} \mathcal{T}_G \times \text{Ob} \mathcal{T}_G$ into the arrows such that
   
   (i) $\epsilon(H, K) \in (HK, KH)$ is a unitary.
   
   (ii) $\epsilon(H, K)\epsilon(K, H) = 1$.
   
   (iii) $\epsilon(1, H) = \epsilon(H, 1) = 1$.
   
   (iv) $\epsilon(HK, L) = \epsilon(H, L)\rho_H(\epsilon(K, L))$.
   
   (v) $\epsilon(H', K')A \times B = B \times A\epsilon(H, K)$ for all $A \in (H, H')$, $B \in (K, K')$.

For $\mathcal{T}_G$ the permutation structure is given by

$$\epsilon(H, K) := \mathcal{J}(\Theta(H, K)) = \sum_{j,k} \Psi_j^* \Phi_k^* \Phi_k$$

where $\Theta$ is the flip operator $H \otimes K \to K \otimes H$, and where $\{\Phi_k\}_k$, $\{\Psi_j\}_j$ are orthonormal bases of $H$ and $K$, respectively.

2. It has a conjugation structure i.e. for each $H \in \text{Ob} \mathcal{T}_G$ there is a conjugated object $\overline{H} \in \text{Ob} \mathcal{T}_G$, carrying the conjugated representation of $G$ and there are conjugate arrows $R_H(1, \overline{H}H)$, $S_H = \epsilon(\overline{H}, H)R_H$ such that

$$S_H^* \rho_H(R_H) = 1, \quad R_H^* \rho_H(S_H) = 1.$$ 

For $\mathcal{T}_G$ we have $R_H := \sum_j \overline{\gamma}_j$ and $\{\overline{\gamma}_j\}_j$ is an orthonormal basis of $\overline{H}$. If $H$ carries the representation $\oplus_j \gamma_j$, $\gamma_j \in \hat{G}$, then $\overline{H}$ is given by a direct sum of $H \overline{\gamma}_j$, where $\overline{\gamma}_j \in \hat{G}$ represents the conjugated representation of $\gamma_j$.

2.19 Remark Using the categorial morphism from $\mathcal{T}_G$ to $\mathcal{T}$ we equip $\mathcal{T}$ with the image permutation and conjugation structures of those on $\mathcal{T}_G$. Note that for the image permutation structure in $\mathcal{T}$, property (v) need not hold for all arrows (cf. Remark 2.16(iii)).
For the next definition, observe first that from the operation $s$ defined for an abstract tensor category (cf. Prop. 2.6), we can define isometries and projections in its arrow spaces, i.e. an arrow $V \in (\lambda, \tau)$ is an isometry if $V^* \circ V = 1_\lambda$, and an arrow $E \in (\lambda, \lambda)$ is a projection if $E = E^* = E \circ E$.

2.20 Definition An (abstract) DR-category is an (abstract) tensor $C^*$-category $\mathcal{C}$ with $(1, 1) = C \mathbb{1}$ which has a permutation and a conjugation structure, and has direct sums and subobjects, i.e. to all objects $\lambda, \sigma$ there is an object $\tau$ and isometries $V \in (\lambda, \tau)$, $W \in (\sigma, \tau)$ such that $VV^* + WW^* = 1_\tau$, and to each nontrivial projection $E \in (\lambda, \lambda)$ there is an object $\sigma$ and an isometry $V \in (\sigma, \lambda)$ such that $E = VV^*$.

If the Hilbert system $\{\mathcal{F}, \mathcal{G}\}$ satisfies Property B then $\mathcal{T}_\mathcal{G}$ is an example of a DR-category, but not necessarily $\mathcal{T}$ (since property (v) in Prop. 2.18 need not hold for all arrows). However, if additionally $\mathcal{A}' \cap \mathcal{F} = C \mathbb{1}$ holds then also $\mathcal{T}$ is a DR-category.

2.5 Duality Theorems

Unless otherwise specified, in the following we assume Property B for $\{\mathcal{F}, \mathcal{G}\}$ when $\mathcal{G}$ is non-abelian. The DR-theorem produces a bijection between pairs

$$\{\mathcal{A}, \mathcal{T}\} \quad \text{and} \quad \{\mathcal{F}, \mathcal{G}\},$$

where $\mathcal{T}$ is a DR-category of unital endomorphisms of the unital $C^*$-algebra $\mathcal{A}$ with $Z(\mathcal{A}) = C \mathbb{1}$, and $\{\mathcal{F}, \mathcal{G}\}$ is a Hilbert extension of $\mathcal{A}$ having trivial relative commutant, i.e. $\mathcal{A}' \cap \mathcal{F} = C \mathbb{1}$ (see [6, 27, 28]). The DR-theorem says that in the case of Hilbert extensions of $\mathcal{A}$ with trivial relative commutant, the category $\mathcal{T}$ of all canonical endomorphisms can indeed be characterized intrinsically by their abstract algebraic properties as endomorphisms of $\mathcal{A}$ and a corresponding bijection can be established.

In this subsection we want to state how to obtain such a bijection for $C^*$-algebras $\mathcal{A}$ with nontrivial center $Z \supset C \mathbb{1}$. A first problem is that the category $\mathcal{T}_\mathcal{G}$ and $\mathcal{T}$ need not be isomorphic anymore, cf. Remark 2.14(iv) and Remark 2.12(vi), since now we have $C \mathbb{1} \neq Z \subseteq \mathcal{A}' \cap \mathcal{F}$.

We will investigate in the following the class of Hilbert extensions $\{\mathcal{F}, \mathcal{G}\}$ with compact group $\mathcal{G}$ and where the relative commutant satisfies the following minimality condition

2.21 Definition A Hilbert system $\{\mathcal{F}, \mathcal{G}\}$ is called minimal if the condition

$$\mathcal{A}' \cap \mathcal{F} = Z(\mathcal{A}) \quad \text{(4)}$$

is satisfied.

Then we have cf. Prop. 4.3 of [25]:

2.22 Proposition Let $\{\mathcal{F}, \mathcal{G}\}$ be a given Hilbert system. Then $\mathcal{A}' \cap \mathcal{F} = Z(\mathcal{A})$ iff $(\rho_\gamma, \rho_{\gamma'}) = \{0\}$ for $\gamma \neq \gamma'$, i.e. iff the set $\{\rho_\gamma \mid \gamma \in \mathcal{G}\}$ is mutually disjoint.

Observe that in any Hilbert system, for each $\tau \in \text{Ob} \mathcal{T}$ the space $h_\tau := \mathcal{H}_\tau Z(\mathcal{A})$, (where $\mathcal{H}_\tau$ is a $\mathcal{G}$–invariant algebraic Hilbert space) is a $\mathcal{G}$–invariant right Hilbert $Z(\mathcal{A})$–module i.e. there is a nondegenerate inner product taking its values in $Z(\mathcal{A})$ and it is $\langle A, B \rangle = A^* B$. Now we have cf. Prop. 3.1 [4]:
2.23 Proposition Let \( \{F, G\} \) be a given minimal Hilbert system, then the correspondence \( \tau \leftrightarrow h_\tau \) is a bijection. Thus \( h_\tau = H_\tau Z(A) \) is independent of the choice of \( H_\tau \), providing that \( \tau = \rho_{H_\tau} \). This bijection satisfies the conditions
\[
\sigma \circ \tau \quad \longleftrightarrow \quad h_\sigma \cdot h_\tau
\]
\[
\lambda = (\text{Ad}V) \circ \sigma + (\text{Ad}W) \circ \tau \quad \longleftrightarrow \quad h_\lambda = V h_\sigma + W h_\tau.
\]

Thus for minimal Hilbert systems, the \( Z(A) \)-modules \( h_\tau \) are uniquely determined by their canonical endomorphisms \( \tau \), even though the choice of \( H_\tau \) is not unique. We are now interested in those choices of \( H_\tau \) which are compatible with products:

2.24 Definition A Hilbert system \( \{F, G\} \) is called regular if there is an assignment \( \sigma \to H_\sigma \) from \( \text{Ob } T \) to \( G \)-invariant algebraic Hilbert spaces in \( F \) such that
\[
(i) \quad \sigma = \rho_{H_\sigma}, \text{ i.e. } \sigma \text{ is the canonical endomorphism of } H_\sigma,
\]
\[
(ii) \quad \sigma \circ \tau \to H_\sigma \cdot H_\tau.
\]

In a minimal Hilbert system regularity means that there is a “representing” Hilbert space \( H_\tau \subset h_\tau \) for each \( \tau \) with \( h_\tau = H_\tau Z(A) \) such that the compatibility relation (ii) holds.

If a Hilbert system is minimal and \( Z(A) = \mathbb{C} \mathbb{I} \) then it is necessarily regular. Thus a class of examples which are trivially minimal and regular, is provided by DHR–superselection theory.

A nontrivial example of a minimal and regular Hilbert system is constructed in [25].

Then we obtain, cf. Theorem 4.9 of [25]:

2.25 Theorem Let \( \{F, G\} \) be a minimal and regular Hilbert system, then: \( T \) contains a \( C^* \)-subcategory \( T_C \) with the same objects, \( \text{Ob } T_C = \text{Ob } T \), and arrows \( (\sigma, \tau)_C := (H_\sigma, H_\tau) = \mathcal{J}(L_G(H_\sigma, H_\tau)) \subset (\sigma, \tau) \) such that:
\[
P.1 \quad T_C \text{ is a DR-category (in particular } (\iota, \iota)_C = \mathbb{C} \mathbb{I}) \).
\]
\[
P.2 \quad (\sigma, \tau) = (\sigma, \tau)_C \sigma(Z(A)) = \tau(Z(A)) \sigma(Z(A)) .
\]

2.26 Remark (i) The conditions P.1-P.2 imply that each basis of \( (\sigma, \tau)_C \) is simultaneously a module basis of \( (\sigma, \tau) \) modulo \( \sigma(Z(A)) \) as a right module, i.e. the module \( (\sigma, \tau) \) is free.

(ii) We will call the DR-subcategory \( T_C \) in Theorem 2.25 admissible. If “minimality” is omitted from the hypotheses of Theorem 2.25, then property P.1 remains valid, but not P.2. In this case \( T_C \) is a DR-subcategory only. A construction of an example with admissible subcategory can be found in [25].

The converse of Theorem 2.25 is also true, and states the main duality result cf. [3]:

2.27 Theorem Let \( T \) be a \( C^* \)-tensor category of unital endomorphisms of \( A \) and let \( T_C \) be an admissible \( (DR-) \)subcategory. Then there is a minimal and regular Hilbert extension \( \{F, G\} \) of \( A \) such that \( T \) is isomorphic to the category of all canonical endomorphisms of \( \{F, G\} \). Moreover, if \( T_C, T_C' \) are two admissible subcategories of \( T \), then the corresponding Hilbert extensions are \( A \)-module isomorphic iff \( T_C \) is equivalent to \( T_C' \) i.e. iff there is a map \( V \) from \( \text{Ob } T \) to the arrows such that:
\[
V_\lambda \in (\lambda, \lambda), \quad V_\lambda \text{ is unitary, and } V_{\lambda \sigma} = V_\lambda \times V_\sigma,
\]
\[
(\lambda, \sigma)_C = V_\sigma(\lambda, \sigma)_C V_\lambda^* \subset (\lambda, \sigma)
\]
and we have the following compatibility relations for the corresponding permutators $\epsilon$, $\epsilon'$ and conjugates $R_\lambda, R'_\lambda$:

$$
\epsilon'(\lambda, \sigma) = (V_\sigma \times V_\lambda) \cdot \epsilon(\lambda, \sigma) \cdot (V_\lambda \times V_\sigma)^* \\
R'_\lambda = V_{\lambda \circ \lambda} R_\lambda, \quad S'_\lambda = \epsilon'(\lambda, \lambda) R'_\lambda.
$$

Thus, in minimal and regular Hilbert systems there is an intrinsic characterization of the category of all canonical endomorphisms in terms of $\mathcal{A}$ only. Moreover, up to $\mathcal{A}$-module isomorphisms, there is a bijection between minimal and regular Hilbert extensions and C*-tensor categories $\mathcal{T}$ of unital endomorphisms of $\mathcal{A}$ with admissible subcategories.

Note that Theorem 2.27 is a generalization of the DR-theorem for the case of nontrivial centre $\mathcal{Z}(\mathcal{A}) \supset \mathbb{C} \mathbb{1}$, i.e. it contains the case of the DR-theorem, in that if $\mathcal{Z}(\mathcal{A}) = \mathbb{C} \mathbb{1}$ then $\mathcal{T}$ itself is admissible (hence a DR-category) and the corresponding Hilbert extensions have trivial relative commutant.

### 2.6 Hilbert systems with abelian groups

If $\mathcal{G}$ is abelian the preceding structure simplifies radically. Specifically, $\hat{\mathcal{G}}$ is a discrete abelian group (the character group), each $\mathcal{H}_\gamma, \gamma \in \hat{\mathcal{G}}$ is one-dimensional with a generating unitary $U_\gamma$, hence the canonical endomorphisms $\rho_{\mathcal{H}_\gamma}$ (denoted by $\rho_{\gamma}$) are in fact automorphisms, necessarily outer on $\mathcal{A}$. Since $\rho_{\gamma_1} \circ \rho_{\gamma_2} = \rho_{\gamma_1 \gamma_2}$ in this case the set $\Gamma$ of all canonical endomorphisms $\rho_{\mathcal{H}_\gamma}$ is a group with the property $\hat{\mathcal{G}} \cong \Gamma/\text{int} \mathcal{A}$. Hence it is not necessary to consider direct sums, i.e. Property B for $\mathcal{A}$ can be dropped.

In the case $\mathcal{Z}(\mathcal{A}) = \mathbb{C} \mathbb{1}$ the permutators $\epsilon$ (restricted to $\hat{\mathcal{G}} \times \hat{\mathcal{G}}$) are elements of the second cohomology group $H^2(\hat{\mathcal{G}})$ and

$$
U_{\gamma_1} \cdot U_{\gamma_2} = \omega(\gamma_1, \gamma_2) U_{\gamma_1 \circ \gamma_2},
$$

where

$$
\epsilon(\gamma_1, \gamma_2) = \frac{\omega(\gamma_1, \gamma_2)}{\omega(\gamma_2, \gamma_1)}
$$

and $\omega$ is a corresponding 2-cocycle. The field algebra $\mathcal{F}$ is just the $\omega$-twisted discrete crossed product of $\mathcal{A}$ with $\hat{\mathcal{G}}$ (see e.g. p.86 ff. [2] for details). For the case $\mathcal{Z}(\mathcal{A}) \supset \mathbb{C} \mathbb{1}$ see [22] (though the minimal case is not mentioned there).

### 3 Kinematics for Quantum Constraints.

In this section we give a brief summary of the method of imposing quantum constraints, developed by Grundling and Hurst [12, 10, 15]. There are quite a number of diverse quantum constraint methods available in the literature at various levels of rigour (cf. [18]). The one we use here is the most congenial from the point of view of C*-algebraic methods. Our starting point is:

#### 3.1 Definition A quantum system with constraints is a pair $(\mathcal{B}, \mathcal{C})$ where the system algebra $\mathcal{B}$ is a unital C*-algebra containing the constraint set $\mathcal{C} = \mathcal{C}^*$. A constraint condition on $(\mathcal{B}, \mathcal{C})$ consists of the selection of the physical state space by:

$$
\mathcal{S}_D := \left\{ \omega \in \mathcal{S}(\mathcal{B}) \mid \pi_\omega(C) \Omega_\omega = 0 \quad \forall C \in \mathcal{C} \right\},
$$

where $\mathcal{S}(\mathcal{B})$ denotes the state space of $\mathcal{B}$, and $(\pi_\omega, \mathcal{H}_\omega, \Omega_\omega)$ denotes the GNS-data of $\omega$. The elements of $\mathcal{S}_D$ are called Dirac states. The case of unitary constraints means that $\mathcal{C} = \mathcal{U} - \mathbb{1}$, $\mathcal{U} \subset \mathcal{B}_u$, and for this we will also use the notation $(\mathcal{B}, \mathcal{U})$. 

The assumption is that all physical information is contained in the pair \((B, \mathcal{S}_D)\). Examples of constraint theories as defined here, have been worked out in detail for various forms of electromagnetism cf. [12] [13] [15].

For the case of unitary constraints we have the following equivalent characterizations of the Dirac states (cf. [12] Theorem 2.19 (ii)):

\[
\mathcal{S}_D = \left\{ \omega \in \mathcal{S}(B) \mid \omega(U) = 1 \quad \forall U \in \mathcal{U} \right\}
\]

(5)

\[
= \left\{ \omega \in \mathcal{S}(B) \mid \omega(FU) = \omega(F) = \omega(UF) \quad \forall F \in B, U \in \mathcal{U} \right\}.
\]

(6)

Moreover, the set \(\{\alpha_U := \text{Ad}(U) \mid U \in \mathcal{U}\}\) of automorphisms of \(B\) leaves every Dirac state invariant, i.e. we have \(\omega \circ \alpha_U = \omega\) for all \(\omega \in \mathcal{S}_D, U \in \mathcal{U}\).

For a general constraint set \(C\), observe that we have:

\[
\mathcal{S}_D = \left\{ \omega \in \mathcal{S}(B) \mid C^*C = 0 \quad \forall C \in C \right\}
\]

\[
= \left\{ \omega \in \mathcal{S}(B) \mid C \subseteq N_\omega \right\} = N_\perp \cap \mathcal{S}(B).
\]

Here \(N_\omega := \{F \in B \mid \omega(F^*F) = 0\}\) is the left kernel of \(\omega\) and \(N := \cap \{N_\omega \mid \omega \in \mathcal{S}_D\}\), and \(N_\perp\) denotes the annihilator of \(N\) in the dual of \(B\). Now \(N = \text{clo-span}(BC)\) because every closed left ideal is the intersection of the left kernels which contains it (cf. 3.13.5 in [17]). Thus \(N\) is the left ideal generated by \(C\). Since \(C\) is selfadjoint and contained in \(N\) we conclude

\[
C \subset C^*(C) \subset N \cap N^* = \text{clo-span}(BC) \cap \text{clo-span}(CB),
\]

where \(C^*(\cdot)\) denotes the \(C^*\)-algebra in \(B\) generated by its argument. Then we have (cf. [15]):

3.2 Theorem For the Dirac states we have:

(i) \(\mathcal{S}_D \neq \emptyset\) iff \(1 \notin C^*(C)\) iff \(1 \notin N \cap N^* =: \mathcal{D}\).

(ii) \(\omega \in \mathcal{S}_D\) iff \(\pi_\omega(\mathcal{D})\Omega_\omega = 0\).

(iii) An extreme Dirac state is pure.

We will call a constraint set \(C\) first class if \(1 \notin C^*(C)\), and this is the nontriviality assumption which we henceforth make [14, Section 3].

Now define

\[
\mathcal{O} := \{F \in B \mid [F, D] := FD - DF \in \mathcal{D} \quad \forall D \in \mathcal{D}\}.
\]

Then \(\mathcal{O}\) is the \(C^*\)-algebraic analogue of Dirac’s observables (the weak commutant of the constraints) [16]. Then (cf. [15]):

3.3 Theorem With the preceding notation we have:

(i) \(\mathcal{D} = N \cap N^*\) is the unique maximal \(C^*\)-algebra in \(\bigcap \{\text{Ker } \omega \mid \omega \in \mathcal{S}_D\}\). Moreover \(\mathcal{D}\) is a hereditary \(C^*\)-subalgebra of \(B\).

(ii) \(\mathcal{O} = M_B(\mathcal{D}) := \{F \in B \mid FD \in \mathcal{D} \supset DF \quad \forall D \in \mathcal{D}\}\), i.e. it is the relative multiplier algebra of \(\mathcal{D}\) in \(B\).

(iii) \(\mathcal{O} = \{F \in B \mid [F, C] \subset \mathcal{D}\}\), hence \(C' \cap B \subseteq \mathcal{O}\).

(iv) \(\mathcal{D} = \text{clo-span}(\mathcal{O}C) = \text{clo-span}(C\mathcal{O})\).
For the case of unitary constraints, i.e. \( C = U - 1 \), we have \( U \subset O \) and \( O = \{ F \in B \mid \alpha_U(F) - F \in D \ \forall \ U \in U \} \) where \( \alpha_U := \text{Ad} U \).

Thus \( D \) is a closed two-sided ideal of \( O \) and it is proper when \( \mathcal{S}_D \neq \emptyset \) (which we assume here by \( 1 \notin \mathcal{C}'(C) \)). Since the traditional observables are \( \mathcal{C}' \cap B \), by (iii) we see that these are in \( O \). In general \( O \) can be much larger than \( \mathcal{C}' \cap B \).

Define the maximal C*-algebra of physical observables as

\[ \mathcal{R} := O / D. \]

The factoring procedure is the actual step of imposing constraints. This method of constructing \( \mathcal{R} \) from \((B, C)\) is called the T-procedure in [12], and it defines a map \( T \) from first class constraint pairs \((B, C)\) to unital C*-algebras by \( T(B, C) := \mathcal{R} = O / D \). We require that after the T-procedure all physical information is contained in the pair \((\mathcal{R}, \mathcal{S} (\mathcal{R}))\), where \( \mathcal{S} (\mathcal{R}) \) denotes the set of states on \( \mathcal{R} \). Now, it is possible that \( \mathcal{R} \) may not be simple [12, Section 2], and this would not be acceptable for a physical algebra. So, using physical arguments, one would in practice choose a C*-subalgebra \( O_c \subset O \) containing the traditional observables \( \mathcal{C}' \) such that

\[ \mathcal{R}_c := O_c / (D \cap O_c) \subset \mathcal{R}, \]

is simple. The following result justifies the choice of \( \mathcal{R} \) as the algebra of physical observables (cf. Theorem 2.20 in [12]):

**3.4 Theorem** There exists a \( \omega^* \)-continuous isometric bijection between the Dirac states on \( O \) and the states on \( \mathcal{R} \).

Insofar as the physics is now specified by \( \mathcal{R} \), this suggests that we call two constraint sets equivalent if they produce the same \( \mathcal{R} \). More precisely two constraint sets \( \mathcal{C}_1 \subset B \supset \mathcal{C}_2 \) are called equivalent, denoted \( \mathcal{C}_1 \sim \mathcal{C}_2 \), if they select the same set of Dirac states, cf. [15]. In fact

\[ \mathcal{C}_1 \sim \mathcal{C}_2 \ \text{iff} \ \text{clo-span}(BC_1) = \text{clo-span}(BC_2) \ \text{iff} \ D_1 = D_2. \]

The hereditary property of \( D \) can be further analyzed, and we list the main points (the proofs are in Appendix A of [15]).

Denote by \( \pi_u \) the universal representation of \( B \) on the universal Hilbert space \( \mathcal{H}_u \) [17, Section 3.7], \( B'' \) is the strong closure of \( \pi_u(B) \) and since \( \pi_u \) is faithful we make the usual identification of \( B \) with a subalgebra of \( B'' \), i.e. generally omit explicit indication of \( \pi_u \). If \( \omega \in \mathcal{S} (B) \), we will use the same symbol for the unique extension of \( \omega \) from \( B \) to \( B'' \).

**3.5 Theorem** For a constrained system \((B, C)\) there exists a projection \( P \in B'' \) such that

(i) \( N = B'' P \cap B \),

(ii) \( D = P B'' P \cap B \)

(iii) \( \mathcal{S}_D = \{ \omega \in \mathcal{S} (B) \mid \omega(P) = 0 \} \)

(iv) \( O = \{ A \in B \mid PA(1 - P) = 0 = (1 - P)AP \} = P' \cap B \).

A projection satisfying the conditions of Theorem 3.5 is called open in [17].

What this theorem means, is that with respect to the decomposition

\[ \mathcal{H}_u = P \mathcal{H}_u \oplus (1 - P) \mathcal{H}_u \]
we may rewrite
\[ \mathcal{D} = \left\{ F \in \mathcal{B} \mid F = \begin{pmatrix} D & 0 \\ 0 & 0 \end{pmatrix}, D \in \mathcal{P}_B \right\} \quad \text{and} \quad \mathcal{O} = \left\{ F \in \mathcal{B} \mid F = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}, A \in \mathcal{P}_B, B \in (1 - P)\mathcal{B}(1 - P) \right\}. \]

It is clear that in general \( \mathcal{O} \) can be much greater than the traditional observables \( \mathcal{C}' \cap \mathcal{B} \). Next we show how to identify the final algebra of physical observables \( \mathcal{R} \) with a subalgebra of \( \mathcal{B}' \).

3.6 Theorem For \( P \) as above we have:
\[ \mathcal{R} \cong \left\{ F \in \mathcal{B} \mid F = \begin{pmatrix} 0 & 0 \\ 0 & A \end{pmatrix} \right\} = (1 - P)(P' \cap \mathcal{B}) \subset \mathcal{B}''. \]

Below we will need to consider a constraint system contained in a larger algebra, specifically, \( \mathcal{C} \subset \mathcal{A} \subset \mathcal{F} \) where \( \mathcal{C} \) is a first-class constraint set, and \( \mathcal{A}, \mathcal{F} \) are unital C*-algebras. Now there are two constrained systems to consider: \((\mathcal{A}, \mathcal{C})\) and \((\mathcal{F}, \mathcal{C})\). The first one produces the algebras \( \mathcal{D} \subset \mathcal{O} \subset \mathcal{A} \), and the second produces \( \mathcal{D}_\mathcal{F} \subset \mathcal{O}_\mathcal{F} \subset \mathcal{F} \). where as usual,
\[ \mathcal{N} = \operatorname{clo}\-\operatorname{span}(\mathcal{A}\mathcal{C}), \quad \mathcal{D} = \mathcal{N} \cap \mathcal{N}^*, \quad \mathcal{O} = \mathcal{M}_\mathcal{A}(\mathcal{D}) \quad \text{and} \quad \mathcal{N}_\mathcal{F} = \operatorname{clo}\-\operatorname{span}(\mathcal{F}\mathcal{C}), \quad \mathcal{D}_\mathcal{F} = \mathcal{N}_\mathcal{F} \cap \mathcal{N}_\mathcal{F}^*, \quad \mathcal{O}_\mathcal{F} = \mathcal{M}_\mathcal{F}(\mathcal{D}_\mathcal{F}). \]

Then we have (cf. Theorem 3.2 of [10]):

3.7 Theorem Given as above \( \mathcal{C} \subset \mathcal{A} \subset \mathcal{F} \) then
\[ \mathcal{N}_\mathcal{F} \cap \mathcal{A} = \mathcal{N}, \quad \mathcal{D}_\mathcal{F} \cap \mathcal{A} = \mathcal{D}, \quad \text{and} \quad \mathcal{O}_\mathcal{F} \cap \mathcal{A} = \mathcal{O}. \]

Hence \( \mathcal{R} = \mathcal{O}/\mathcal{D} = (\mathcal{O}_\mathcal{F} \cap \mathcal{A})/(\mathcal{D}_\mathcal{F} \cap \mathcal{A}) \).

4 Superselection with constraints.

Next we would like to consider systems containing both constraints and superselection. There is a choice in how to define this problem mathematically, so let us consider the physical background. Perhaps the most important example, is that of a local gauge theory. It usually has a set of global charges (leading to superselection) as well as a Gauss law constraint (implementing the local gauge symmetry), and possibly also other constraints associated with the field equation.

Only if the gauge group is abelian will the Gauss law constraint commute with the global charge, since the Gauss law constraint takes its values in the Lie algebra of the gauge group. Thus, for nonabelian local gauge theories we do not expect the constraints to be in the algebra of gauge invariant observables \( \mathcal{A} \) of the superselection theory of the global charge. This problem is however not as serious as it looks. The reason is that whilst the global gauge group does not preserve the individual Gauss law constraints, it does preserve the set of these, hence it also preserves the set of Dirac states selected by them. Thus we can replace the original constraint set by an equivalent constraint (i.e. selecting the same set of Dirac states) which is invariant under the global gauge group. Such an equivalent constraint is given by the projection in Theorem 3.5.

It comes at the cost of slightly enlarging the system algebra \( \mathcal{B} \), since \( P \) is in the universal Von Neumann algebra of \( \mathcal{B} \). We can avoid this cost if \( \operatorname{clo}\-\operatorname{span}(\mathcal{C}) \) is separable, since then there is an equivalent constraint in \( \mathcal{B} \) itself, cf. Theorem 3.4 of [15].

We therefore will assume below that the constraints are in in \( \mathcal{A} \). This will include the situation where there are two or more local gauge symmetries which mutually commute (e.g.
isospin and electromagnetism), in which case the Gauss law constraint of one symmetry will commute with the global charges of the other. We can also easily find constraints which are independent of the gauge symmetries, e.g. restriction to a submanifold, or enforcing a dynamical law.

Let now \((A, C)\) be a first–class constraint system, hence we have the associated algebras \(D \subset O \subset A\), and \(R = O/D\). In addition, let \(A\) have a superselection structure i.e. there is a given Hilbert extension \(\{F, G\}\) of \(A\). Thus the category \(T\) of canonical endomorphisms of \(A\) defines a selection criterion of unital endomorphisms of \(A\). In the case that the Hilbert extension is minimal and regular, the superselection structure of \(T\) is given within \(A\) without any reference to the Hilbert extension.

Then the following natural questions arise:

(1) what compatibility conditions should be satisfied in order to pass the superselection structure through \(T\), thus obtaining a superselection structure on \(T(A, C) = R\)?

(2) what is the relation between \(T(A, C)\) and \(T(F, C)\) where \(F\) is the field algebra generated from \(T\)?

An inverse question also arises, i.e.

(3) if \(R\) has a superselection structure, what is the weakest structure one can expect on \(A\) which would produce this superselection structure on \(R\) via \(T\)? (One should call this a weak superselection structure.)

To address (1) and (2), recall that the map \(T\) consists of a restriction (of \(A\) to \(O\)) followed by a factoring \((O \rightarrow O/D)\). So, we first work out the compatibility conditions involved with restrictions and factoring maps.

Since \(C \subset A \subset F\), there are two constrained systems to consider:- \((A, C)\) and \((F, C)\). The first one produces the algebras \(D \subset O \subset A\), and the second produces \(D_F \subset O_F \subset F\) (cf. Theorem 3.7). Now since \(C \subset A\), the \(G\)-invariant part of \(F\), it follows that \(G\) preserves the set of Dirac states, hence \(G\) preserves both \(D_F\) and \(O_F\), i.e. \(gD_F = D_F\) and \(gO_F = O_F\) for all \(g \in G\).

We denote the restriction of \(G\) to \(O_F\) by \(\beta_g := g|_{O_F}\). The homomorphism \(\beta : G \ni g \mapsto \beta_g \in \text{Aut} \, O_F\) is not necessarily injective but \(\beta\) is again pointwise norm-continuous, hence \(\hat{G}/K\) is compact where \(K := \text{Ker} \, \beta\). The isomorphism \(\beta : \hat{G}/K \rightarrow \beta_g\) by \(\hat{beta}(gK) := \beta_g\) is also a topological one (cf. p.58 [23]). Note that \(\hat{G}/K = \{\gamma \in \hat{G} \mid \gamma(k) = 1 \, \text{ for all } k \in K\} \supseteq \text{spec} \beta_g\).

The spectral projections \(\Pi_{\gamma}^g\) of \(\beta_g\) are given by the restriction to \(O_F\) of the spectral projections \(\Pi_{\gamma}\) of \(G\), i.e. \(\Pi_{\gamma}^gX = \Pi_{\gamma}X\) for \(X \in O_F\).

We now have the:

(I) Restriction problem. Find conditions to guarantee that the \(C^*\)-dynamical system \(\{O_F, G, \beta\}\) is a Hilbert system \(\{O_F, \beta_g\}\). Thus we have to find conditions to ensure there are algebraic Hilbert spaces in \(\Pi_{\gamma}O_F\) for \(\gamma \in (\hat{G}/K)\). (Note that this is stronger than what we need:- we only need a Hilbert system on \(R_F\) after factoring out by \(D_F\).)

(II) Factoring problem. Find conditions to guarantee that under the map \(O_F \rightarrow R_F := O_F/D_F\) the factoring through of the action of \(G\) to \(R_F\) is a Hilbert system corresponding to a DR–category. This is of course a special case of the general problem for homomorphic images of Hilbert systems under factoring by invariant ideals. The reason why we require \(Z(A) = C \mathbb{1}\) for \(R_F\) is because after implementing constraints, the final physical algebra should be simple.

Below we list our major results;- since some proofs are lengthy, we defer these to Section 6 to preserve the main flow of ideas.
4.1 Restricting a superselection structure.

We consider now for the system above the restriction problem (I), i.e. we are given a Hilbert extension \( \{ \mathcal{F}, \mathcal{G} \} \) of \( \mathcal{A} \), containing constraints \( \mathcal{C} \subset \mathcal{A} \), and we need to examine when \( \{ \mathcal{O}_\mathcal{F}, \beta_\mathcal{G} \} \) is a Hilbert system.

**4.1 Theorem**

(i) \( \{ \mathcal{O}_\mathcal{F}, \mathcal{G}, \beta \} \) has fixed point algebra \( \mathcal{O} \). Moreover, \( Z(\mathcal{A}) \subseteq Z(\mathcal{O}) \).

(ii) For any \( \mathcal{G} \)-invariant algebraic Hilbert space \( \mathcal{H}_\gamma \subset \Pi_F \mathcal{F} \) we have either \( \mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} = \{0\} \), or \( \mathcal{H}_\gamma \subset \mathcal{O}_\mathcal{F} \). In the latter case we have \( \gamma \in \mathcal{G}/\mathcal{K} \) where \( \mathcal{K} = \text{Ker} \beta \), and

\[
\mathcal{H}_\gamma \subset \Pi_F \mathcal{O}_\mathcal{F} = \text{clo-span}(\mathcal{O}_\mathcal{H}_\gamma).
\]

(iii) Let \( \sigma \in \text{Ob} \mathcal{T} \), with \( \mathcal{H}_\sigma \subset \mathcal{F} \) a \( \mathcal{G} \)-invariant algebraic Hilbert space such that \( \sigma = \rho_{\mathcal{H}_\sigma} \).

If \( \mathcal{H}_\sigma \subset \mathcal{O}_\mathcal{F} \), then \( \sigma(\mathcal{D}) \subseteq \mathcal{D} \) and \( \sigma(\mathcal{O}) \subseteq \mathcal{O} \). Thus \( \sigma \) restricts to \( \mathcal{O} \), \( \sigma \uparrow \mathcal{O} \in \text{End} \mathcal{O} \).

The central condition for \( \{ \mathcal{O}_\mathcal{F}, \mathcal{G}, \beta \} \) to be a Hilbert system \( \{ \mathcal{O}_\mathcal{F}, \beta_\mathcal{G} \} \) w.r.t. the factor group \( \mathcal{G}/\mathcal{K} \) is \( \mathcal{H}_\gamma \subset \mathcal{O}_\mathcal{F} \), i.e. \( \mathcal{H}_\gamma \subset \Pi_F \mathcal{O}_\mathcal{F} \) for all \( \gamma \in \mathcal{G}/\mathcal{K} \).

Next, we develop an internal criterion on \( \mathcal{A} \) to guarantee that a given \( \mathcal{H} \in \text{Ob} \mathcal{T}_\mathcal{G} \) is contained in \( \mathcal{O}_\mathcal{F} \).

**4.2 Theorem**

(i) Given the Hilbert extension \( \{ \mathcal{F}, \mathcal{G} \} \) of the constrained system \( \mathcal{C} \subset \mathcal{A} \) assumed here, we have for any \( \mathcal{G} \)-invariant algebraic Hilbert space \( \mathcal{H} \) that

\[
\mathcal{H} \subset \mathcal{O}_\mathcal{F} \text{ iff } \mathcal{D} \sim \rho_\mathcal{H}(\mathcal{D})
\]

i.e.

\[
\mathcal{D} = \text{clo-span}(\mathcal{A}\rho_\mathcal{H}(\mathcal{D})) \cap \text{clo-span}(\rho_\mathcal{H}(\mathcal{D})\mathcal{A}).
\]

(ii) For all \( \sigma, \tau \in \text{Ob} \mathcal{T} \) with \( \mathcal{H}_\sigma, \mathcal{H}_\tau \subset \mathcal{O}_\mathcal{F} \) we have

\[
(\sigma, \tau)_\mathcal{A} \subseteq (\sigma \uparrow \mathcal{O}, \tau \uparrow \mathcal{O})_\mathcal{O}.
\]

Observe that \( \mathcal{D} \sim \rho_\mathcal{H}(\mathcal{D}) \) implies that \( \rho_\mathcal{H}(\mathcal{D}) \subseteq \mathcal{D} \).

**4.3 Corollary** We have that \( \{ \mathcal{O}_\mathcal{F}, \mathcal{G}/\mathcal{K}, \beta \} \) is a Hilbert system \( \{ \mathcal{O}_\mathcal{F}, \beta_\mathcal{G} \} \) w.r.t. \( \mathcal{G}/\mathcal{K} \) iff \( \mathcal{D} \sim \rho_\gamma(\mathcal{D}) \) holds for all \( \gamma \in \mathcal{G}/\mathcal{K} \). In particular, if \( \mathcal{D} \sim \rho_\gamma(\mathcal{D}) \) holds for all \( \gamma \in \mathcal{G} \) then \( \mathcal{G}/\mathcal{K} \cong \mathcal{G} \) i.e. \( \mathcal{K} \) is trivial.

Whilst the condition \( \mathcal{D} \sim \rho_\gamma(\mathcal{D}) \) is exact for \( \mathcal{H}_\gamma \subset \mathcal{O}_\mathcal{F} \), it may not be in practice that easy to verify. We therefore consider alternative conditions which will allow the main structures involved with Hilbert extensions to survive the restriction of \( \{ \mathcal{F}, \mathcal{G} \} \) to \( \{ \mathcal{O}_\mathcal{F}, \beta_\mathcal{G} \} \).

Recalling the definition of subobjects, introduce the notation \( E \simeq 1 (\text{mod } \mathcal{A}) \) for a projection \( E \in \mathcal{A} \) to mean that there is an isometry \( V \in \mathcal{A} \), \( V^*V = 1 \) such that \( VV^* = E \) (i.e. Murray–Von Neumann equivalence of \( E \) and \( 1 \)).

**4.4 Definition** We say the constraint set \( \mathcal{C} \subset \mathcal{A} \) is an \( \mathcal{E} \)-constraint set if for each projection \( E \in \mathcal{O} \) such that \( E \simeq 1 (\text{mod } \mathcal{A}) \), we have that \( E \simeq 1 (\text{mod } \mathcal{O}) \).

The \( \mathcal{E} \)-constraint condition will ensure the survival of decomposition relations of restrictable canonical endomorphisms:

**4.5 Proposition** Let \( \{ \mathcal{F}, \mathcal{G} \} \) be a Hilbert system and let \( \mathcal{C} \subset \mathcal{O} \) be an \( \mathcal{E} \)-constraint set, \( \sigma \in \text{Ob} \mathcal{T} \) and \( \mathcal{H}_\sigma \subset \mathcal{O}_\mathcal{F} \) a \( \mathcal{G} \)-invariant algebraic Hilbert space. Then
Recall that the second step in the enforcement of constraints is the factoring problem, first in a general context. Consider a Hilbert system with Property B and \( G \subset \text{Aut}(\mathcal{O}) \) such that every irreducible representation of \( G \) is contained in a tensor representation of \( \gamma_0 \). Let \( C \subset \mathcal{A} \) be an E–constraint set then \( \mathcal{H}_{\gamma_0} \subset \mathcal{O}_F \) implies that \( \{ \mathcal{O}_F, \beta_G \} \) is a Hilbert system.

Proof: This follows from Proposition 4.5 by making use of the obvious fact that \( \mathcal{H}_\tau \subset \mathcal{O}_F \subset \mathcal{H}_\sigma \) for \( \tau, \sigma \in \text{Ob} \mathcal{T} \).

If the group \( G \) is isomorphic to \( U(N) \) then it satisfies the condition of Theorem 4.6.

4.7 Proposition Let \( E \in \mathcal{O} \) with \( E \simeq \mathbb{I}(\mathbb{Z}) \), then the set of isometries

\[
\mathcal{V}_E := \{ V \in \mathcal{A} \mid VV^* = E, \quad V^*V = \mathbb{I} \}
\]

is nonempty. We have:

\[
\mathcal{U}_E := \{ U \in \mathcal{A} \mid U^*U = E = UU^* \}
\]

such that \( VPV^* = PU^* \).

4.2 Morphisms of general Hilbert systems.

Recall that the second step in the enforcement of constraints is the factoring \( \mathcal{O}_\mathcal{F} \rightarrow \mathcal{R}_\mathcal{F} := \mathcal{O}_\mathcal{F}/\mathcal{D}_\mathcal{F} \). We now consider problem (II), the factoring problem, first in a general context. Consider a morphism of C*-algebras \( \xi: \mathcal{F} \rightarrow \mathcal{L} = \xi(\mathcal{F}) \). This specifies the subgroup of automorphisms

\[
\text{Aut}_\xi \mathcal{F} := \{ \alpha \in \text{Aut} \mathcal{F} \mid \alpha(\text{Ker} \xi) \subseteq \text{Ker} \xi \}
\]

and a homomorphism \( \text{Aut}_\xi \mathcal{F} \rightarrow \text{Aut} \mathcal{L} \) by \( \alpha \rightarrow \alpha^\xi \) where \( \alpha^\xi(\xi(F)) := \xi(\alpha(F)) \) for all \( F \in \mathcal{F} \). Henceforth let \( \{ \mathcal{F}, \mathcal{G} \} \) be a Hilbert system with Property B and \( \mathcal{G} \subset \text{Aut}_\xi \mathcal{F} \). Our task will be to find the best conditions to ensure that \( \{ \mathcal{L}, \mathcal{G}^\xi \} \) is a Hilbert system associated with a category described in Theorem 4.5. We will denote the spectral projections of \( \mathcal{G} \) (resp. \( \mathcal{G}^\xi \)) by \( \Pi_x \) (resp. \( \Pi_x^\xi \)). (Recall that in the context of the T-procedure, we have that \( \mathcal{G} \) preserves \( \mathcal{D}_\mathcal{F} \) due to the invariance of the constraints under \( \mathcal{G} \). So the current analysis applies).
4.8 Theorem Given a Hilbert system \( \{ F, G \} \) and a unital morphism \( \xi : F \to L = \xi(F) \), such that \( G \subset \text{Aut}_F F \), then we have:

(i) \( \{ L, G^\xi \} \) is a Hilbert system and \( G \cong G^\xi \).

(ii) If \( H_\gamma \subset \Pi_\gamma F \) is an invariant algebraic Hilbert space for \( G \), then so is \( \xi(H_\gamma) \subset \Pi_\gamma L \) for \( G^\xi \).

(iii) Let \( N_\gamma \) be any orthonormal basis for \( \xi(H_\gamma) \), then \( \bigcup \{ N_\gamma \mid \gamma \in \hat{G} \} \) is a left module basis of \( \xi(F_{\text{fin}}) \) w.r.t. \( \xi(A) \), i.e. the “essential part” of \( \xi \) is its action on \( A \).

(iv) The fixed point algebra of \( L \) w.r.t. \( G^\xi \) is exactly \( \xi(A) \), and \( \xi(F_{\text{fin}}) = L_{\text{fin}} \).

(v) If \( \{ F, G \} \) has Property B, so does \( \{ L, G^\xi \} \).

Thus corresponding to the two Hilbert systems \( \{ F, G \} \) and \( \{ L, G^\xi \} \) we now have the two categories \( \mathcal{T} \) and \( \mathcal{T}^\xi \) respectively. Moreover:

4.9 Corollary Under the conditions of Theorem 4.8 we have that

(i) for any canonical endomorphism \( \lambda \in \text{Ob } \mathcal{T} \),

\[
\lambda(\ker \xi \cap A) \subseteq \ker \xi \cap A.
\]

Hence there is a well-defined map \( \lambda \in \text{Ob } \mathcal{T} \mapsto \lambda^\xi \in \text{Ob } \mathcal{T}^\xi \), given by \( \lambda^\xi(\xi(A)) := \xi(\lambda(A)) \) for all \( A \in \mathcal{A} \).

(ii) the map \( \lambda \in \text{Ob } \mathcal{T} \mapsto \lambda^\xi \in \text{Ob } \mathcal{T}^\xi \) is compatible with products, direct sums and subobjects. It also preserves unitary equivalence.

We have that \( (\text{Ob } \mathcal{T})^\xi \subseteq \text{Ob } \mathcal{T}^\xi \), and we now claim that up to unitary equivalence, we have in fact equality:

4.10 Theorem Under the conditions of Theorem 4.8 we have that

(i) if \( \sigma \in \text{Ob } \mathcal{T}^\xi \), then there is always a \( \lambda \in \text{Ob } \mathcal{T} \) such that \( \lambda^\xi \) is unitarily equivalent to \( \sigma \), i.e. each unitary equivalence class in \( \text{Ob } \mathcal{T}^\xi \) contains at least one element of the form \( \lambda^\xi \).

(ii) the map \( \lambda \in \text{Ob } \mathcal{T} \mapsto \lambda^\xi \in \text{Ob } \mathcal{T}^\xi \) produces an isomorphism between the sets of unitary equivalence classes of \( \text{Ob } \mathcal{T} \) and \( \text{Ob } \mathcal{T}^\xi \) which is compatible with products direct sums and subobjects.

The relation between the arrows of the two categories is however less direct:

4.11 Lemma Under the conditions of Theorem 4.8 we have

\[
\xi((\sigma, \tau)_A) \subseteq (\sigma^\xi, \tau^\xi)_{\xi(A)}.
\]

Next we show that \( \ker \xi \) is uniquely determined by \( \ker \xi \cap F_{\text{fin}} \).

4.12 Proposition Under the conditions of Theorem 4.8 we have that

(i) \( \ker \xi \cap F_{\text{fin}} = \text{Span } \{ (\ker \xi \cap A)H_\gamma \mid \gamma \in \hat{G} \} \),

(ii) \( \ker \xi = \text{clo}_{\text{A}} I (\ker \xi \cap F_{\text{fin}}) \cap F \).
Thus Ker$\xi$ is in fact uniquely determined by Ker$\xi \cap A$, as is already suggested by Theorem $4.8$(iii). Since $F$ is in general not complete w.r.t. $|\cdot|_A$, the intersection with $F$ in $4.12$(ii) is necessary.

Theorem $4.8$ suggests that we consider the following subcategory of $T^\xi$.

**4.13 Definition** The subcategory $\xi(T)$ of $T^\xi$ is defined by the objects

$$\text{Ob}\xi(T) := (\text{Ob} T)^\xi$$

and the arrows

$$(\sigma^\xi, \tau^\xi)_0 := \xi((\sigma, \tau)_A).$$

By Theorem $4.10$ the sets of all unitary equivalence classes of $\text{Ob}\xi(T)$ and $\text{Ob} T^\xi$ coincide, each equivalence class of $\text{Ob}\xi(T)$ is a subset of the corresponding equivalence class of $\text{Ob} T^\xi$, but in general these equivalence classes are much larger.

Lemma $4.11$ says that the arrow sets $((\sigma^\xi, \tau^\xi))_0$ of the objects of $\text{Ob}\xi(T)$ considered as objects of $\text{Ob} T^\xi$ are in general larger than the corresponding arrow sets in $\xi(T)$. The reason is that an element $X = \xi(Y), Y \in A$, belongs to $((\sigma^\xi, \tau^\xi))_0$ if $Y\sigma(A) - \tau(A)Y \in \text{Ker}\xi$ for all $A \in A$. The arrow sets coincide only if this relation already implies $Y\sigma(A) - \tau(A)Y = 0$.

**4.3 Morphisms of minimal and regular Hilbert systems**

Recall now that by Theorems $2.26$ and $2.27$ we have an equivalence between minimal and regular Hilbert systems with Property B and the endomorphism category $T$ with an admissible subcategory $T_C$. We called a subcategory $T_C$ admissible if it satisfies conditions P.1–P.2 in Theorem $2.25$.

As in the last subsection, we consider a unital morphism $\xi : F \to L = \xi(F)$, and recall by Proposition $4.12$ that $\xi$ is determined by its action on $A$. Now whilst it is obvious that $\xi(Z(A)) \subseteq Z(\xi(A))$, we require below the stronger condition:

$$\xi(Z(A)) = Z(\xi(A)) \tag{7}$$

When $\xi(A)$ is a simple C*-algebra (as we require for the final observables after a T–procedure), the condition (7) will be satisfied.

**4.14 Theorem** Given a minimal and regular Hilbert system $\{F, G\}$ with Property B, and a unital morphism $\xi : F \to L = \xi(F)$ such that $G \subseteq \text{Aut}_\xi F$ and condition (7) holds, then:

(i) there is a DR–subcategory $T_C^\xi$ of $\xi(T)$,

(ii) property P.2 is satisfied for $T_C^\xi$ iff $\xi(A)' \cap \xi(F) = \xi(Z(A))$. In this case the subcategory $T_C^\xi$ is admissible.

(iii) If $\xi(A)' \cap \xi(F) = \xi(Z(A))$, then

$$(\sigma^\xi, \tau^\xi)_{\xi(A)} = \xi((\sigma, \tau)_A)$$

for all $\sigma, \tau \in \text{Ob} T$, where we made use of the notation and result in Corollary $4.9$.

(iv) In this case choose $H_\gamma \in \text{Ob} T_G$. Then

$$\mathcal{M}^\xi := \{ \rho_{\xi(H_\gamma)} \mid \gamma \in \hat{G} \} \subseteq \text{Ob} \xi(T)$$

is a complete system of (irreducible) and mutually disjoint objects of $\text{Ob} \xi(T)$.
4.4 The inverse problem.

4.15 Theorem Let $A$ be a unital $C^*$-algebra with Property B, and let $T$ be a $C^*$-tensor category of unital endomorphisms of $A$. Let $T$ have an admissible subcategory $T_C$ whose arrow spaces are denoted by $(\sigma, \tau)_C$. Furthermore, let $\xi$ be a unital morphism of $A$ such that

1. $\xi(Z(A)) = Z(\xi(A))$,
2. $\lambda(Ker \xi) \subseteq Ker \xi$ for all $\lambda \in \text{Ob } T$. Thus we can define endomorphisms $\lambda^\xi \in \text{End } \xi(A)$ by $\lambda^\xi(\xi(A)) := \xi(\lambda(A))$ for all $A \in A$ and a category $\xi(T)$ with objects

$$\text{Ob } \xi(T) := \{ \lambda^\xi \mid \lambda \in \text{Ob } T \}$$

and arrows $(\sigma^\xi, \tau^\xi)_{\xi(A)}$, which is closed w.r.t. direct sums and products.

3. $\xi((\sigma, \tau)_A) = (\sigma^\xi, \tau^\xi)_{\xi(A)}$ for all $\sigma, \tau \in \text{Ob } T$.

Then there is a subcategory $T_C^\xi$ of $\xi(T)$ with $\text{Ob } T_C^\xi = \text{Ob } \xi(T)$ which is admissible for $\xi(T)$.

Thus by Theorem 2.27 there are Hilbert extensions $F$ and $F^\xi$ corresponding to $T$ and $\xi(T)$ respectively. Moreover, the Hilbert extension $F^\xi$ of $\xi(A)$ can be chosen in such a way that it is the homomorphic image of $F$ under a morphism which is an extension of $\xi$. That is, $F^\xi = \xi(F)$ where $\xi$ is a morphism of $F$ such that $\xi(A) = \xi(A)$ for all $A \in A$.

4.16 Remark A posteriori, the set of objects $\text{Ob } \xi(T)$ defined in (8) could be enlarged by filling up the unitary equivalence classes of each $\lambda^\xi$ by all $\tau$ with $\tau = \text{Ad } V \circ \xi(\lambda)$, where $V \in \xi(A)$ is unitary. This corresponds to the objects of the category $T_C^\xi$ of Definition 4.13. In this case we also have to add additional arrows, so if $\tau_i = \text{Ad } V_i \circ \xi(\lambda_i)$, $i = 1, 2$, then we also need

$$(\tau_1, \tau_2)_{\xi(A)} := V_2(\tau_1^\xi, \tau_2^\xi)_{\xi(A)} V_1^{-1}.$$

However, for the application of Theorem 2.27 this is not necessary.

4.5 Superselection structures left after constraining.

Recall that the enforcement of constraints by $T$–procedure produces a final physical algebra $R$. This algebra is usually assumed to be simple; if it is not, then the physics is not fully defined, and one should extend the constraint set $C \subset A$ to make $R$ simple (the choice of the extension needs to be physically motivated).

In the previous subsections we examined which conditions need to be satisfied by a Hilbert extension $\{F, G\}$ of $A$ for its structure to pass through the two parts of the $T$–procedure. Here we combine these to produce conditions on the initial system which will ensure that we obtain a Hilbert extension of $R$. We will also examine when this final Hilbert extension is regular (and this produces then a DR–category via simplicity of $R$).

4.17 Theorem Let $\{F, G\}$ be a Hilbert extension of $A$, and let $C \subset A$ be a first-class constraint set such that $D \sim \rho_\gamma(D)$ holds for all $\gamma \in G/K$. Then $\{R_F, \beta_G\}$ is a Hilbert extension of $R$, where $R_F = \xi(O_F)$, and $\xi$ is the factor map $O_F \rightarrow O_F/D_F$.

Proof: By Corollary 4.3 it follows from the hypotheses that $\{O_F, \beta_G\}$ is a Hilbert extension of $O$. Since the constraint set $C \subset A$ is $G$–invariant, we have that $\alpha(D_F) = D_F$ for all $\alpha \in \beta_G \subset \text{Aut } O_F$, i.e. $\beta_G \subset \text{Aut } O_F$. (Recall the discussion in the introductory part of Section 4). Thus by Theorem 4.8 it follows that $(\beta_G)^\xi \cong \beta_G$, and that

$$\{\xi(O_F), (\beta_G)^\xi\} = \{R_F, \beta_G\}$$
is a Hilbert extension of \( R = \xi(O) \).

Next, we would like to examine when a Hilbert extension as in Theorem 4.17 will produce a minimal and regular Hilbert extension of \( R \) (with Property B).

First recall the requirement for a Hilbert system \( \{F, G\} \) to be regular: there is an assignment \( \sigma \to H_\sigma \) from Ob \( T \) to \( G \)-invariant algebraic Hilbert spaces in \( F \) such that

(i) \( \sigma = \rho_{H_\sigma} \), i.e. \( \sigma \) is the canonical endomorphism of \( H_\sigma \),

(ii) \( \sigma \circ \tau \to H_\sigma \cdot H_\tau \),

that is, the assignment is compatible with products.

We now want to check whether this property also survives the map \( T : \{F, G\} \to \{R_F, \beta_G\} \).

4.18 Proposition Let \( T \) satisfy regularity. Let \( D \sim \rho_\gamma(D) \) for all \( \gamma \in \hat{G}/K \), then \( \{R_F, \beta_G\} \) satisfies regularity, i.e. there is an assignment \( \sigma \to H_\sigma \) such that 

(i) \( \sigma = \rho_{H_\sigma} \), i.e. \( \sigma \) is the canonical endomorphism of \( H_\sigma \),

(ii) \( \sigma \circ \tau \to H_\sigma \cdot H_\tau \).

Proof: Given the assignment \( \sigma \to H_\sigma \) in \( F \), then whenever \( \sigma = \rho_\gamma, \gamma \in \hat{G} \) we have

\[
\sigma \to H_\sigma \subset O_F \longrightarrow R_F
\]

where the last map is \( \xi \), so the assignment which we take for this proposition is \( \sigma \to \xi(H_\sigma) \). Then (i) and (ii) are automatic.

Second, we consider Property B.

4.19 Proposition Let \( \{O_F, \beta_G\} \) satisfy Property B, let \( G \) be nonabelian and \( C \subset A \) be an E-constraint set. If \( D \sim \rho_\gamma(D) \) for all \( \gamma \in \hat{G}/K \), then \( \{O_F, \beta_G\} \) satisfies Property B.

Proof: First \( \{O_F, \beta_G\} \) is a Hilbert extension of \( O \) w.r.t. \( G/K \) because of Corollary 4.3. Choose an \( \hat{G} \)-invariant Hilbert space \( \hat{H} \subset O_F \subset F \) which is not irreducible, i.e. there is a projection \( E \in \mathcal{F}(\hat{L}_G(H)) \), \( 0 < E < 1 \). Then one has \( E \in (\rho_H, \rho_H)_A \subset (\rho_H|O, \rho_H|O) \subset O \) by Theorem 4.2(ii). By Property B we get closure under subobjects, so there is a \( V \in A, V^*V = 1, VV^* = E \). In other words, \( E \cong 1 \pmod{A} \). Similarly we obtain \( 1 - E \equiv 1 \pmod{A} \). Since \( C \) is an E-constraint set and \( E \in O \) we get that \( E \equiv 1 \pmod{O} \) and \( 1 - E \equiv 1 \pmod{O} \) and this is the assertion.

Finally, we need to consider whether the requirement

\[
A' \cap \mathcal{F} = Z(A)
\]

passes through the T-procedure. In full generality, this is a very hard problem, because both stages of the T-procedure can eliminate or create elements of \( A' \). In fact, since \( A' \cap \mathcal{F} \subset D \cap \mathcal{F} \subset O_F \) and \( Z(A) \subset Z(O) \), we can only deduce from \( A' \cap \mathcal{F} = Z(A) \) that \( \xi(A' \cap \mathcal{F}) = \xi(Z(A)) \). On the other hand, \( \mathcal{R}' \cap \mathcal{R}_F = Z(\mathcal{R}) \) iff

\[
A \in O_F \quad \text{and} \quad [A, O] \subset D_F \quad \text{implies} \quad A \in O + D_F
\]

which can be true in general for more elements than those in \( \xi(A' \cap \mathcal{F}) \).

We do have from Theorem 4.2 and Proposition 2.22 the following condition:

4.20 Proposition Let \( \{F, G\} \) be a minimal Hilbert extension of \( A \), and let \( C \subset A \) be a first-class constraint set such that \( D \sim \rho_\gamma(D) \) holds for all \( \gamma \in \hat{G}/K \). If the disjointness of canonical endomorphisms survives the restriction to \( O \) then the Hilbert system \( \{O_F, \beta_G\} \) is minimal, i.e. \( O' \cap O_F = Z(O) \).
5 Example

It is difficult to produce interesting worked examples in the current state of the theory. The problem is that in almost all theories of physical significance, the canonical endomorphisms $\rho_\gamma$ are not known explicitly, and so one cannot check the compatibility conditions with the constraints explicitly (cf. Corollary 4.3). Here we give an example which is extracted from QED, so it may have some physical interest. It consists of a fermion in an Abelian gauge potential. Since the global gauge group $\mathcal{G}$ is abelian, the superselection theory simplifies radically. However, we have explicit endomorphisms $\rho_\gamma$ and can check the compatibility conditions with the constraints. Nevertheless, even at this simple level, it is not possible to verify all the conditions of regularity. We will not treat the issue of dynamics.

5.1 Constraint structure of QED

We start with a discussion of the set-up of QED in order to motivate our subsequent example. The starting point for QED, is a fermion field $\psi$ in $\mathbb{R}^4$ satisfying the free CARs, and a $U(1)$-gauge potential $A$ in $\mathbb{R}^4$ satisfying free CCRs, and initially these are assumed to commute. So the appropriate C*-algebraic framework at this initial level is

$$B := \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)$$

where $\mathcal{H} = L^2(\mathbb{R}^4, \mathbb{C}^4)$, $S = S(\mathbb{R}^4, \mathbb{R}^4)/\text{Ker } B$, and $B$ denotes the symplectic form for QEM, coming from the Jordan–Wigner distribution, cf. Sect 5 of [15]. (Note that the tensor product $B$ is unique because CAR($\mathcal{H}$) is a nuclear algebra.) There is a global charge $Q$ acting on CAR($\mathcal{H}$) and there are constraints in the heuristic theory:

$$A_\mu :^\mu(x) := 0 \quad (\text{Lorentz condition})$$

and $\Box A_\mu := j_\mu \quad (\text{Maxwell equation})$

where $j_\mu := -e\bar{\psi}\gamma_\mu \psi$ is the electron current, and we denote $\bar{\psi} := \psi^* \gamma_0$. The Lorentz condition has been treated in the C*-algebra context (cf. [15]) and it needs special treatment, e.g. indefinite metric or nonregular states, but it is not very interesting for us, since it only affects the electromagnetic field CCR($S, B$), hence is independent of the charge $Q$. The Maxwell equation is more interesting, since it involves both factors of $B$ and it expresses the interaction between the two fields. It is however very difficult to enforce in the C*-algebra context (and ultimately leads to the conclusion that $B$ is too small an algebra to do this in). Naively, it seems that we can easily realise both sides of the Maxwell equation in the present C*-setting: smear the left-hand side over $S(\mathbb{R}^4, \mathbb{R}^4)$

$$\int \Box A_\mu(x) f^\mu(x) \, dx = \int A_\mu \Box f^\mu \, dx = A(\Box f)$$

then this is realised in CCR($S, B$) through the identification of the generating Weyl unitaries $\delta_h$ with the heuristic exp $iA(h)$ where $h = \Box f$. If we smear the right-hand side of the Maxwell equation:

$$j(f) = -e \int \bar{\psi}(x)\gamma_\mu \psi(x) f^\mu(x) \, dx ,$$

then $j(f)$ generates a Bogoliubov transformation $T_f$ on $L^2(\mathbb{R}^4, \mathbb{C}^4)$ by:

$$\text{Ad} \left( \exp i j(f) \right) \psi(g) := \left( \exp i \text{ad} j(f) \right) (\psi(g))$$

$$= \psi(T_f g) =: \alpha_{T_f}(\psi(g))$$
where $\alpha_{T_f}$ is its associated automorphism on $\text{CAR}(\mathcal{H})$ (we will calculate $T_f$ explicitly in a simplified setting below). Let $G \subset \text{Aut} \mathcal{B}$ be the discrete group generated in $\text{Aut} \mathcal{B}$ by

$$\{ \beta_f := \alpha_{T_f} \otimes t \mid f \in \mathcal{S}(\mathbb{R}^4, \mathbb{R}^4) \}$$

and let $\nu$ denote its action on $\mathcal{B}$. Define the crossed product

$$\mathcal{E} := G \times_{\nu} \mathcal{B} = C^* \left\{ \mathcal{B}, U_g \mid U_g^* = U_g^{-1}, \nu_g = \text{Ad} U_g, U_g U_h = U_{gh}, g, h \in G \right\}$$

then we identify the heuristic objects $\exp ij(f)$ with the implementing unitaries $U_{\beta_f}$. So each side of the Maxwell equation has a C*-realisation, and we only need to decide how to impose the constraint equation. Heuristically, the Maxwell equations are imposed as state conditions: $A(\Box f)\phi = j(f)\phi$ for vectors $\phi$ in the representing Hilbert (or Krein) space. If we take instead the stronger condition $A(\Box f)^n \phi = j(f)^n \phi$ for $n \in \mathbb{N}$, then we can rewrite the constraint conditions in the form $e^{IA(\Box f)}\phi = e^{Sj(f)}\phi$. This suggests that we choose constraint unitaries $V_f := U_{-\beta_f} \cdot \delta_{\Box f}$ in $\mathcal{E}$ and thus select our Dirac states $\omega$ on $\mathcal{E}$ by

$$\omega(V_f) = 1 \quad \forall f \in \mathcal{S}(\mathbb{R}^4, \mathbb{R}^4).$$

As one expects from the interaction, this program encounters problems:

1. We always have that $\Box f \in \text{Ker} B$, hence $\Box f$ corresponds to zero in $\mathcal{S}$ (since we factor out by $\text{Ker} B$). This can be remedied by changing $\mathcal{S}$ to $\mathcal{S}(\mathbb{R}^4, \mathbb{R}^4)$, in which case $(\mathcal{S}, B)$ is a degenerate symplectic space. This problem is connected to the fact that the heuristic smearing formula

$$A(f) = \int_{\mathbb{R}^4} \left( a_\mu(p) \hat{f}_\mu(p) + a_\mu^+(p) \hat{f}_\mu^+(p) \right) \frac{dp}{p_0}$$

cannot be correct for the interacting theory, since it implies that $A(\Box f) = 0$, in contradiction with the Maxwell equation.

2. Interaction mixes the fermions and bosons, so it is unrealistic to expect that the interacting fermion and boson fields will commute (as in the tensor product structure of $\mathcal{B}$). Even worse, perturbation theory suggests that the interacting fields need not be canonical, so the assumption of the CCR and CAR relations for the interacting bosons and fermions is problematic.

### 5.2 Model for the interacting Maxwell constraint

Inspired by the observations above, we now propose an example which is a simplified version of the Maxwell constraint. Heuristically, we want to impose a constraint of the form

$$a^*(x) a(x) = L A(x)$$

where $a(x)$ is a fermion field on $\mathbb{R}^4$, $A$ is a boson field and $L$ is a linear differential operator on $\mathcal{S}(\mathbb{R}^4)$. To realise this, together with a superselection structure in a suitable C*-algebra setting, we present our construction in six steps.

**STEP 1.**

For the fermion field, let $\mathcal{H} = L^2(\mathbb{R}^4)$ and define $\text{CAR}(\mathcal{H})$ in Araki’s self-dual form (cf. [1]) as follows. On $\mathcal{K} := \mathcal{H} \oplus \mathcal{H}$ define an antiunitary involution $\Gamma$ by $\Gamma(h_1 \oplus h_2) := \overline{h}_2 \oplus \overline{h}_1$. Then $\text{CAR}(\mathcal{H})$ is the unique simple C*-algebra with generators $\{ \Phi(k) \mid k \in \mathcal{K} \}$ such that $k \rightarrow \Phi(k)$ is antilinear, $\Phi(k)^* = \Phi(\Gamma k)$, and

$$\{ \Phi(k_1), \Phi(k_2)^* \} = (k_1, k_2) \mathbb{1}, \quad k_i \in \mathcal{K}.$$
The correspondence with the heuristic creators and annihilators of fermions is given by \( \Phi(h_1 \oplus h_2) = a(h_1) + a^*(h_2) \), where

\[
a(h) = \int a(x) h(x) \, d^4x, \quad a^*(h) = \int a^*(x) h(x) \, d^4x.
\]

STEP 2.
For the boson field, let \( S = S(\mathbb{R}^4, \mathbb{R}) \), and let \( K : S \to L^2(M, \mu) \) be a linear map, where \((M, \mu)\) is a fixed measure space. Define a symplectic form on \( S \) by \( B(f, g) := \text{Im}(Kf, Kg) \), where \((\cdot, \cdot)\) is the inner product of \( L^2(M, \mu) \). Note that \( B \) is degenerate if \( \text{Ker} \, K \) is nonzero. Define then \( \text{CCR}(S, B) = C^* \{ \delta_f \mid f \in S \} \) where the \( \delta_f \) are unitaries satisfying the Weyl relations:

\[
\delta_f \cdot \delta_g = \delta_{f+g} \exp[iB(f, g)/2]
\]

i.e. \( \text{CCR}(S, B) \) is the \( \sigma \)-twisted discrete group algebra of \( S \) w.r.t. the two–cocale \( \sigma(f, g) := \exp[iB(f, g)/2] \).

STEP 3.
To combine the bosons and fermions in one \( C^* \)-algebra, we want to allow for the possibility that they may not commute with each other, hence we will not take the tensor algebra \( \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B) \). However, we don’t know what form their commutators should take, so we start with the free \( C^* \)-algebra \( \mathcal{E} \) generated by \( \text{CAR}(\mathcal{H}) \) and \( \text{CCR}(S, B) \). The free \( C^* \)-algebra \( \mathcal{E} \) seems to be big enough to allow for possible interactions, but it is also likely to contain redundant elements.

To be explicit, let \( L \) be the linear space spanned by all monomials of the form \( A_0B_0A_1B_1 \cdots A_nB_n \) where \( A_i \in \text{CAR}(\mathcal{H}) \) and \( B_i \in \text{CCR}(S, B) \). Note that \( L \) is an algebra w.r.t. concatenation. Factor out by the ideal generated by \( 1_{\text{CAR}} - 1_{\text{CCR}} \) and replace concatenation by multiplication for any two elements in a monomial which are in the same algebra (either \( \text{CAR} \) or \( \text{CCR} \)) after the factorisation. Note that this will now produce all possible monomials of elements in \( \text{CAR}(\mathcal{H}) \) and \( \text{CCR}(S, B) \) - just consider those monomials in \( L \) with \( A_0 \) or \( B_n \) the identity to obtain all other monomials. Now the resultant algebra \( \mathcal{N} \) is a \(*\)-algebra with the involution given by

\[
(A_0B_0 \cdots A_nB_n)^* = B_n^*A_n^* \cdots B_0^*A_0^*.
\]

Form the enveloping \( C^* \)-algebra \( \mathcal{E} \) of \( \mathcal{N} \), i.e. let

\[
\mathcal{I}_0 := \bigcap \{ \text{Ker} \, \pi \mid \pi \in \text{Hilbert space representations of } \mathcal{N} \}
\]

and set \( \mathcal{E} := \overline{\mathcal{N}/\mathcal{I}_0} \) where the closure is w.r.t. the enveloping \( C^* \)–norm, i.e.

\[
\|A\| := \sup \{ \|\pi(A)\| \mid \pi \in \text{Hilbert space representations of } \mathcal{N} \}.
\]

That \( \mathcal{E} \) is nontrivial, follows from the fact that any tensor product representation of \( \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B) \) defines a Hilbert space representation of \( \mathcal{N} \), hence it follows that \( \mathcal{E} \) is nonzero and that \( \text{CAR}(\mathcal{H}) \) and \( \text{CCR}(S, B) \) are faithfully embedded in \( \mathcal{E} \) (as the images under the factorisation maps of the original generating algebras in the construction). Note that we have a surjective homomorphism \( \zeta : \mathcal{E} \to \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B) \) given by

\[
\zeta(A_0B_0 \cdots A_nB_n) := (A_0 \cdots A_n) \otimes (B_0 \cdots B_n), \quad A_i \in \text{CAR}(\mathcal{H}), \; B_i \in \text{CCR}(S, B).
\]

Clearly the ideal \( \mathcal{I}_F \) of \( \mathcal{E} \) generated by the commutators \([\text{CAR}(\mathcal{H}), \text{CCR}(S, B)]\) is in \( \text{Ker} \, \zeta \). Since \( \mathcal{E} \) probably contains redundant elements, we do not require it to be simple. \( \zeta \) will be
important in proofs below.

STEP 4.

Next, we would like to model in the current C*-setting, the global and local heuristic charges:

\[ Q = \int a^*(x) a(x) \, d^4x, \quad Q(f) = \int a^*(x) a(x) f(x) \, d^4x, \quad f \in \mathcal{S}(\mathbb{R}^4, \mathbb{R}). \]

Let us calculate the Bogoliubov transformations which they induce:

\[
[Q(f), \Phi(h_1 \oplus h_2)] \\
= \int \int \left[ a^*(x)a(x) f(x), a(y)\overline{h_1(y)} + a^*(y)\overline{h_2(y)} \right] \, d^4x \, d^4y \\
= \int \int f(x) \left\{ (a^*(x)a(x)y - a(y)a^*(x)a(x))\overline{h_1(y)} \\
+ (a^*(x)a(x)a^*(y) - a^*(y)a^*(x)a(x))\overline{h_2(y)} \right\} \, d^4x \, d^4y \\
= \int \int f(x) \left\{ - \{a^*(x), a(y)\}a(x)\overline{h_1(y)} \\
- (a^*(x)\delta(x-y) - a^*(y)a(x)) - a^*(y)a^*(x)a(x)\overline{h_2(y)} \right\} \, d^4x \, d^4y \\
= -a(\overline{f} \cdot h_1) + a^*(f \cdot \overline{h_2}) \\
= \Phi(-\overline{f} \cdot h_1 + \overline{f} : f \cdot h_2) = \Phi(f(-h_1 \oplus h_2))
\]

since \( f \) is real. For the global charge \( Q \), just put \( f = 1 \) in the last calculation. Thus

\[
(\text{ad } Q(f))^n(\Phi(h_1 \oplus h_2)) = \Phi(f^n \cdot ((-1)^n h_1 \oplus h_2)) \quad \text{hence:}
\]

\[
(\text{Ad } \exp i Q(f))(\Phi(h_1 \oplus h_2)) = \left( \exp i \text{ ad } Q(f) \right)(\Phi(h_1 \oplus h_2)) \\
= \sum_{n=0}^{\infty} \frac{(i \text{ ad } Q(f))^n}{n!} (\Phi(h_1 \oplus h_2)) \\
= \sum_{n=0}^{\infty} \frac{i^n}{n!} \Phi(f^n((-1)^n h_1 \oplus h_2)) \\
= \Phi(e^{-if} h_1 \oplus e^{if} h_2) =: \Phi(T_f(h_1 \oplus h_2)).
\]

Now \( T_f \) is unitary on \( \mathcal{K} \), and satisfies \( [T_f, \Gamma] = 0 \) hence it is a Bogoliubov transformation (cf. p43 in [1]), and so we can define automorphisms on \( \text{CAR}(\mathcal{H}) \) by

\[
\tilde{\gamma}_f(\Phi(k)) := \Phi(T_f k) .
\]

It is clear that \( T_f T_g = T_{f+g} \), hence that \( \tilde{\gamma} : \mathcal{S}(\mathbb{R}^4) + \mathbb{R} \to \text{Aut}(\text{CAR}(\mathcal{H})) \) is a homomorphism. We extend these automorphisms to maps \( \gamma_f \) on \( \mathcal{E} \) by setting

\[
\gamma_f |_{\text{CAR}(\mathcal{H})} = \tilde{\gamma}_f , \quad \text{and} \quad \gamma_f |_{\text{CCR}(S,B)} = \iota
\]

where \( \iota \) is the identity map. The only relations between \( \text{CAR}(\mathcal{H}) \) and \( \text{CCR}(S,B) \) in the free construction of \( \mathcal{E} \), is \( \mathbb{1}_{\text{CAR}} = \mathbb{1}_{\text{CCR}} \), so since the definition of \( \gamma_f \) preserves this relation, it will
extend to a well-defined map on the free *-algebra *N*. In fact, since γ*f replaces CAR(H) by an isomorphic one in a free construction, it will be an automorphism on *N*, and so will define an automorphism on the enveloping algebra *E*.

Let *G* denote the Abelian group generated in Aut *E* by {γ*f | f ∈ S(ℝ⁴) ∪ ℝ} and equip it with the discrete topology. Denote its action by β: *G* → Aut *E*, and define the algebra

\[ A := G \times _{\beta} E, \]

then we identify the implementing unitaries *U*γ*f ∈ *A* of γ*f ∈ Aut *E* with the heuristic objects \( \exp iQ(f) \)ψ = A(Lf)ψ ∀ f ∈ S(ℝ⁴), n ∈ ℕ

where L: S → Ker K ⊆ Ker B is a given linear map. First write the heuristic constraints in bounded form:

\[ e^{iQ(f)} \psi = e^{iA(Lf)} \psi, \quad \text{i.e.} \quad e^{-iA(Lf)} e^{iQ(f)} \psi = \psi. \]

So, given the identifications with heuristic objects above, we define our constraint unitaries to be:

\[ \mathcal{U} := \left\{ \delta_{-L_f} \cdot U_{\gamma f} =: V_f \mid f \in S(\mathbb{R}^4, \mathbb{R}) \right\} \subset A. \]

5.1 Proposition \( \mathcal{U} \) is first–class.

The proof is in the next section. The heuristic constraint conditions now correspond to the application of the T–procedure to \( \mathcal{U} \).

STEP 6.

Now we will specify the superselection structure associated with the global charge Q using the fact that Q must take integer values on the vacuum state. Recall that the global gauge transformations γ*t, t ∈ ℝ are implemented by the unitaries *U*γ*t ∈ *A* which we identify with the heuristic objects \( \exp itQ \) (cf. Step 3). For the superselection sectors we need to find cyclic representations \((\pi, \Omega)\) such that

\[ \pi(U_{\gamma t})\Omega = e^{itn}\Omega \quad \forall t \in \mathbb{R} \]

and some \( n \in \mathbb{Z} \) (the heuristic corresponding conditions are \( Q\Omega = n\Omega \)). We recognise these as constraint conditions for Dirac states of the constraint unitaries:

\[ \mathcal{V}_n := \left\{ V_t^{(n)} := e^{-itn}U_{\gamma t} \mid t \in \mathbb{R} \right\}. \]

Denote the sets of these Dirac states by

\[ \mathcal{G}_D^{(n)} := \left\{ \omega \in \mathcal{G}(\mathcal{A}) \mid \omega(V_t^{(n)}) = 1 \quad \forall t \in \mathbb{R} \right\}. \]

These folia of states will be our superselection sectors.

5.2 Lemma With notation as above, we have:
\( (i) \; \mathcal{G}^{(n)}_D \cap \mathcal{G}^{(m)}_D = \emptyset \) if \( n \neq m \),

\( (ii) \; \mathcal{G}^{(0)}_D \neq \emptyset \).

**Proof:** (i) If there is an \( \omega \in \mathcal{G}^{(n)}_D \cap \mathcal{G}^{(m)}_D \) for \( n \neq m \), then

\[
\omega(e^{-itn}U_{\gamma_t}) = 1 = \omega(e^{-itm}U_{\gamma_t})
\]

so:

\[
\omega(U_{\gamma_t}) = e^{itn} = e^{itm} \; \forall \; t
\]

which contradicts \( n \neq m \).

(ii) In the proof of Lemma 5.1 we constructed a state \( \omega_3 \in \mathfrak{S}(A) \) satisfying \( \omega_3(U_g) = 1 \) for all \( g \in G \). If we take \( g = \gamma_t \), then this implies that \( \omega_3 \in \mathcal{G}^{(0)}_D \). \hfill \blacksquare

To connect with the usual machinery for superselection used above, we need to exhibit the canonical endomorphisms (automorphisms in the abelian case). We construct an action \( \rho : \mathbb{Z} \rightarrow \text{Aut} \mathfrak{A} \) such that its dual action on \( \mathfrak{A}^\ast \) satisfies \( \rho^\ast_k(\mathcal{G}^{(n)}_D) = \mathcal{G}^{(n+k)}_D \).

**5.3 Definition** For each \( k \in \mathbb{Z} \) define a \( \ast \)-automorphism \( \rho_k \) of \( \mathfrak{A} \) by:

\[
\rho_k(A) = A \; \forall \; A \in \mathcal{E}; \quad \rho_k(U_{\gamma_t}) = e^{ik}U_{\gamma_t} \; \forall \; t \in \mathbb{R}; \quad \rho_k(U_{\gamma_f}) = U_{\gamma_f} \; \forall \; f \in \mathcal{S}(\mathbb{R}^4).
\]

**5.4 Lemma** \( \rho_k \) is well-defined, and \( \rho_k \in \text{Aut} \mathfrak{A} \).

The proof is in the next section. Recall that for any \( \alpha \in \text{Aut} \mathfrak{A} \) we define its dual \( \alpha^\ast : \mathfrak{A}^\ast \rightarrow \mathfrak{A}^\ast \) by \( \alpha^\ast(f) := f \circ \alpha \) for all functionals \( f \in \mathfrak{A}^\ast \).

**5.5 Proposition** With notation as above, we have \( \rho^\ast_k(\mathcal{G}^{(n)}_D) = \mathcal{G}^{(n+k)}_D \) and \( \mathcal{G}^{(n)}_D \neq \emptyset \) for all \( n \in \mathbb{Z} \).

**Proof:** Let \( \omega \in \rho^\ast_k(\mathcal{G}^{(n)}_D) \), i.e. \( \omega = \omega_n \circ \rho_k \) for some \( \omega_n \in \mathcal{G}^{(n)}_D \). Thus

\[
\omega\left(e^{-it(n+k)}U_{\gamma_t}\right) = \omega_n\left(e^{-it(n+k)}\rho_k(U_{\gamma_t})\right) = \omega_n\left(e^{-itn}U_{\gamma_t}\right) = 1
\]

i.e. \( \omega \in \mathcal{G}^{(n+k)}_D \). Conversely, for any \( \omega \in \mathcal{G}^{(n+k)}_D \) there is an \( \omega_n \in \mathcal{G}^{(n)}_D \) for which \( \omega = \omega_n \circ \rho_k \) and it is obviously \( \omega_n = \omega \circ \rho_{-k} \). Thus \( \rho^\ast_k(\mathcal{G}^{(n)}_D) = \mathcal{G}^{(n+k)}_D \). Since we have that \( \mathcal{G}^{(0)}_D \neq \emptyset \), it is now immediate that \( \mathcal{G}^{(n)}_D = \rho^\ast_k(\mathcal{G}^{(0)}_D) \neq \emptyset \). \hfill \blacksquare

Recall from our earlier discussions that the canonical automorphisms (Abelian case) must necessarily be outer on \( \mathfrak{A} \).

**5.6 Proposition** With notation as above, \( \rho_k \in \text{Out} \mathfrak{A} \) if \( k \neq 0 \).

The proof of this is long, and is in the next section.

From the action \( \rho : \mathbb{Z} \rightarrow \text{Out} \mathfrak{A} \) we construct a Hilbert extension (cf. Subsection 2.6). First set

\[
\Lambda := \{ \text{Ad} \; U \circ \rho_k \mid U \in \mathfrak{A} \text{ unitary}, \; k \in \mathbb{Z} \}
\]

so \( \mathbb{Z} = \Lambda/\text{Inn} \mathfrak{A} \). So the class of \( k \in \mathbb{Z} \) in \( \Lambda/\text{Inn} \mathfrak{A} \) is \( \chi_k := \{ \text{Ad} \; U \circ \rho_k \mid U \in \mathbb{A}_0 \} \). Take the monomorphic section \( \chi_k \rightarrow k \), then it has a trivial cocycle \( \sigma(n, m) = 1 \) for all \( n, m \in \mathbb{Z} \). Define \( \mathcal{F} := \mathbb{Z} \times \mathfrak{A} \), then it has the dense \( \ast \)-algebra

\[
\mathcal{F}_0 := \left\{ \sum_{n \in F} A_n U^n \mid A_n \in \mathfrak{A}, \; F \subset \mathbb{Z} \text{ finite} \right\}
\]
where \( U \in \mathcal{F} \) is the unitary which implements \( \rho_1 \), i.e. \( \rho_1 = \text{Ad} U \upharpoonright \mathcal{A} \). Fix \( t \in \mathbb{T} = \hat{\mathbb{Z}} \) and define an action \( \alpha : \mathbb{T} \rightarrow \text{Aut} \mathcal{F} \) by

\[
\alpha_t \left( \sum_{n \in \mathcal{F}} A_n U^n \right) := \sum_{n \in \mathcal{F}} A_n t^n U^n \quad \text{on } \mathcal{F}_0.
\]

Then the fixed point algebra of \( \alpha \) is \( \mathcal{A} \). We verify the compatibility condition in Corollary 5.3.

5.7 Proposition \( \rho_k(\mathcal{D}) \sim \mathcal{D} \) for all \( k \in \mathbb{Z} \).

Proof: The constraint unitaries from which we define \( \mathcal{D} \) are \( V_f := \delta_{-Lf} \cdot U_{\gamma f} \), \( f \in \mathcal{S}(\mathbb{R}^4) \).

By definition \( 5.3 \) we have \( \rho_k(\mathcal{D}) \sim \mathcal{D} \). For \( k \in \mathbb{Z} \).

(ii) Now let \( \mathcal{H}_\gamma \subset \Pi, \mathcal{F} \). If there is a unit vector \( \Phi \in \mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} \), then by invariance of \( \mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} \) under \( \mathcal{G} \), we also have \( \mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} \supset \text{span}(\mathcal{G}\Phi) = \mathcal{H}_{\gamma} \), where the last equality follows from irreducibility of the action of \( \mathcal{G} \) on \( \mathcal{H}_\gamma \). Thus \( \mathcal{H}_\gamma \cap \mathcal{O}_\mathcal{F} \neq \{0\} \) implies that \( \mathcal{H}_\gamma \subset \mathcal{O}_\mathcal{F} \), hence \( \mathcal{H}_\gamma \subset \Pi \mathcal{O}_\mathcal{F} \).

To prove that \( \Pi \mathcal{O}_\mathcal{F} = \text{clo-span}(\mathcal{O}\mathcal{H}_\gamma) \) we follow the proof of Lemma 10.1.3 in [5]. First, since \( \mathcal{O} = \Pi \mathcal{O}_\mathcal{F} \), it follows that \( \mathcal{O}\mathcal{H}_\gamma \subseteq \Pi \mathcal{O}_\mathcal{F} \). By Evans and Sund [8], \( \Pi \mathcal{O}_\mathcal{F} \) is the closed span of all the \( \mathcal{G} \)-invariant subspaces \( \mathcal{E} \subset \mathcal{O}_\mathcal{F} \) such that \( \beta_\mathcal{G} \) acts on \( \mathcal{E} \) as an element of \( \gamma \in \mathcal{G}/\mathcal{K} \). For the reverse inclusion, \( \Pi \mathcal{O}_\mathcal{F} \subseteq \text{clo-span}\{\mathcal{O}\mathcal{H}_\gamma\} \), it suffices to show that \( \text{span}\{\mathcal{O}\mathcal{H}_\gamma\} \) contains all \( \mathcal{G} \)-invariant subspaces \( \mathcal{E} \subset \mathcal{O}_\mathcal{F} \) such that \( \mathcal{G} \) acts on \( \mathcal{E} \) as an element of \( \gamma \).

Let \( \{\Psi_1, \ldots, \Psi_d\} \), \( d = \dim \gamma \) be a basis of such an \( \mathcal{E} \) under which the matrix representation of the action of \( \mathcal{G} \) is an element of \( \gamma \), i.e.

\[
g \Psi_i = \sum_j \lambda_{ji}(g) \Psi_j
\]

where the matrix \( (\lambda_{ji}(g)) \) is a unitary matrix representation of \( \mathcal{G} \) of the type \( \gamma \). Choose an orthonormal basis \( \{\Phi_1, \ldots, \Phi_d\} \) of \( \mathcal{H}_\gamma \) which also transforms under \( \mathcal{G} \) according to \( (\lambda_{ji}(g)) \).

Consider now the element \( A := \sum j \Psi_j \Phi_j^* \in \mathcal{O}_\mathcal{F} \). Then

\[
g(A) = \sum j \left( \sum \lambda_{ij}(g) \lambda_{kj}(g) \right) \Psi_i \Phi_k^* = \sum_{i,k} \delta_{ik} \Psi_i \Phi_k^* = \sum j \Psi_j \Phi_j^* = A.
\]
Thus $A \in \mathcal{O}$, and hence all $\Psi_i = A \Phi_i \in \mathcal{OH}_\gamma$ i.e. $\mathcal{E} \subseteq \text{span}(\mathcal{OH}_\gamma)$.

(iii) Let $\mathcal{H}_\sigma$ have an orthonormal basis $\{\Phi_1, \ldots, \Phi_d\}$ hence $\rho_\sigma(F) = \sum_{j=1}^d \Phi_j F \Phi_j^*$ for $F \in \mathcal{F}$, $\rho_\sigma|_A = \sigma$. Since $\{\Phi_j\} \subset \mathcal{O}_\mathcal{F} = M(\mathcal{D}_\mathcal{F})$ it is clear that $\rho_\sigma$ preserves both $\mathcal{D}_\mathcal{F}$ and $\mathcal{O}_\mathcal{F}$. Since $\rho_\sigma$ also preserves $A$, it preserves $\mathcal{D} = \mathcal{D}_\mathcal{F} \cap A$ and $\mathcal{O} = \mathcal{O}_\mathcal{F} \cap A$, where these equalities come from Theorem 3.7.

**Proof of Theorem 4.2**

(i) Let $\mathcal{H} \subset \mathcal{O}_\mathcal{F}$ have an orthonormal basis $\{\Phi_j\}$. By the same proof as for Theorem 4.1, we have that $\rho_\mathcal{H}(\mathcal{D}) \subseteq \mathcal{D}$.

Since $\mathcal{O}_\mathcal{F}$ is a *-algebra and the relative multiplier algebra of $\mathcal{D}_\mathcal{F} \supseteq \mathcal{D}$, we have that

$$[\Phi_j^*, \mathcal{D}] \in \mathcal{D}_\mathcal{F} \quad \text{for all } D \in \mathcal{D}, \ j.$$

Thus:

$$\Phi_j^*[\Phi_j^*, D] \in \Phi_j \mathcal{D}_\mathcal{F} = \rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \Phi_j \subset \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \mathcal{F})$$

i.e.

$$D - \rho_\mathcal{H}(D) = \sum_j (\Phi_j^* \Phi_j D - \Phi_j D \Phi_j^*) \in \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \mathcal{F}).$$

So $D \in \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \mathcal{F})$ for all $D \in \mathcal{D}$.

Thus we have shown that $\mathcal{D} \subset \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \mathcal{F})$, and now we would like to show that $\text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \mathcal{F}) = \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F})$. We have that

$$\text{clo-span}(\mathcal{O}_\mathcal{F}) = \text{clo-span}(\mathcal{D}_\mathcal{F}) = \text{clo-span}(\mathcal{D}_\mathcal{F} \mathcal{F}),$$

so if we apply $\rho_\mathcal{H}$ to both sides of the last equation, multiply by $\mathcal{F}$ on the right and take closed span, we get:

$$\text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \rho_\mathcal{H}(\mathcal{F}) \mathcal{F}) = \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}_\mathcal{F}) \rho_\mathcal{H}(\mathcal{F}) \mathcal{F})$$

i.e.

$$\text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F}) = \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F}).$$

Thus:

$$\mathcal{D} \subset \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F})$$

and since $\mathcal{D}$ is a *-algebra in $\mathcal{A}$,

$$\mathcal{D} \subseteq \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F}) \cap \text{clo-span}(\mathcal{F} \rho_\mathcal{H}(\mathcal{D})) \cap \mathcal{A}$$

$$\subseteq \text{clo-span}(\mathcal{D}_\mathcal{F}) \cap \text{clo-span}(\mathcal{F}_\mathcal{D}) \cap \mathcal{A} = \mathcal{D}$$

where we used $\mathcal{D}_\mathcal{F} \cap \mathcal{A} = \mathcal{D}$. Thus

$$\mathcal{D} = \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F}) \cap \text{clo-span}(\mathcal{F} \rho_\mathcal{H}(\mathcal{D})) \cap \mathcal{A} = \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{A}) \cap \text{clo-span}(\mathcal{A} \rho_\mathcal{H}(\mathcal{D}))$$

which also follows from Theorem 3.7, treating $\rho_\mathcal{H}(\mathcal{D}) \subseteq \mathcal{D}$ as a second constraint set. Thus $\mathcal{D} \sim \rho_\mathcal{H}(\mathcal{D})$ in $\mathcal{A}$.

For the converse, let $\mathcal{D} \sim \rho_\mathcal{H}(\mathcal{D})$ and take $\Phi \in \mathcal{H}$. From the equation $\Phi \mathcal{D} = \rho_\mathcal{H}(\mathcal{D}) \Phi$ for all $D \in \mathcal{D}$, we conclude that

$$\Phi \cdot \text{clo-span}(\mathcal{D}_\mathcal{F}) \subset \text{clo-span}(\rho_\mathcal{H}(\mathcal{D}) \mathcal{F}) = \text{clo-span}(\mathcal{D}_\mathcal{F})$$

using $\mathcal{D} \sim \rho_\mathcal{H}(\mathcal{D})$. Since we have trivially that $\Phi \cdot \text{clo-span}(\mathcal{F}_\mathcal{D}) \subset \text{clo-span}(\mathcal{F}_\mathcal{D})$, it follows that

$$\Phi \mathcal{D}_\mathcal{F} = \Phi (\text{clo-span}(\mathcal{F}_\mathcal{D}) \cap \text{clo-span}(\mathcal{D}_\mathcal{F})) \subset \mathcal{D}_\mathcal{F}$$

so $\Phi$ is in the left multiplier of $\mathcal{D}_\mathcal{F}$. We also have that

$$\text{clo-span}(\mathcal{F}_\mathcal{D}) \Phi = \text{clo-span}(\mathcal{F} \rho_\mathcal{H}(\mathcal{D})) \Phi = \text{clo-span}(\mathcal{F} \Phi \mathcal{D}) \subseteq \text{clo-span}(\mathcal{F}_\mathcal{D})$$.
Since trivially $\text{clo-span}(DF)\Phi \subseteq \text{clo-span}(DF)$, it follows that

$$DF\Phi = (\text{clo-span}(FD) \cap \text{clo-span}(DF)) \Phi \subset DF$$

and hence $\Phi$ is in the relative multiplier algebra of $DF$, i.e. $\Phi \in \mathcal{O}_F$ by Theorem 3.3(ii).

(ii) Let $\mathcal{H}_\sigma \subset \mathcal{O}_F \subset \mathcal{H}_\tau$, hence by (i) $D \sim \sigma(D) \sim \tau(D)$.

First let $X \in (\sigma, \tau)_A \cap \mathcal{O}$, i.e. $X \in \mathcal{O}$ and $X\sigma(A) = \tau(A)X$ for all $A \in \mathcal{A}$. By letting $A$ range over only $\mathcal{O} \subset \mathcal{A}$, we immediately get that $X \in (\sigma\upharpoonright\mathcal{O}, \tau\upharpoonright\mathcal{O})_{\mathcal{O}}$, making use of Theorem 4.1(iii). Therefore, it suffices to prove that $(\sigma, \tau)_A \subset \mathcal{O}$.

Let $X \in (\sigma, \tau)_A$, i.e. $X \in A$ and $X\sigma(A) = \tau(A)X$ for all $A \in \mathcal{A}$. Thus

$$X \cdot \text{clo-span}(DA) = X \cdot \text{clo-span}(\sigma(D)A) = \text{clo-span}(X\sigma(D)A) \subseteq \text{clo-span}(\tau(D)X.A) \subseteq \text{clo-span}(\tau(D)A) = \text{clo-span}(DA).$$

Since we have trivially that $X \cdot \text{clo-span}(AD) \subseteq \text{clo-span}(AD)$, it follows that

$$XD \subseteq \text{clo-span}(AD) \cap \text{clo-span}(DA) = D,$$

i.e. $X$ is in the left multiplier of $D$. Likewise:

$$\text{clo-span}(AD) \cdot X = \text{clo-span}(A\tau(D)) \cdot X = \text{clo-span}(A\tau(D)X) \subseteq \text{clo-span}(AX\sigma(D)) \subseteq \text{clo-span}(A\sigma(D)) = \text{clo-span}(AD).$$

Since trivially $\text{clo-span}(DA) \cdot X \subseteq \text{clo-span}(DA)$, we have:

$$D \cdot X \subseteq \text{clo-span}(AD) \cap \text{clo-span}(DA) = D,$$

and hence $X$ is in the relative multiplier of $D$, i.e. $X \in \mathcal{O}$.

**Proof of Proposition 4.5**

(i) According to the decomposition

$$\sigma(\cdot) = \sum_j V_j \rho_{\gamma_j} (\cdot)V_j^*, \quad V_j \in (\rho_{\gamma_j}, \sigma)_A$$

we have $\mathcal{H}_\sigma = \sum_j V_j \mathcal{K}_j'$ where $\rho_{\gamma_j} = \rho_{\mathcal{K}_j'}$ and the $\mathcal{K}_j'$ are irreducible w.r.t. $\mathcal{G}$ carrying the representation $\gamma_j \in \hat{\mathcal{G}}$. Moreover $\text{supp} \mathcal{K}_j' = 1$.

Put $E_j := V_j V_j^*$. Then $\sum_j E_j = 1$. Since $V_j \mathcal{K}_j' \subset \mathcal{H}_\sigma \subset \mathcal{O}_F$ it follows that

$$E_j = \text{supp} V_j \mathcal{K}_j' \in \mathcal{O}$$

for all $j$. Therefore, by assumption, there are isometries $W_j \in \mathcal{O}$ with $E_j = W_j W_j^*$. Now we put

$$\mathcal{K}_j := W_j^* V_j \mathcal{K}_j' \subset \mathcal{O}_F.$$ 

Then $\mathcal{K}_j$ is an algebraic Hilbert space with $\text{supp} \mathcal{K}_j = 1$, carrying the representation $\gamma_j$ and we have $V_j \mathcal{K}_j' = W_j \mathcal{K}_j$. Hence $\mathcal{H}_\sigma = \sum_j W_j \mathcal{K}_j$ and

$$\sigma(\cdot) = \sum_j W_j \rho_{\mathcal{K}_j}(\cdot) W_j^*, \quad W_j \in (\rho_{\mathcal{K}_j}, \sigma)_A$$

follows.

(ii) This follows from (i) using the existence of subobjects.
Proof of Theorem 4.8

Let $\mathcal{H} \subset \mathcal{F}$ be an arbitrary algebraic Hilbert space. Then $\xi(\mathcal{H}) \subset \mathcal{L}$ is also an algebraic Hilbert space with support 1. To see this, let $\{\Phi_j\}_j$ be an orthonormal basis of $\mathcal{H}$, i.e. $\Phi_j^*\Phi_k = \delta_{j,k}1$ and $\sum_j \Phi_j\Phi_j^* = 1$ then the same relations are true for the system $\{\xi(\Phi_j)\}_j$. In particular $\xi$ is injective on $\mathcal{H}$. Moreover, if $\mathcal{H}$ is $\mathcal{G}$-invariant and $g(\Phi_j) = \sum_k u_{k,j}(g)\Phi_k$ then $g^*(\xi(\Phi_j)) = \sum_k u_{k,j}(g)\xi(\Phi_k)$, i.e. $\xi(\mathcal{H})$ carries the same representation as $\mathcal{H}$. In particular, if $\mathcal{H}_\gamma$ carries $\gamma$, i.e. $\mathcal{H}_\gamma \subset \Pi_\gamma \mathcal{F}$ then $\xi(\mathcal{H}_\gamma) \subset \Pi_\gamma \mathcal{L}$. This proves (ii) and (i).

Let $\mathcal{N}_\gamma$ be an orthonormal basis for $\xi(\mathcal{H}_\gamma)$, then by the first part it is the image under $\xi$ of an orthonormal basis $\{\Phi_{\gamma,j}\}_j$ of $\mathcal{H}_\gamma$. Let $F = \sum A_{\gamma,j}\Phi_{\gamma,j} \in \mathcal{F}_\text{fin}$ such that $\xi(F) = 0 = \sum \xi(A_{\gamma,j})\xi(\Phi_{\gamma,j})$. By applying $\mathcal{G}^\xi$ to this equality, and using the relation $g^*(\xi(\Phi_{\gamma,j})) = \sum u_{k,j}(g)\xi(\Phi_{\gamma,k})$ we get $\sum u_{k,j}(g)\xi(A_{\gamma,j})\xi(\Phi_{\gamma,k}) = 0$ for all $g \in \mathcal{G}$. Now the orthogonality relations for the matrix elements of the irreducible representations of $\mathcal{G}$ imply $\xi(A_{\gamma,j})\xi(\Phi_{\gamma,k}) = 0$ for all $\gamma \in \mathcal{G}, j, k$. Hence $\xi(A_{\gamma,j}) = 0$ follows. This proves (iii). From $\xi \circ \Pi_\gamma = \Pi_\gamma^\xi \circ \xi$ (iv) follows.

For (v) observe that the homomorphic images of isometries $V_i \in \mathcal{A}$ with $V_iV_i^* + V_2V_2^* = 1$ produces a pair of isometries in $\xi(\mathcal{A})$ satisfying the same relation. So Property B for $\mathcal{A}$ implies Property B for $\xi(\mathcal{A})$.

Proof of Corollary 4.9

(i) Let $\lambda$ be generated by $\mathcal{H}$, i.e. let $\lambda = \rho_\mathcal{H}$ such that $\lambda(A) = \sum_j \Phi_j A\Phi_j^*$ where $\{\Phi_j\}_j$ is an orthonormal basis of $\mathcal{H}$. Then $\xi(\lambda(A)) = \sum_j \xi(\Phi_j)\xi(A)\xi(\Phi_j)^*$ and $\xi(A) = 0$ implies $\xi(\lambda(A)) = 0$. Furthermore, $\lambda^\xi(\xi(A)) = \rho_\mathcal{H}(\lambda)\xi(A)$.

(ii) $\lambda(\cdot) = \sum_j W_j \lambda_j(\cdot) W_j^*$ implies $\lambda^\xi(\cdot) = \sum_j \xi(W_j)\lambda_j^\xi(\cdot)\xi(W_j)^*$ and $(\lambda \circ \sigma)^\xi = \lambda^\xi \circ \sigma^\xi$. Further, if $\sigma(\cdot) = V^*\lambda(\cdot)V$ where $V \in (\sigma, \lambda)$, i.e. $V \sigma(\cdot) = \lambda(\cdot)$ then $\xi(V)\sigma^\xi(\cdot) = \lambda^\xi(\cdot)\xi(V)$ and $\sigma^\xi(\cdot) = \lambda^\xi(\cdot)\lambda^\xi(V)$. In particular, if $\lambda \simeq \sigma$ then $\lambda^\xi \simeq \sigma^\xi$.

Proof of Theorem 4.10

(i) Let $\sigma \in \text{Ob} \mathcal{T}^\xi$. Then there is a $\mathcal{G}$-invariant algebraic Hilbert space $\mathcal{H} \subset \mathcal{L}$ such that $\sigma(X) = \sum_j \Psi_j X \Psi_j^*$, $X \in \xi(\mathcal{A})$, where $\{\Psi_j\}_j$ denotes an orthonormal basis of $\mathcal{H}$. On the other hand, there is a corresponding $\mathcal{G}$-invariant Hilbert space $\mathcal{K} \subset \mathcal{F}$ such that $\mathcal{H}$ and $\mathcal{K}$ carry unitarily equivalent representations of $\mathcal{G}$. In $\mathcal{K}$ we choose an orthonormal basis $\{\Phi_j\}_j$ such that the representation matrix of $\mathcal{G}$ in $\mathcal{H}$ w.r.t. $\{\Psi_j\}_j$ coincides with that in $\mathcal{K}$ w.r.t. $\{\Phi_j\}_j$. Then $\xi(\mathcal{K})$ transforms under $\mathcal{G}$ w.r.t. $\{\Phi_j\}_j$ with the same representation matrix. Now we put $V := \sum_j \Psi_j \xi(\Phi_j)^* \in \mathcal{L}$.

Obviously, $V$ is unitary and $g^\xi(V) = V$ for all $g \in \mathcal{G}$, i.e. $V \in \xi(\mathcal{A})$. Then $V \xi(\Phi_j) = \Psi_j$ or $\mathcal{H} = V \xi(\mathcal{K})$ and $\sigma = \text{Ad} V \circ \rho_\mathcal{K}^\xi$.

(ii) According to Corollary 4.9 and $(\text{Ob} \mathcal{T})^\xi \subseteq \text{Ob} \mathcal{T}^\xi$ the image $\mathcal{C}^\xi$ of an equivalence class $\mathcal{C} \subset \text{Ob} \mathcal{T}$ is contained in a unique equivalence class of $\text{Ob} \mathcal{T}^\xi$. But (i) says that every equivalence class $\mathcal{E}$ of $\text{Ob} \mathcal{T}^\xi$ is an image $\mathcal{E} = \mathcal{C}^\xi$.

Proof of Lemma 4.11

Let $A \in (\sigma, \tau)_\mathcal{A}$, then it follows immediately from $A \sigma(B) = \tau(B)A$, $B \in \mathcal{A}$ that $\xi(\mathcal{A}) \sigma^\xi(\xi(B)) = \tau^\xi(\xi(B))\xi(\mathcal{A})$ for all $B \in \mathcal{A}$. Recall that $\xi(\mathcal{A})$ is the fixed point algebra.
of \( g^\xi \).

**Proof of Proposition 4.12**

(i) This is obvious because the union \( \bigcup_\gamma N_\gamma \) of orthonormal bases \( N_\gamma \) of \( H_\gamma \) is an \( A \)-left module basis of \( F_{\text{fin}} \).

(ii) By a straightforward calculation one obtains for all \( F \in F \) that:

\[
(\xi(F),\xi(F))_{\xi(A)} = \xi((F,F)_A)
\]

and

\[
|\xi(F)|_{\xi(A)} = \|\xi((F,F)_A)\|^{1/2} \leq \|F,F\|_A = |F|_A,
\]

i.e. \( \xi \) is continuous w.r.t. the norm \( |\cdot|_A \). Now let \( F \in \text{clo}_{|\cdot|_A}(\ker \xi \cap F_{\text{fin}}) \), hence there is a sequence \( \{F_n\} \subset \ker \xi \cap F_{\text{fin}} \) such that \( |F_n - F|_A \to 0 \). Then \( \xi(F) = 0 \) follows. Conversely, let \( F \in \ker \xi \). Recall \( \xi \circ \Pi_\gamma = \Pi_\xi \circ \xi \) which implies \( \Pi_\xi F \in \ker \xi \). Now, according to Remark 2.5 (iv) we have \( F = \sum_\gamma \Pi_\gamma F \) w.r.t. the \( |\cdot|_A \)-norm convergence. This implies

\[
F \in \text{clo}_{|\cdot|_A}(\ker \xi \cap F_{\text{fin}}).
\]

**Proof of Theorem 4.14**

(i) Since \( \{F,G\} \) is minimal and regular, there exists an assignment \( \sigma \to H_\sigma \) such that an admissible (DR-)subcategory \( T_C \) can be defined by

\[
(\sigma,\tau)_A \subset (H_\sigma,H_\tau),
\]

cf. Theorem 2.25. Now we use the morphism \( \xi \) to define a corresponding subcategory \( T_C^\xi \) for \( \xi(T) \). Recall \( \text{Ob} \xi(T) = (\text{Ob} T)^\xi \subset \text{Ob} T^\xi \). We put

\[
\text{Ob} T_C^\xi := \text{Ob} \xi(T).
\]

Let \( \lambda,\sigma \in \text{Ob} T \). Then \( \lambda^\xi,\sigma^\xi \in \text{Ob} \xi(T) \) and the arrows are defined by

\[
(\sigma^\xi,\tau^\xi)_{\xi(A),C} := \xi((\sigma,\tau)_A)_C = \xi((H_\sigma,H_\tau)).
\]

Then

\[
(\xi^\xi,\iota^\xi)_{\xi(A),C} = \xi((\iota,\iota)_A)_C = \xi(C \mathbb{1}) = C\xi( \mathbb{1} ) = \mathbb{1}.
\]

It is straightforward to show that \( T_C^\xi \) has direct sums and subobjects (in the latter case note that if \( F \) is a nontrivial projection from \( (\sigma^\xi,\sigma^\xi)_{\xi(A),C} \) then there is a nontrivial projection \( E \in (\sigma,\sigma)_A \) such that \( F = \xi(E) \) because the \( (G^\xi \text{-invariant}) \) matrix \( \{p_{j,k}\}_{j,k} \) of \( F \) w.r.t. \( \{\xi(\Phi_{\sigma,j})\}_{j} \), where the \( \Phi_{\sigma,j} \) form an orthonormal basis of \( H_\sigma \), can be used to define a corresponding \( E \) in \( (\sigma,\sigma)_A \). Furthermore, the permutation and conjugation structures of \( T_C \) survive the morphism \( \xi \). Thus \( T_C^\xi \) is a DR-category. We use the notation \( T_C^\xi = \xi(T_C) \). (This result means: The Hilbert system \( \{\xi(F),G\} \) is regular.)

(ii) First let \( \xi(A) \cap \xi(F) = \xi(Z(A)) \). Then, according to Theorem 2.25 property P.2 can be fulfilled by an appropriate subcategory of the form described before. Second, let property P.2 be satisfied. Then \( \xi(T_C) \) is an admissible (DR-)subcategory of \( \xi(T) \). Therefore, according to Theorem 2.27 there is a corresponding minimal and regular Hilbert extension \( \tilde{F} \) of \( \xi(A) \). The uniqueness part of Theorem 2.27 gives that \( \tilde{F} \) and \( \xi(F) \) are \( A \)-module isomorphic, hence \( \xi(A) \cap \xi(F) = Z(\xi(A)) \) is also true.

(iii) The inclusion \( \supseteq \) is obvious (see Lemma 2.11). The assertion is

\[
(\sigma^\xi,\tau^\xi)_{\xi(A)} \subset \xi((\sigma,\tau)_A).
\]
First we prove this inclusion for the admissible subcategory, i.e. we assert
\[(\sigma^\xi, \tau^\xi)_{\xi(A),C} \subseteq \xi((\sigma, \tau)_A).\]

This is obvious by
\[(\sigma^\xi, \tau^\xi)_{\xi(A),C} = \xi((\sigma, \tau)_C) \subseteq \xi((\sigma, \tau)_A).\]

Second, recall that \(\xi((\sigma, \tau)_A)\) is a right module w.r.t. \(\sigma^\xi(\xi(Z(A)))\) and a left module w.r.t. \(\tau^\xi(\xi(Z(A)))\). On the other hand, \((\sigma^\xi, \tau^\xi)_{\xi(A)}\) is a right module w.r.t. \(\sigma^\xi(\xi(Z(A)))\) and a left module w.r.t. \(\tau^\xi(\xi(Z(A)))\). Further, according to P.2. \((\sigma^\xi, \tau^\xi)_{\xi(A),C}\) is a generating subset for this module. Since, by assumption, \(Z(\xi(A))\) and \(\xi(Z(A))\) coincide, the inclusion (9) follows.

(iv) This follows directly from \(\xi(A)' \cap \xi(F) = Z(\xi(A))\) and the fact that the unitary equivalence classes of \(T^\xi\) and \(\xi(T)\) coincide.

**Proof of Theorem 4.15**

Since \(T_C\) is an admissible (DR-)subcategory of \(T\) we can apply Theorem 2.27 i.e. there is a corresponding minimal and regular Hilbert extension \(\{F, G\}\) of \(A\). Therefore the arrows of the category \(T_C\) are given by
\[(\sigma, \tau)_{A,C} = (H_\sigma, H_\tau),\] where the Hilbert spaces \(H_\sigma, H_\tau\) generate the endomorphisms \(\sigma, \tau\) respectively.

Now it is not hard to show that the morphism \(\xi\) can be extended to a morphism of \(F\) by putting
\[\xi(\Phi_{\lambda,j}) := \Phi_{\lambda,j}\] (11)
where \(\lambda\) runs through a complete system of irreducible and mutually disjoint endomorphisms and \(\{\Phi_{\lambda,j}\}\) denotes an orthonormal basis of the Hilbert space \(H_\lambda\) which generates \(\lambda\) (recall and use Proposition 4.12). This morphism satisfies the assumptions of Theorem 4.8. The corresponding Hilbert system is denoted by \(\{F^\xi, G\}\) (recall that \(G^\xi \cong G\)). Equations (10) and (11) imply
\[\sigma^\xi(\xi(A)) = \sum_j \Phi_{\lambda,j}\xi(A)\Phi_{\lambda,j}^*\] and \(\xi((\sigma, \tau)_{A,C}) = (\sigma, \tau)_{A,C}\).

By assumption (iii) we have \(\xi((\sigma, \tau)_A) = (\sigma^\xi, \tau^\xi)_{\xi(A)}\). Since \((\sigma, \tau)_{A,C} \subseteq (\sigma, \tau)_A\) we have \(\xi((\sigma, \tau)_{A,C}) \subseteq (\sigma^\xi, \tau^\xi)_{\xi(A)}\). Therefore the subcategory \(T^\xi_C\) of \(\xi(T)\) defined by
\[(\sigma^\xi, \tau^\xi)_{\xi(A),C} := \xi((\sigma, \tau)_{A,C}) = (\sigma, \tau)_{A,C}\]
is a DR-category.

Now we prove property P.2 for \(T^\xi_C\). We have to show
\[\sigma^\xi(Z(\xi(A)))(\lambda^\xi, \sigma^\xi)_{\xi(A),C}\lambda^\xi(Z(\xi(A))) = (\lambda^\xi, \sigma^\xi)_{\xi(A)}\]
The left hand side equals
\[\sigma^\xi(Z(A))(\lambda^\xi, \sigma^\xi)_{\xi(A),C}\lambda^\xi(Z(A)) = \xi(\sigma(Z(A)))(\lambda^\xi, \sigma^\xi)_{\xi(A),C}\xi(\lambda(Z(A))) = \xi(\sigma(Z(A)))(\lambda, \sigma)_{A,C}\lambda(\lambda(Z(A))) = \xi((\lambda, \sigma)_A)\]
and this coincides, by assumption, with the right hand side.

Now we can apply Theorem 2.27 to obtain a further Hilbert extension \(\{\hat{F}^\xi, G^\xi\}\) where again \(G^\xi \cong G\). Using the uniqueness part of Theorem 2.27 we obtain that both Hilbert extensions are \(\xi(A)\) -module isomorphic.
Proof of Proposition 5.1

It suffices to show that there is one Dirac state, i.e. a state $\omega \in \mathcal{S}(\mathcal{A})$ with $\omega(\mathcal{U}) = 1$. Recall the homomorphism $\zeta : \mathcal{E} \to \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)$. Let $\omega_0 \in \mathcal{S}(\text{CAR}(\mathcal{H}))$ be that quasi-free state which is zero on any normal-ordered monomial of $a(f)$ and $a^*(h)$ of degree greater or equal to 1. Then $\omega_0$ is invariant w.r.t. $\tilde{\gamma}_f$ for all $f \in S(\mathbb{R}^4) \cup \mathbb{R}$. Moreover, since $L(S) \subset \text{Ker} \, B$, there is a state $\omega_1 \in \mathcal{S}(\text{CCR}(S, B))$ such that $\omega_1(\delta_{Lf}) = 1$ for all $f \in S$. Then $\omega_2 := \omega_0 \otimes \omega_1 \in \mathcal{S}(\text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B))$ is a $\tilde{\gamma}_f \otimes \upsilon$-invariant state on $\text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)$ such that $\omega_2(1 \otimes \delta_{Lf}) = 1$ for all $f \in S$. From this we define a state on $\mathcal{E}$ by $\tilde{\omega}_2 := \omega_2 \circ \zeta$ and since $\zeta \circ \check{\gamma}_f = \tilde{\gamma}_f \otimes \upsilon$, it follows that $\tilde{\omega}_2$ is $\check{\beta}_G$-invariant on $\mathcal{E}$. Thus $\tilde{\omega}_2$ extends to a state $\omega_3$ on $\mathcal{A} = G \times \mathcal{E}$ by $\omega_3(U_g) = 1$ for all $g \in G$, where $U_g$ denotes the unitary implementer for $\beta_g$. So $\omega_3 \in \mathcal{S}(\mathcal{A})$ is a Dirac state w.r.t. the unitaries $U_G \cup \delta_{LS}$. Since the maximal set of constraint unitaries for a Dirac state is a group, it follows that for the products $V_f = \delta_{-Lf} \cdot U_{\gamma_f}$ we have $\omega_3(V_f) = 1$ for all $f$, i.e. $\omega_3$ is a Dirac state w.r.t. $\mathcal{U}$, hence $\mathcal{U}$ is first-class.

Proof of Lemma 5.4

Note that $\rho_k$ on the unitary implementers $\rho_k : U_G \to \mathcal{A}$ is a faithful group homomorphism. This is because it is the pointwise product of the identity map $\upsilon$ with the character $\chi_k : U_G \to \mathbb{C}$ given by $\chi_k(U_{\gamma_f}) := e^{ikt}$, $t \in \mathbb{R}$, $f \in S(\mathbb{R}^4)$. Furthermore: $\mathcal{A} = C^*(\rho_k(U_G) \cup \mathcal{E})$. Thus the pair $\{\rho_k(U_G), \mathcal{E}\}$ is also a covariant system for the action $\beta : G \to \text{Aut} \, \mathcal{E}$ (cf. Step 3), hence by the universal property of cross–products (cf. [9]) there is a *-homomorphism $\theta : \mathcal{A} \to \mathcal{A}$ such that $\theta(A) = A$ for $A \in \mathcal{A}$, and $\theta(U_g) = \rho_k(U_g)$ is implementing unitary of the second system. Then $\theta$ coincides with the definition of $\rho_k$ on the generating elements, so it follows that $\rho_k$ extends uniquely to a homomorphism. Since it is clear that $\rho_k$ is bijective (its inverse is $\rho_{-k}$) it follows that $\rho_k$ is an automorphism of $\mathcal{A}$.

Proof of Proposition 5.6

Proof by contradiction. Let $k \neq 0$ and assume $\rho_k \in \text{Inn} \, \mathcal{A}$, i.e. $\rho_k = \text{Ad} \, V$ for some unitary $V \in \mathcal{A}$. Recall the homomorphism $\zeta : \mathcal{E} \to \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)$ encountered in Step 3. Since $(S, B)$ is degenerate, $\zeta(\mathcal{E})$ is not simple which will be inconvenient in the proof below. Choose therefore a maximal ideal $\mathcal{I}$ of $\text{CCR}(S, B)$ (necessarily associated with a character of the Centre $Z(\text{CCR}(S, B))$, and let $\eta : \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B) \to \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)/\mathcal{I}$ be the factorisation by the ideal $1 \otimes \mathcal{I}$. Then the composition $\xi := \eta \circ \zeta : \mathcal{E} \to \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)/\mathcal{I}$ is a homomorphism of which the image is a simple algebra.

Now the action $\beta : G \to \text{Aut} \, \mathcal{E}$ (Step 4) only affects $\text{CAR}(\mathcal{H})$ in $\mathcal{E}$, so preserves the ideal generated by the commutators $[\text{CAR}(\mathcal{H}), \text{CCR}(S, B)]$ in $\mathcal{E}$ as well as the ideal $1 \otimes \mathcal{I}$. Thus each $\beta_g$ can be taken through the homomorphism $\xi$ to define an action $\beta^\xi : G \to \text{Aut} (\text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)/\mathcal{I})$ and it is just $\beta^\xi_{\gamma_f} = \tilde{\gamma}_f \otimes \upsilon$. Thus we can extend $\xi$ from $\mathcal{E}$ to $\mathcal{A} = G \times \mathcal{E}$ to get a surjective homomorphism $\xi : \mathcal{A} \to G \times \beta^\xi (\text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)/\mathcal{I})$. 

34
Now $\rho_k \in \text{Aut}\ A$ only affects $U_G$, leaving $\mathcal{E}$ invariant, hence it preserves $\text{Ker}\ \xi \subset A$. Thus $\rho_k$ can be factored through $\xi$ to obtain the automorphisms $\rho^\xi_k \in \text{Aut}\ \xi(A)$ by

$$\rho^\xi_k(\xi(A)) := \xi(\rho_k(A)) \quad \forall \ A \in A, \quad \text{and so} \quad \rho^\xi_k = \text{Ad} \, \xi(V). \quad (12)$$

Recall now that each element of the discrete crossed product $\xi(A) = G \times^\beta \xi(\mathcal{E})$ (with $\xi(\mathcal{E}) = \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)/\mathcal{I}$) can be written as a C*-norm convergent series $\sum_{n=1}^\infty B_n U_{g_n}$ where $B_n \in \xi(\mathcal{E})$ and $g_n \in G$, (with $g_n$ distinct for different $n$) and that the unitaries $U_G$ form a left $\xi(\mathcal{E})$–module basis. In particular, for the implementing unitaries $\xi(V)$ of $\rho^\xi_k$ we have a series $\xi(V) = \sum_{n=1}^\infty B_n U_{g_n}$, $B_n \in \xi(\mathcal{E})\setminus\{0\}$. Since $\rho_k |_\mathcal{E} = \iota$, it follows from equation (12) that $\xi(V)A = A\xi(V)$ for all $A \in \xi(\mathcal{E})$, i.e.

$$A\xi(V) = \sum_{n=1}^\infty AB_n U_{g_n} = \xi(V)A = \sum_{n=1}^\infty B_n U_{g_n} A = \sum_{n=1}^\infty B_n \beta^\xi_{g_n}(A) U_{g_n}$$

for all $A \in \xi(\mathcal{E})$. So by the basis property of $U_G$ we have

$$AB_n = B_n \beta^\xi_{g_n}(A) \quad \forall \ A \in \xi(\mathcal{E}) = \text{CAR}(\mathcal{H}) \otimes \text{CCR}(S, B)/\mathcal{I}. \quad (13)$$

Since $\beta^\xi_{g_n} |_\text{CCR}(S, B)/\mathcal{I} = \iota$, this implies that $B_n \in (\text{CCR}(S, B)/\mathcal{I})'$. From the fact that CCR$(S, B)/\mathcal{I}$ is simple (hence has trivial centre) this means that $B_n \in \text{CAR}(\mathcal{H}) \otimes \mathbb{1}$, and hence equation (13) claims that $B_n$ is a nonzero intertwiner between $\iota$ and $\beta^\xi_{g_n}$ in CAR$(\mathcal{H})$. We next prove that $B_n$ is invertible, in which case $\beta^\xi_{g_n}$ becomes inner on CAR$(\mathcal{H})$.

Let $\pi : \text{CAR}(\mathcal{H}) \to B(\mathcal{L})$ be any faithful irreducible representation of CAR$(\mathcal{H})$ on a Hilbert space $\mathcal{L}$ e.g. the Fock representation), and let $\psi \in \text{Ker}\ \pi(B_n)$. Then by (13)

$$\pi(B_n A) \psi = \pi(\beta_{g_n}^{-1}(A)) A \pi(B_n) \psi = 0 \quad \forall \ A \in \text{CAR}(\mathcal{H}).$$

Thus $\pi(\text{CAR}(\mathcal{H})) \psi \subseteq \text{Ker}\ \pi(B_n)$ . However, in an irreducible representation every nonzero vector is cyclic, so either $\psi = 0$ or $\pi(B_n) = 0$, and the latter case is excluded by $B_n \neq 0$, $\pi$ faithful. Thus $\psi = 0$, i.e. we’ve shown that $\ker \pi(B_n) = \{0\}$. Moreover by equation (13) we have

$$\pi(A) \pi(B_n) \varphi = \pi(B_n) \pi(\beta_{g_n}^{-1}(A)) \varphi \quad \forall \varphi \in \mathcal{L}\setminus\{0\}, \ A \in \text{CAR}(\mathcal{H})$$

hence $\pi(\text{CAR}(\mathcal{H})) \pi(B_n) \varphi \subseteq \text{Ran} \pi(B_n)$ for all $\varphi \in \mathcal{L}\setminus\{0\}$. Now $\pi(B_n) \varphi \neq 0$ (by $\ker \pi(B_n) = \{0\}$) and so by Dixmier 2.8.4 [20] we have that $\pi(\text{CAR}(\mathcal{H})) \pi(B_n) \varphi \neq \mathcal{L}$ (no closure is necessary). Thus $\text{Ran} \pi(B_n) = \mathcal{L}$, i.e. $\pi(B_n)$ is invertible, and so since $\pi$ is faithful (hence preserves the spectrum of an element) it follows that $B_n$ is also invertible in CAR$(\mathcal{H})$.

Using the fact that $B_n$ is invertible, equation (13) becomes $\beta_{g_n}^{-1}(A) = B_n^{-1} AB_n$ for all $A \in \text{CAR}(\mathcal{H})$. Since $\beta_{g_n}$ is a *-homomorphism, this implies that $B_n^{-1} A^* B_n = B_n^* A^* (B_n^{-1})^*$, i.e. $B_n B_n^* A^* = A^* B_n B_n^*$ for all $A \in \text{CAR}(\mathcal{H})$, and since CAR$(\mathcal{H})$ has trivial centre, this means $B_n B_n^* \in \mathbb{C} \mathbb{1}$. Put $B_n B_n^* = t_n$ (necessarily $t_n > 0$) then $U_n := B_n/\sqrt{t_n}$ satisfies $U_n U_n^* = \mathbb{1}$. By substituting $A$ by $\beta_{g_n}^{-1}(A)$ in (13) we also obtain $B_n^* B_n \in \mathbb{C} \mathbb{1}$ by the above argument, then using $t_n = \|B_n B_n^*\|^2 = \|B_n\|^2 = \|B_n^* B_n\| = B_n^* B_n$ we get also $U_n^* U_n = \mathbb{1}$. Thus

$$\beta_{g_n}^{-1}(A) = B_n^{-1} AB_n = \left(\frac{B_n}{\sqrt{t_n}}\right)^{-1} A \left(\frac{B_n}{\sqrt{t_n}}\right) = U_n^* AU_n$$
for \( A \in \text{CAR}(\mathcal{H}) \), i.e., \( \beta_{g_n} \) is inner on \( \text{CAR}(\mathcal{H}) \). Recall however, that on \( \text{CAR}(\mathcal{H}) \) \( \beta_{g_n} \) is just an automorphism \( \tilde{\gamma}_{f_n} \) for some \( f_n \in \mathcal{S}(\mathbb{R}^4) + \mathbb{R} \), coming from a Bogoliubov transformation: \( \tilde{\gamma}_{f_n}(\Phi(k)) := \Phi(T_{f_n}k) \) (cf. Step 4). So for \( \beta_{g_n} \) to be inner on \( \text{CAR}(\mathcal{H}) \), this means that either of \( I \pm T_{f_n} \) must be trace-class (cf. Theorem 4.1, p48 of Araki \[1\] or Theorem 4.1.4 in \[29\]). However

\[
T_{f_n}(h_1 + h_2) := e^{-if_n h_1} + e^{if_n h_2} \quad \forall \, h_i \in \mathcal{H} = L^2(\mathbb{R}^4).
\]

Now for any \( f_n \) such that \( T_{f_n} \neq I \), it is clear that the multiplication operators on \( L^2(\mathbb{R}^4) \) by \( (I \pm e^{\pm if_n}) \) cannot be trace-class. This contradicts our finding that \( \beta_{g_n} \) is inner if \( g_n \neq e \), hence only \( g_n = e \) is possible in the series \( \xi(V) = \sum_{n=1}^{\infty} B_n U_{g_n} \) i.e. \( \xi(V) = B \cdot U_e \), \( B \in \xi(\mathcal{E}) \setminus \{0\} \).

But in this case equation \[13\] becomes \( AB = BA \) for all \( A \in \xi(\mathcal{E}) \) and so since \( \xi(\mathcal{E}) \) is simple, \( B \in \mathbb{C} \cdot 1 \). This however implies that \( \iota = \text{Ad} \xi(V) = \rho_k \) which cannot be because \( \rho_k(U_{\gamma_1}) = e^{ikt} U_{\gamma_1} \) factors unchanged through \( \xi \). From this contradiction, it follows that our initial assumption \( \rho_k \in \text{Inn} \mathcal{A} \) is false.
