AUTOMORPHY OF MOD 2 GALOIS REPRESENTATIONS ASSOCIATED TO CERTAIN GENUS 2 CURVES OVER TOTALLY REAL FIELDS

ALEXANDRU GHITZA AND TAKUYA YAMAUCHI

Abstract. Given a genus two hyperelliptic curve $C$ over a totally real field $F$, we show that the mod 2 Galois representation $\overline{\rho}_{C,2}: \text{Gal}( \overline{F}/F) \rightarrow \text{GSp}_4(\mathbb{F}_2)$ attached to $C$ is residually automorphic when the image of $\overline{\rho}_{C,2}$ is isomorphic to $S_5$ and it is also a transitive subgroup under a fixed isomorphism $\text{GSp}_4(\mathbb{F}_2) \cong S_6$. More precisely, there exists a Hilbert–Siegel Hecke eigen cusp form $h$ on $\text{GSp}_4(A_F)$ of parallel weight two whose mod 2 Galois representation $\rho_{h,2}$ is isomorphic to $\rho_{C,2}$.

1. Introduction

Let $K$ be a number field in an algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$ and $p$ be a prime number. In proving automorphy of a given geometric $p$-adic Galois representation $\rho: G_K := \text{Gal}(\overline{\mathbb{Q}}/K) \rightarrow \text{GL}_n(\mathbb{Q}_p)$, a first step would be, typically, to observe residual automorphy of its mod $p$ reduction $\overline{\rho}: G_K \rightarrow \text{GL}_n(\overline{\mathbb{F}}_p)$ obtained after choosing a suitable integral lattice. However, proving residual automorphy of $\overline{\rho}$ is hard unless the image of $\overline{\rho}$ is reasonable so that one can apply the current results in the theory of automorphic representations. For instance, if the image is solvable, one can use the Langlands base change argument to find an automorphic cuspidal representation as is done in many known cases (cf. [34], [42], [11], [29], [45]). Another natural problem is to find geometric objects whose residual Galois representations have suitably small images in question so that one can apply the various known results for automorphy of Galois representations.

In this paper, we study residual automorphy of mod 2 Galois representations associated to certain hyperelliptic curves of genus 2. Let us fix some notation to explain our results. Let $F$ be a totally real field and fix an embedding $F \subset \mathbb{Q}$. Let us consider the hyperelliptic curve over $F$ of genus 2 defined by

$$C: \quad y^2 = f(x) := x^6 + a_1x^5 + \cdots + a_5x + a_6, \quad a_1, \ldots, a_6 \in F.$$  

Let $D_f$ be the discriminant of $f$. If we write $f(x) = \prod_{i=1}^6(x - \alpha_i)$ over $\mathbb{Q}$, then $D_f = \prod_{1 \leq i < j \leq 6} (\alpha_i - \alpha_j)^2$. By abusing the notation, we also denote by $C$ a unique smooth completion of the above hyperelliptic curve. Let $J = \text{Jac}(C)$ be the Jacobian variety of $C$ and for each positive integer $n$, let $J[n]$ be the group scheme of $n$-torsion points. Let $T_{J,2}$ be the 2-adic Tate module over $\mathbb{Z}_2$ associated to $J$. Let $\langle *, * \rangle: T_{J,2} \times T_{J,2} \rightarrow \mathbb{Z}_2(1)$ be the Weil pairing, which is $G_F$-equivariant, perfect, and alternating. It yields an integral 2-adic Galois representation

$$\rho_{C,2}: G_F \rightarrow \text{GSp}(T_{J,2}, \langle *, * \rangle) \cong \text{GSp}_4(\mathbb{Z}_2).$$

where the algebraic group \( \text{GSp}_4 = \text{GSp}_J \) is the symplectic similitude group in \( \text{GL}_4 \) associated to \( \begin{pmatrix} 0 & s \\ -s & 0 \end{pmatrix}, \ s = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \). Put

\[
\overline{T}_{J,2} = T_{J,2} \otimes_{\mathbb{Z}_2} \mathbb{F}_2 = J[2](\mathbb{Q}).
\]

This yields a mod 2 Galois representation

\[
(1.2) \quad \overline{\rho}_{C,2}: G_F \longrightarrow \text{GSp}(\overline{T}_{J,2}, \langle *, * \rangle_{\mathbb{F}_2}) \simeq \text{GSp}_4(\mathbb{F}_2).
\]

On the other hand, we can embed the Galois group \( \text{Gal}(F/J) \) of the splitting field of \( f \) over \( F \) into \( S_6 \) by permutation of the roots of \( f(x) \); we denote this embedding by \( \iota_f: \text{Gal}(F/J) \hookrightarrow S_6 \). Here \( S_n \) stands for the \( n \)-th symmetric group. Since \( \overline{T}_{J,2} \) is generated (cf. \[32\]) by divisors associated to the points \((x,0)\) in \( C(\overline{\mathbb{Q}}) \), \( \overline{\rho}_{C,2} \) factors through \( \text{Gal}(F/J) \); we denote it by \( \overline{\rho}_{C,2}: \text{Gal}(F/J) \hookrightarrow \text{GSp}_4(\mathbb{F}_2) \) again. A subgroup \( H \) of \( S_6 \) is transitive if it acts on the set \( \{1,2,3,4,5,6\} \) transitively. Let us fix an isomorphism \( \text{GSp}_4(\mathbb{F}_2) \simeq S_6 \) commuting with \( \overline{\rho}_{C,2} \) and \( \iota_f \).

In this situation we will prove the following:

**Theorem 1.1.** Keep the notation as above. Suppose that \( \text{Im}(\overline{\rho}_{C,2}) \simeq S_6 \) and it is a transitive subgroup of \( S_6 \) via the fixed isomorphism between \( \text{GSp}_4(\mathbb{F}_2) \) and \( S_6 \). Further assume that for any complex conjugation \( c \) in \( G_F \), \( \overline{\rho}_{C,2}(c) \) is of type \((2,2)\) as an element of \( S_6 \). Then there exists a Hilbert–Siegel Hecke eigen cusp form \( h \) on \( \text{GSp}_4(\mathbb{A}_F) \) of parallel weight 2 such that \( \overline{\rho}_{h,2} \simeq \overline{\rho}_{C,2} \) as a representation to \( \text{GL}_4(\mathbb{F}_2) \), where \( \overline{\rho}_{h,2} \) is the reduction modulo 2 of the 2-adic representation \( \rho_{h,2} \) associated to \( h \) (see Section 3.1 for \( \rho_{h,2} \)).

We give some remarks on the above theorem. The transitivity of the image implies \( f(x) \) is irreducible over \( F \). Put \( L = F(\sqrt{D_f}) \). It is corresponding to the kernel of \( \text{sgn} \circ \iota_f \circ \overline{\rho}_{C,2}: G_F \longrightarrow \{ \pm 1 \} \) where \( \text{sgn}: S_6 \longrightarrow \{ \pm 1 \} \) is the usual sign character. The assumption on \( \overline{\rho}_{C,2}(c) \) shows \( f(x) \) has only two real roots and the other four complex roots are permuted by an element of type \((2,2)\) in \( S_6 \). Therefore, \( D_f \in F \) is totally real and it is not a square element since \( \text{Im}(\overline{\rho}_{C,2}) \simeq S_5 \). In conclusion, \( L/F \) is a totally real quadratic extension. Then it will turn out that \( \overline{\rho}_{C,2} \) is an induced representation to \( G_F \) of a certain totally odd 2-dimensional mod 2 Galois representation \( \overline{T}: G_L \longrightarrow \text{GL}_2(\mathbb{F}_2) \) whose image is isomorphic to \( A_5 \). Applying Sasaki’s result \[33\] (or Pillon–Stroh’s result \[28\]), the Jacquet–Langlands correspondence, and a suitable congruence method, one can find a Hilbert cusp form \( g \) of parallel weight 2 on \( \text{GL}_2(\mathbb{A}_L) \) whose corresponding mod 2 Galois representation \( \overline{\rho}_{g,2} \) is isomorphic to \( \overline{T} \). Then the theta lift of the corresponding automorphic representation \( \pi_g \) to \( \text{GSp}_4(\mathbb{A}_F) \) yields a cuspidal automorphic representation \( \Pi \) of \( \text{GSp}_4(\mathbb{A}_F) \) which is generated by a Hilbert–Siegel Hecke eigen cusp form \( h \) of parallel weight 2 on \( \text{GSp}_4(\mathbb{A}_F) \). By Theorem 1.1 of \[44\], for each \( p \) in a set of primes of Dirichlet density one, the Hodge–Tate weights at \( p \) of the \( p \)-adic Galois representation attached to \( \Pi \) are \( \{0,0,1,1\} \). It is also true for \( p = 2 \) when \( \Pi_2 \) is unramified and the roots of the 2-nd Hecke polynomial of \( \Pi \) are pairwise distinct (see Theorem 3.3 of \[31\]). On the other hand, the Hodge–Tate weights of \( \rho_{C,2} \) at the place dividing 2 are always \( \{0,0,1,1\} \) and this is why we seek a form \( h \) of such weight.

We note that \( J \) is potentially automorphic by Theorem 1.1.3 of \[4\] and the potential version of Theorem 1.1 is already known in a more general setting.

**Remark 1.2.**

1. The construction of Hilbert–Siegel modular forms in Theorem 1.1 is similar to the one in \[41\]. However, to apply theta lifting to \( \text{GSp}_4 \), we need to carefully look at the central characters after a congruence method (see Proposition 3.8).

2. In the main theorem, we do not specify the levels of the Hilbert–Siegel forms because of the lack of level-lowering results (see Remark 3.9). However, \( h \) could be a paramodular form by using the method of \[22\] at least when \( F = \mathbb{Q} \) so that the situation is compatible with the paramodular conjecture \[8\] Conjecture 1.4).
(3) In the course of the proof for the main theorem, we do not use the results in \([17]\) to
associate a form with a Galois representation though it is necessary to state Theorem
\([3.7]\). Instead, we apply the unconditional result in \([39]\) to construct a corresponding
automorphic cuspidal representation. Hence Theorem \([1.1]\) is true unconditionally.
(4) The central character of \(h\) can be read off from Theorem \([3.6]\) and Proposition \([3.8]\).
(5) We can weaken the condition on the image of \(\overline{\rho}_{C,2}\) by requiring that the image be
isomorphic to \(F_{20} := C_4 \times C_5\), or isomorphic to \(A_5\) with \(F/\mathbb{Q}\) of even degree. In the \(F_{20}\)
case, we have a similar cuspidal representation. In the \(A_5\) case, \(\overline{\rho}_{C,2}\) is reducible so we
can naively attach a non-cuspidal automorphic representation. By using a congruence
method, we may hope to obtain a cuspidal representation in either case but we do not
pursue it in this article.

This paper is organized as follows. In Section \([2]\) we consider some basic facts about mod 2
Galois representations to \(\text{GSp}_4(\mathbb{F}_2)\). We devote Section \([3]\) to the study of the automorphic forms
in question and to various congruences between several types automorphic forms, and apply this
to the proof of automorphy of our representations in \([3.3]\). Finally, in Section \([4]\) we describe how
to obtain explicit families of examples using two constructions: the first coming from a classical
result of Hermite, and the second from 5-division points on elliptic curves following Goins \([19]\).

### 2. Certain mod 2 Galois representations to \(\text{GSp}_4(\mathbb{F}_2)\)

In this section, we study some properties of mod 2 Galois representations to \(\text{GSp}_4(\mathbb{F}_2)\). We refer to \([9\,\text{Section 5}]\) and \([41\,\text{Section 3}]\). We denote by \(S_n\) the \(n\)-th symmetric group, by \(A_n\)
the \(n\)-th alternating group, and by \(C_n\) the cyclic group of order \(n\).

#### 2.1. \(\text{GSp}_4\). Let us introduce the smooth group scheme \(\text{GSp}_4 = \text{Sp}_4\) over \(\mathbb{Z}\) which is defined as the
symplectic similitude group in \(\text{GL}_4\) associated to \(J := \begin{pmatrix} 0 & 2 \\ -s & 0 \end{pmatrix}\), \(s = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\). Explicitly,
\[
\text{GSp}_4 = \{ X \in \text{GL}_4 \mid t X J X = \nu(X) J, \exists \nu(X) \in \text{GL}_1 \}.
\]
Put \(\text{Sp}_4 = \text{Ker}(\nu: \text{GSp}_4 \rightarrow \text{GL}_1, X \mapsto \nu(X))\).

#### 2.2. An identification between \(\text{GSp}_4(\mathbb{F}_2)\) and \(S_6\). Let \(s: \mathbb{F}_2^6 \rightarrow \mathbb{F}_2\) be the linear functional
defined by \(s(x_1, \ldots, x_6) = x_1 + \cdots + x_6\). Put \(V = \{ x \in \mathbb{F}_2^6 \mid s(x) = 0 \}\) and \(W = V/U\) where
\(U = \langle (1, 1, 1, 1, 1, 1) \rangle\). Let us consider the bilinear form on \(\mathbb{F}_2^6\) given by the formula
\[
\langle x, y \rangle = x_1 y_1 + \cdots + x_6 y_6, \quad x, y \in \mathbb{F}_2^6.
\]
It induces a non-degenerate, alternating pairing \(\langle *, * \rangle_W\) on \(W\), where being alternating means
that \(\langle x, x \rangle_W = 0\) for each \(x \in W\). The symmetric group \(S_6\) acts naturally on \(\mathbb{F}_2^6\) and it yields a
group homomorphism
\[
\varphi: S_6 \rightarrow \text{GSp}_{2}(W, \langle *, * \rangle_W) \simeq \text{GSp}_4(\mathbb{F}_2).
\]
The action of \(S_6\) on \(W\) is faithful. In fact, we can check it only for \((12)\) and \((123456)\) generating
\(S_6\). By direct computation,
\[
|\text{GSp}_4(\mathbb{F}_2)| = \text{Sp}_4(\mathbb{F}_2) = 720 = |S_6|
\]
and therefore, \(\varphi\) is an isomorphism.

It is easy to find a basis of \(W\). For instance, we see that
\[
e_1 = (1, 1, 0, 0, 0, 0), \quad e_2 = (0, 0, 0, 1, 1, 0),
e_3 = (0, 0, 0, 1, 0, 1), \quad e_4 = (1, 0, 1, 0, 0, 0)
\]
(2.1)
form a basis of $W$. The representation matrices with respect to the above basis for the generators (12) and (123456) of $S_6$ are given respectively as follows:

$$(2.2) \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}. $$

2.3. $S_5$-representations to $\text{GSp}_4(F_2)$. It follows from [9] Section 5] (in particular, the table in Lemma 5.1.7 in loc.cit.) that, up to conjugacy, there are two embeddings from $S_5$ to $\text{GSp}_4(F_2) \simeq S_6$ which are absolutely irreducible as representations to $\text{GL}_4(F_2)$. We denote the images by $S_5(a), S_5(b)$ respectively; they are characterized in terms of the trace as follows:

1. (type $S_5(a)$) the elements of order 3 have trace 0 and are of type $(3,3)$,
2. (type $S_5(b)$) the elements of order 3 have trace 1 and are of type $(3)$.

Under the identification $\text{GSp}_4(F_2) \simeq S_6$, these subgroups are given explicitly as

$$(2.3) S_5(a) = \langle \sigma_6 : = (12346), \sigma_{23} : = (12)(34)(56) \rangle,$$

$S_5(b) = \{ \sigma \in S_6 \mid \sigma(6) = 6 \}.$

Notice that $\sigma_{23}(\sigma_6 \sigma_{23} \sigma_6^{-1})$ is of type $(3,3)$ and $(\sigma_6 \sigma_{23})^2 = (16)(35)$ is obviously of type $(2,2)$ which is explicitly given by

$$
\begin{pmatrix}
0 & 1 & 1 & 0 \\
1 & 1 & 1 & 1 \\
0 & 1 & 1 & 1 \\
1 & 0 & 1 & 0
\end{pmatrix}
$$

with respect to the basis $(2.1)$. By direct computation, one can check it is conjugate to $J$ by

$$
\begin{pmatrix}
1 & 0 & 1 & 0 \\
0 & 1 & 1 & 1 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix} \in \text{GSp}_4(F_2).
$$

Let $G$ be a group and $\overline{\rho}: G \rightarrow \text{GSp}_4(F_2)$ a representation of $G$. Since any element of $\text{GSp}_4(F_2) = \text{Sp}_4(F_2)$ has determinant one, $\overline{\rho}$ is automatically self-dual.

**Lemma 2.1.** Assume that $\text{Im}(\rho) \simeq S_5$. Then $\rho$ is absolutely irreducible. Furthermore, there exist an index 2 subgroup $H$ of $G$, a generator $\iota$ of $G/H$, and an absolutely irreducible representation $\overline{\tau}: H \rightarrow \text{GL}_2(F_4)$ which is not equivalent to $\tau$ defined by $\tau(h) = \overline{\tau}(\iota h \iota^{-1})$ for each $h \in H$ such that

1. $\text{Im}(\overline{\tau}) = \text{SL}_2(F_4) \simeq A_5$;
2. if $\text{Im}(\rho)$ is of type $S_6(a)$, then $\rho \simeq \text{Ind}_H^G \tau$;
3. if $\text{Im}(\rho)$ is of type $S_6(b)$, then $\rho$ is isomorphic to a twisted tensor product with respect to $G/H$ (see [11] Section 3)).

**Proof.** Put $H := \rho^{-1}(A_5)$. Clearly it is a subgroup of $G$ of index 2. Since $\text{Im}(\rho) \simeq S_5$, by Dickson’s result [13] p.128, (2.1)], $\overline{\rho}$ is absolutely irreducible. Then by Clifford’s theorem, it follows that $\rho|_H$ is either absolutely irreducible (by Dickson’s result again) or a sum of two 2-dimensional irreducible representations $\overline{\tau}, \overline{\tau}': G \rightarrow \text{GL}_2(F_2)$ after base extension to $F_2$. In the latter case, by Schur’s Lemma and Frobenius reciprocity,

$$1 \leq \dim \text{Hom}_H(\rho|_H, \overline{\tau}) = \dim \text{Hom}_G(\rho, \text{Ind}_H^G \overline{\tau}) \leq 1,$$

therefore both have the same dimension and $\rho$ is irreducible. Further, irreducibility implies that $\tau$ cannot be isomorphic to $\overline{\tau}$. Since $A_5 \simeq \text{SL}_2(F_4)$ (cf. [11] Section 3.3]), we may assume $\overline{\tau}$ takes values in $F_4$ as desired. Further, by using $(2.2)$ and $(2.3)$, one can distinguish the types in terms of the trace.

The remaining (absolutely irreducible) case follows from [11] Proposition 3.5-(1)].

Fix an isomorphism $\text{GSp}_4(F_2) \simeq S_6$ as in Section 2.2.
Remark 2.2. Keep the notation as above (recall that Im(\(\rho\)) \(\simeq S_5\)). The type of the image Im(\(\rho\)) can also be characterized in the following way:

1. (type \(S_5(a)\)) it is a transitive subgroup of \(S_6\);
2. (type \(S_5(b)\)) it is not transitive, hence up to conjugacy, it fixes 6 as a subgroup of \(S_6\).

In this article, we focus on the case of type \(S_5(a)\); the other case is studied in [41].

Proposition 2.3. Let \(F\) be a totally real field. Let \(\rho: G_F \to GSp_4(\mathbb{F}_2)\) be an irreducible mod 2 Galois representation. Suppose that Im(\(\rho\)) is of type \(S_5(a)\). Assume further that for each complex conjugation \(c\) of \(G_F\), \(\rho(c)\) is of type \((2,2)\). Then there exists a totally real quadratic extension \(L/F\) with \(\text{Gal}(L/F) = \langle i \rangle\) and an irreducible totally odd Galois representation \(\tau: GL_2(\mathbb{F}_4) \to GL_2(\mathbb{F}_4)\) which is not equivalent to \(\overline{\tau}\) satisfying

1. \(\text{Im}(\tau) \simeq \text{SL}_2(\mathbb{F}_4) \simeq A_5\);
2. \(\overline{\tau} \simeq \text{Ind}^G_G \tau\) as a representation to \(GL_4(\mathbb{F}_4)\);
3. for each complex conjugation \(c\) of \(G_F\), \(\tau(c)\) is conjugate to \(s = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\).

Here the totally odd-ness for \(\overline{\tau}\) exactly means the third condition above.

Proof. Let \(L/F\) be the quadratic extension corresponding to the sign character \(\text{sgn}\): Im(\(\rho\)) \(\simeq S_5\). By assumption \(L/F\) is a totally real quadratic extension and we have \(\rho(G_L) \simeq A_5\) (see the explanation right after Theorem 1.1). The first two claims follow from Lemma 2.1. Further, by assumption, for each complex conjugation \(c\) of \(G_F\), \(\rho(c)\) is conjugate to \(J\) (see the paragraph right after (2.3)). The third claim follows from this. \(\square\)

3. Automorphy

Fix an embedding \(\overline{\mathbb{Q}} \hookrightarrow \mathbb{C}\) and an isomorphism \(\overline{\mathbb{Q}}_p \cong \mathbb{C}\) for each prime \(p\). Let \(\iota = \iota_p: \overline{\mathbb{Q}} \hookrightarrow \overline{\mathbb{Q}}_p\) be an embedding that is compatible with the maps \(\overline{\mathbb{Q}} \hookrightarrow \mathbb{C}\) and \(\overline{\mathbb{Q}}_p \cong \mathbb{C}\) fixed above.

3.1. Automorphic Galois representations. Let \(F\) be a totally real field. For each place \(v\) of \(F\), let \(F_v\) be the completion of \(F\) at \(v\). In this section we recall basic properties of cuspidal automorphic representations of \(GSp_4(A_F)\) such that each infinite component is a (limit of) discrete series representation. We basically follow the notation of Mok’s article [27] and add ingredients necessary for our purpose.

For any place \(v\) of \(F\), we denote by \(W_{F_v}\) the Weil group of \(F_v\). Let \(m_1, m_2, w\) be integers such that

\[ m_1 > m_2 \geq 0 \quad \text{and} \quad m_1 + m_2 \equiv w + 1 \pmod{2}. \]

Let \(a = (m_1 + m_2)/2, b = (m_1 - m_2)/2\), and consider the \(L\)-parameter \(\phi_{(w;m_1,m_2)}: W_{\mathbb{R}} \to GSp_4(\mathbb{C})\) defined by

\[ \phi_{(w;m_1,m_2)}(z) = |z|^{-w} \text{diag} \left( \left( \frac{z}{\overline{z}} \right)^a, \left( \frac{z}{\overline{z}} \right)^b, \left( \frac{\overline{z}}{z} \right)^{-b}, \left( \frac{\overline{z}}{z} \right)^{-a} \right) \]

and

\[ \phi_{(w;m_1,m_2)}(j) = \begin{pmatrix} 0_2 & (-1)^{w+1} I \end{pmatrix} s \begin{pmatrix} 0_2 \\ 0_2 \end{pmatrix}, \quad s = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \]

The archimedean \(L\)-packet \(\Pi(\phi_{(w;m_1,m_2)})\) corresponding to \(\phi_{(w;m_1,m_2)}\) under the Local Langlands Correspondence consists of two elements

\[ \left\{ \pi^H_{(w;m_1,m_2)}, \pi^W_{(w;m_1,m_2)} \right\} \]

whose central characters both satisfy \(z \mapsto z^{-w}\) for \(z \in \mathbb{R}^\times\). These are essentially tempered unitary representations of \(GSp_4(\mathbb{R})\) and tempered exactly when \(w = 0\). Let \(K\) be a maximal compact subgroup of \(Sp_4(\mathbb{R})\). When \(m_2 \geq 1\) (resp. \(m_2 = 0\)) the representation \(\pi^H_{(w;m_1,m_2)}\) is called a (resp. limit of) holomorphic discrete series representation of minimal \(K\)-type \(k = (k_1, k_2) := (m_1 + 1, m_2 + 2)\) which corresponds to an algebraic representation.
\( V_2 := \text{Sym}^{k_1-k_2} \text{St}_2 \otimes \text{det}^{k_2} \text{St}_2 \) of \( K_{\mathbb{C}} = \text{GL}_2(\mathbb{C}) \) where \( \text{St}_2 \) stands for the 2-dimensional standard algebraic representation of \( K_{\mathbb{C}} \). If \( m_2 \geq 1 \) (resp. \( m_2 = 0 \)), the representation \( \pi_{W(m_1,m_2)} \) is called a (resp. limit of) large (or generic) discrete series representation of minimal \( K \)-type \( V_{(m_1+1,-m_2)} \). We say that a cuspidal automorphic representation \( \pi \) of \( \text{GSp}_4(\mathbb{A}_F) \) is regular if for each infinite place \( v \), \( \pi_v \) is a discrete series representation.

Fix an integer \( w \). Let \( \pi = \otimes_v \pi_v \) be an automorphic cuspidal representation of \( \text{GSp}_4(\mathbb{A}_F) \) such that for each infinite place \( v \), \( \pi_v \) has \( L \)-parameter \( \phi_{(w;m_1,v,m_2,v)} \) with the parity condition \( m_1,v + m_2,v \equiv w + 1 \) (mod 2). Let \( \text{Ram}(\pi) \) be the set of all finite places at which \( \pi_v \) is ramified.

For the existence of Galois representations attached to regular algebraic self-dual cuspidal representations for general linear groups, see Theorem 1.1 of [1], which is the main reference for knowing the main contributors (Harris–Taylor, Shin, and others) as well as the latest results up to the time when loc. cit. appeared. In order to attach Galois representations for \( \text{GSp}_4 \), both Sorensen [27] and Mok [27] use Langlands functoriality from \( \text{GSp}_4 \) to \( \text{GL}_4 \) and reduce the problem to the known cases for general linear groups (specifically \( \text{GL}_4 \)). Sorensen focused on the case when the representation at any infinite place is generic (large discrete series) while Mok treated the limit of discrete series via a congruence method. Mok relied on results of Arthur that were at the time expected but not yet proved, and which are now guaranteed by [17] though remaining conditional on Arthur’s classification. We summarize here the known results taken from Theorem 3.1 (for the regular case) and Theorem 4.14 of [27] (see also Theorem 3.1 and Theorem 3.3 of [44] as a good summary):

**Theorem 3.1.** Assume that \( \pi \) is neither CAP nor endoscopic. For each prime \( p \) and \( t_p : \overline{\mathbb{Q}}_p \to \mathbb{C} \) there exists a continuous, semisimple Galois representation \( \rho_{\pi,t_p} : G_F \to \text{GSp}_4(\overline{\mathbb{Q}}_p) \) such that

1. \( \nu \circ \rho_{\pi,t_p}(c_\infty) = -1 \) for any complex conjugation \( c_\infty \) in \( G_F \).
2. \( \rho_{\pi,t_p} \) is unramified at all finite places that do not belong to the set \( \text{Ram}(\pi) \cup \{\nu\} \).
3. For each finite place \( v \) not lying over \( p \), the local-global compatibility holds:
   
   \[
   \text{rec}^\text{GT}_v \left( \pi_v \otimes |\nu|^{-\frac{3}{2}} \otimes |\nu|^{-\frac{3}{2}} \right) \cong \begin{cases} \text{WD}(\rho_{\pi,t_p}|_{G_{F_v}})^{F-ss} & \text{if } \pi \text{ is regular,} \\ \text{WD}(\rho_{\pi,t_p}|_{G_{F_v}})^{ss} & \text{otherwise,} \end{cases}
   \]
   
   with respect to \( t_p \), where \( \text{rec}^\text{GT}_v \) stands for the local Langlands correspondence constructed by Gan–Takeda [13].

4. For each \( v | p \) and each embedding \( \sigma : F_v \to \overline{\mathbb{Q}}_p \), let \( \nu_{\sigma} : F \to \mathbb{C} \) denote the embedding \( \nu_{\sigma} := t_p \circ \sigma \). Then the representation \( \rho_{\pi,t_p}|_{G_{F_v}} \) has Hodge–Tate weights
   
   \[
   \text{HT}_{\sigma}(\rho_{\pi,t_p}|_{G_{F_v}}) = \left\{ \delta_{v_0}, \delta_{v_0} + m_2,v_0, \delta_{v_0} + m_1,v_0, \delta_{v_0} + m_2,v_0 + m_1,v_0 \right\}
   \]
   
   where \( \delta_{v_0} = \frac{1}{2}(w + 3 - m_1,v_0 - m_2,v_0) \);

5. Further,
   
   (a) if \( \pi_{v'} \) is discrete series for all infinite places \( v' \), then for each finite place \( v \) of \( F \), \( \rho_{\pi,t_p}|_{G_{F_v}} \) is of de Rham and the local-global compatibility also holds up to Frobenius semi-simplification;
   
   (b) for each finite place \( v \) such that \( \pi_v \) is unramified and the Satake parameters of \( \pi \) are distinct from each other, \( \rho_{\pi,t_p}|_{G_{F_v}} \) is crystalline and the local-global compatibility also holds up to semi-simplification.

**Remark 3.2.**

1. Regarding the fourth statement of the above theorem, when \( \pi \) is not regular, in general, we do not even know if \( \rho_{\pi,t_p}|_{G_{F_v}} \) is Hodge–Tate for each \( v | p \) such that \( \pi_{v_0} \) is not discrete series. We remark that the case (b) of the fifth claim follows from [44] Theorem 3.3–(vi)], (see Remark 3.4 of [44]).

2. A priori, by construction, \( \rho_{\pi,t_p} \) takes values in \( \text{GL}_4(\overline{\mathbb{Q}}_p) \). However, by [3] Corollary 1.3, it factors through \( \text{GSp}_4(\overline{\mathbb{Q}}_p) \) as stated.

3. Notice \( 3 - k_1 - k_2 = -(m_1 + m_2) \). Regarding Theorem [3.1](3), if we put \( w = 0 \) and consider the twist \( \pi_v \otimes |\nu|^{-\frac{3}{2}} \otimes |\nu|^{-\frac{3}{2}} \), which yields the setting in [44].
Theorem 3.1-(vii)]. Accordingly, our Hodge-Tate weights are also shifted by \(-\delta_v\) and they give the Hodge-Tate weights in [14 Theorem 3.1-(v)].

**Definition 3.3.**

(1) Let \( \rho: G_F \rightarrow \operatorname{GSp}_4(\mathcal{O}_p) \) be a \( p \)-adic Galois representation. We say \( \rho \) is automorphic if there exists a cuspidal automorphic representation \( \pi \) of \( \operatorname{GSp}_4(\mathbb{A}_F) \) with \( \pi_v \) a (limit of) discrete series representation for any \( v|\infty \), and such that \( \rho \simeq \rho_{\pi,v} \) as a representation to \( \operatorname{GL}_4(\mathcal{O}_p) \).

(2) Let \( \overline{\rho}: G_F \rightarrow \operatorname{GSp}_4(\overline{\mathbb{F}}_p) \) be an irreducible mod \( p \) Galois representation. We say \( \overline{\rho} \) is automorphic if there exists a cuspidal automorphic representation \( \pi \) of \( \operatorname{GSp}_4(\mathbb{A}_F) \) with \( \pi_v \) a (limit of) discrete series representation for any \( v|\infty \), and such that \( \overline{\rho} \simeq \overline{\rho}_{\pi,v} \) as a representation to \( \operatorname{GL}_4(\mathbb{F}_p) \).

**Remark 3.4.** Let \( h \) be a holomorphic Hilbert–Siegel Hecke eigen cusp form on \( \operatorname{GSp}_4(\mathbb{A}_F) \) of parallel weight 2. Let \( \pi_h \) be the corresponding cuspidal automorphic representation of \( \operatorname{GSp}_4(\mathbb{A}_F) \). Then for each infinite place \( v \), the local Langlands parameter at \( v \) is given by \( \phi_{(w;1,0)} \) and \( \pi_{h,v} \) is a limit of holomorphic discrete series. Conversely, if a cuspidal automorphic representation \( \pi \) of \( \operatorname{GSp}_4(\mathbb{A}_F) \) is neither CAP nor endoscopic and its local Langlands parameter at \( v|\infty \) is given by \( \phi_{(w;1,0)} \) for some integer \( w \), one can associate such a form \( h \) by using [17]. Note that the results in [17] are conditional on the trace formula (see the second paragraph on p.472 of [17]). However, in the course of the proof of Theorem 1.1, we apply the unconditional result in [30] to construct a corresponding automorphic cuspidal representation. Hence Theorem 1.1 is true unconditionally.

### 3.2. Hilbert modular forms and the Jacquet–Langlands correspondence

We refer to [39] Section 1 and [23] Section 3 for the theory of \((p\text{-adic})\) algebraic modular forms corresponding to (paritious) Hilbert modular forms via the Jacquet–Langlands correspondence.

In this section, \( p \) is any rational prime but we remind the reader that we will later consider \( p = 2 \). Let \( M \) be a totally real field of even degree \( m \). For each finite place \( v \) of \( M \), let \( M_v \) be the completion of \( M \) at \( v \), \( \mathcal{O}_v \) its ring of integers, \( \varpi_v \) a uniformizer of \( M_v \), and \( \mathbb{F}_v \) the residue field of \( M_v \). Let \( D \) be the quaternion algebra with center \( M \) which is ramified exactly at all the infinite places of \( M \) and \( \mathcal{O}_D \) be the ring of integral quaternions of \( D \). For each finite place \( v \) of \( M \), we fix an isomorphism

\[
\iota_v: D_v := D \otimes_M M_v \simeq M_2(M_v).
\]

We view \( D^\times \) as an algebraic group over \( M \) so that for any \( M \)-algebra \( A \), \( D^\times(A) \) outputs \((D \otimes_M A)^\times\) and similarly as an algebraic group scheme over \( \mathcal{O}_M \) such that \( D^\times(R) = (\mathcal{O}_D \otimes_{\mathcal{O}_M} R)^\times \) for any \( \mathcal{O}_M \)-algebra \( R \).

Let \( K \) be a finite extension of \( \mathbb{Q}_p \) contained in \( \mathcal{O}_p \) with residue field \( k \) and ring of integers \( \mathcal{O}_K \), and assume that \( K \) contains the images of all embeddings \( M \rightarrow \mathbb{Q}_p \).

For each finite place \( v \) of \( M \) lying over \( p \), let \( \tau_v \) be a smooth representation of \( \operatorname{GL}_2(\mathcal{O}_v) \) acting on a finite free \( \mathcal{O}_K \)-module \( W_{\tau_v} \). We also view it as a representation of \( D^\times_v \) via \( \iota_v \). Put \( \tau := \otimes_v \tau_v \) which is a representation of \( \operatorname{GL}_2(\mathcal{O}_{p}) := \prod_v \operatorname{GL}_2(\mathcal{O}_v) \) acting on \( W_{\tau} := \otimes_v W_{\tau_v} \). Suppose \( \psi: M^\times \backslash (\mathcal{A}_M^\infty)^\times \rightarrow \mathcal{O}_K^\times \) is a continuous character so that for each \( \nu|p \), \( Z_{D^\times}(\mathcal{O}_v) \simeq \mathcal{O}_v^\times \) acts on \( W_{\tau_v} \) by \( \psi^{-1}|\mathcal{O}_M^\times \), where \( Z_{D^\times} \simeq \operatorname{GL}_1 \) is the center of \( D^\times \) as a group scheme over \( \mathcal{O}_M \).

Note that we put the discrete topology on \( \mathcal{O}_K^\times \) and therefore, such a character is necessarily of finite order. Let \( U := \prod_v U_v \) be a compact open subgroup of \( D^\times(\mathcal{A}_M^\infty) \simeq \operatorname{GL}_2(\mathcal{A}_M^\infty) \) such that \( U_v \subset D^\times(\mathcal{O}_{M_v}) \) for all finite places \( v \) of \( M \). Put \( U_p := \prod_v U_v \) and \( U_{(p)} := \prod_{v|p} U_v \). For any local \( \mathcal{O}_K \)-algebra \( A \) put \( W_{\tau,A} := W_{\tau} \otimes_{\mathcal{O}_K} A \). Let \( \Sigma \) be a finite set of finite places of \( M \). For each \( v \in \Sigma \), let \( \chi_v: U_v \rightarrow A^\times \) be a quasi-character. Define \( \chi_\Sigma: U \rightarrow A^\times \) whose local component is \( \chi_v \) if \( v \in \Sigma \), the trivial representation otherwise.

**Definition 3.5 \((p\text{-adic algebraic quaternionic forms})\).** Let \( S_{\tau,\psi}(U, A) \) denote the space of functions

\[
f: D^\times \backslash D^\times(\mathcal{A}_M^\infty) \rightarrow W_{\tau,A}
\]

such that
• $f(gu) = \tau(u_p)^{-1}f(g)$ for $u = (u^{(p)}, u_p) \in U^{(p)} \times U_p$ and any $g \in D^\times(A_M^{\infty})$;
• $f(zg) = \psi(z)f(g)$ for $z \in Z_{D^p}(A_M^{\infty})$ and $g \in D^\times(A_M^{\infty})$.

Similarly, let $S_{\tau,\psi,X_2}(U, A)$ denote the space of functions

$$f : D^\times \setminus D^\times(A_M^{\infty}) \to W_{\tau, A}$$

such that

• $f(gu) = \chi^{(p)}_{\psi}(u)\tau(u_p)^{-1}f(g)$ for $u = (u^{(p)}, u_p) \in U^{(p)} \times U_p$ and $g \in D^\times(A_M^{\infty})$;
• $f(zg) = \psi(z)f(g)$ for $z \in Z_{D^\times}(A_M^{\infty})$ and $g \in D^\times(A_M^{\infty})$.

We call a function belonging to these spaces a $p$-adic algebraic quaternionic form.

Let $S$ be a finite set of finite places of $M$ containing all places $v \nmid p$ such that $U_v \neq D^\times(O_v)$. We define the (formal) Hecke algebra

$$(3.2) \quad T^S_A := A[T_v, S_v]_{v \in S \cup \{v,p\}}$$

where

$$T_v = [D^\times(O_v)\iota^{-1}_v(\text{diag}(\pi_v, 1))D^\times(O_v)],$$
$$S_v = [D^\times(O_v)\iota^{-1}_v(\text{diag}(\pi_v, \pi_v))D^\times(O_v)]$$

are the usual Hecke operators. It is easy to see that both of $S_{\tau,\psi}(U, A)$ and $S_{\tau,\psi,X_2}(U, A)$ have a natural action of $T^S_A$ (cf. [13, Definition 2.2]).

Let $U = U^{(p)} \times U_p$ be as above. As explained in [39, Section 1], if we write $\text{GL}_2(A_M^{\infty}) = \prod_i D^\times t_i U Z_{D^\times}(A_M^{\infty})$, then

$$S_{\tau,\psi}(U, A) \simeq \bigoplus_i W_{T}^{(U Z_{D^\times}(A_M^{\infty}) \cap t_i^{-1}D^\times t_i)/M^\times}.$$ 

The group $(U Z_{D^\times}(A_M^{\infty}) \cap t_i^{-1}D^\times t_i)/M^\times$ is trivial for all $t$ when $U$ is sufficiently small (see [23, p.623]). Henceforth, we keep this condition until the end of the section. It follows from this that the functor $W_T \mapsto S_{\tau,\psi}(U, A)$ is exact (cf. [24, Lemma 3.1.4]).

Fix an isomorphism $\iota : \overline{\mathbb{Q}}_p \simeq \mathbb{C}$. Let

$$S_{\tau,\psi}(U, A) := \lim_{\leftarrow U^{(p)}} S_{\tau,\psi}\left(U^{(p)} \times U_p, A\right)$$

where $U^{(p)}$ tends to be small.

We consider $(k, w) = ((k_\sigma), (w_\sigma)_\sigma) \in \mathbb{Z}_{>1}^{\text{Hom}(M, \overline{\mathbb{Q}}_p)} \times \mathbb{Z}^{\text{Hom}(M, \overline{\mathbb{Q}}_p)}$ with the property that $k_\sigma + 2w_\sigma$ is independent of $\sigma$. Set $\delta := k_\sigma + 2w_\sigma - 1$ for some (any) $\sigma$. A special case we will encounter later is $(k, w) = (k \cdot 1, w \cdot 1)$ with $k \in \mathbb{Z}_{>1}$, $w \in \mathbb{Z}$, and $1 = (1, \ldots, 1) \in \mathbb{Z}^{\text{Hom}(M, \overline{\mathbb{Q}}_p)}$, where $\delta = k + 2w - 1$. Let $\psi : M^\times \rightarrow \mathbb{C}^\times$ be the character defined by

$$(3.3) \quad \psi(z) = \iota \left(N(z_p)^{\delta-1}\psi(z_\infty)\right) N(z_\infty)^{1-\delta}$$

for $z = (z_p, z_\infty) \in A_M^\times$ where the symbol $N$ stands for the norm. For each $\sigma \in \text{Hom}(M, \overline{\mathbb{Q}}_p)$, there exists a unique pair of $v|p$ and an embedding $\sigma_v : M_v \rightarrow \overline{\mathbb{Q}}_p$ such that $\sigma_v|_M = \sigma$. Therefore, we can rewrite $(\sigma_\sigma)_{\sigma \in \text{Hom}(M, \overline{\mathbb{Q}}_p)} = (\sigma_v)_{v|p, \sigma_v \in \text{Hom}(M_v, \overline{\mathbb{Q}}_p)}$.

Since $w_\sigma \in \mathbb{Z}$ for each $\sigma$, we can define the algebraic representation $\tau_{(k, w), A}$ of $\text{GL}_2(O_p) = \prod_{v|p} \text{GL}_2(O_v)$ by

$$(3.4) \quad \tau_{(k, w), A} = \bigotimes_{v|p} \bigotimes_{\sigma_v \in \text{Hom}(M_v, \overline{\mathbb{Q}}_p)} \text{Sym}^{k_{\sigma_v} - 2} \text{St}_2(A) \otimes \det^{w_{\sigma_v}} A$$

where $\text{St}_2$ is the standard representation of dimension two. We often drop the subscript $A$ from $\tau_{(k, w), A}$ which should not cause any confusion. Notice that $\tau_{(k, w), O_K} \otimes O_{K, t} \mathbb{C}$ is the algebraic
Theorem 3.6. Keep the notation as above. Suppose for some integers \( k, w \) so that the center acts by \( z \mapsto z^{\delta - 1} \), \( \delta = k_\sigma + 2w_\sigma - 1 \) for \( z \in \mathbb{C}^\times \). We write

\[
S_{k, w, \psi}(U_p, A) := S_{\tau(k, w), \psi}(U_p, A)
\]

for simplicity.

By [39 Corollary 1.2, Lemma 1.3-2], we have an isomorphism

\[
\left( S_{k, w, \psi}(U_p, \mathcal{O}_K) / S_{k, w, \psi}^{\text{triv}}(U_p, \mathcal{O}_K) \right) \otimes_{\mathcal{O}_K, \mathbf{C}} \mathbf{C} \simeq \bigoplus_{\pi} \pi_{\infty, p} \otimes \pi_p^U
\]

of \( D^\times(\mathbb{A}_\mathbb{F}^\times) \)-modules, where \( \pi \) runs over the regular algebraic cuspidal automorphic representations of \( \text{GL}_2(\mathbb{A}_\mathbb{F}) \) such that \( \pi \) has central character \( \psi_\mathbb{C} \) and \( S_{k, w, \psi}^{\text{triv}}(U_p, \mathcal{O}_K) \) is defined to be zero unless \((k, w) = (2 \cdot 1, w \cdot 1)\), in which case we define it to be the subspace of \( S_{\tau(k, w), \psi}(U_p, \mathcal{O}_K) \) consisting of functions that factor through the reduced norm of \( D^\times(\mathbb{A}_\mathbb{F}) \).

For \( \tau(k, w, \mathbb{C}) \) as above we can also consider the space of Hilbert cusp forms on \( \text{GL}_2(\mathbb{A}_\mathbb{F}) \) of level \( U \) and of weight \( (k, w) \) and their geometric counterparts (see [14 Section 1.5]). Thanks to many contributors (see [20] and the references there), to each (adelic) Hilbert Hecke eigenform \( f \) of weight \( (k, w) \) and level \( U \), one can attach an irreducible \( p \)-adic Galois representation \( \rho_{f, p} : G_{\mathbb{F}} \rightarrow \text{GL}_2(\mathbb{Q}_p) \) for any rational prime \( p \) and fixed isomorphism \( \mathbb{Q}_p \cong \mathbb{C} \). The construction also works for \( k \geq 1 \) (in the geometric order). In particular, in the case when \( k = 1 \) (parallel weight one), its image is finite and it gives rise to an Artin representation \( \rho_f : G_{\mathbb{F}} \rightarrow \text{GL}_2(\mathbb{C}) \) (see [31]). Taking a suitable integral lattice, we consider the reduction \( \overline{\rho}_{f, p} : G_{\mathbb{F}} \rightarrow \text{GL}_2(\mathbb{F}_p) \) of \( \rho_{f, p} \) or \( \rho_f \) modulo the maximal ideal of \( \mathbb{Z}_p \).

Let \( F \) be a totally real subfield of \( M \) such that \([M : F] = 2\). This is possible since \( M/\mathbb{Q} \) is a Galois extension of even degree. Let \( s \) be the generator of \( \text{Gal}(M/\mathbb{F}) \). Put \( S_M := \text{Hom}_\mathbb{Q}(M, \mathbb{C}) \) and let \( S_M^{(1)} \) be a subset such that \( S_M = S_M^{(1)} \bigcup S_M^{(2)} \) where \( S_M^{(2)} := S_M^{(1)} \circ s \). Further, we identify \( S_M^{(1)} \) with \( S_F = \text{Hom}_\mathbb{Q}(F, \mathbb{C}) \) via \( \sigma \mapsto \sigma|_F \).

Let *f be the twist of \( f \) by \( s \) which is defined by the composition of \( f \) and the automorphism of \( D^\times(\mathbb{A}_\mathbb{F}) \) induced from \( s \). We denote by \( \omega f, \mathbb{C} \) the central character, which satisfies \( \omega f = \omega f \). Let \( \overline{\pi}_f \) (resp. \( \overline{\pi}, \mathbb{C} \)) be the corresponding cuspidal representation attached to \( f \) (resp. \( *f \)).

Changing the subset \( S_M^{(1)} \) if necessary, we may write \( k = (k_\tau)_{\tau \in S_M} \) as \( k = (k_1, k_2)_{\sigma \in S_M^{(1)}} \) with \( k_1, \sigma \geq k_2, \sigma \) for each \( \sigma \in S_M^{(1)} \), where \( k_\tau = k_1, \tau \) if \( \tau \in S_M^{(1)} \) and \( k_\tau = k_2, \tau \) if \( \tau = \sigma \circ s \). \( S_M^{(2)} \).

Applying [30, 31, 36], we have the following unconditional theorem:

**Theorem 3.6.** Keep the notation as above. Suppose \( k = (k_1, 1, k_2, 1) \) is in \( \mathbb{Z} S_M^{(1)} \times \mathbb{Z} S_M^{(2)} \) for some integers \( k_1 \geq k_2 \geq 2 \) with \( k_1 \equiv k_2 \mod 2 \). For each \( \sigma \in S_M^{(1)} \), put \( w_\sigma = 0 \) and \( w_{f, \sigma} = k_1 - k_2 \). Further, suppose \( \pi_f \) is not isomorphic to \( \pi_f \) (equivalently, \( f \) does not come from any Hilbert cusp form on \( \text{GL}_2(\mathbb{A}_\mathbb{F}) \) via base change) and suppose the central character \( \omega f \) satisfies \( \omega f = \omega f \). Then, there exists a Hilbert–Siegel Hecke eigen cusp form \( h \) on \( \text{GSp}_4(\mathbb{A}_\mathbb{F}) \) such that the corresponding cuspidal automorphic representation \( \Pi = \Pi_\mathbb{F} \) satisfies the following:

1. For each infinite place \( v \in S_F \) and \( \sigma \in S_M^{(1)} \) such that \( \sigma|_F = v \), the L-parameter of \( \Pi_v \) is given by \( \phi_{(k_1, \sigma : m_1, \sigma ; m_2, \sigma)} \otimes | \cdot | \) with
   \[
m_1, \sigma = \frac{k_1, \sigma + k_2, \sigma - 2}{2}, \quad m_2, \sigma = \frac{k_1, \sigma - k_2, \sigma}{2};
   \]

2. For each \( p \) and \( \ell_p \), there exists an irreducible \( p \)-adic Galois representation \( \rho_{h, \ell_p} : G_{\ell_p} \rightarrow \text{GSp}_4(\mathbb{Q}_p) \) enjoying the following properties:
   a. \( \rho_{h, \ell_p} = \text{Ind}_{G_{\mathbb{F}_p}}^{G_{\mathbb{F}}(\ell_p)} \rho_{f, \ell_p} \);
   b. \( \rho_{h, \ell_p} \) satisfies (1), (2), (3) of Theorem 3.1;
   c. For each finite place \( v \) of \( F \) dividing \( p \), \( \rho_{h, \ell_p}|_{\mathbb{F}_v} \) is de Rham and it satisfies the local-global compatibility up to Frobenius semi-simplification. Further, it has the Hodge–Tate weights as in (4) of Theorem 3.1.
Proposition 3.8. Let \( h \) happens to the central characters in the process of the congruence method. Well-known to experts but we give the details for completeness; we also look carefully at what Hilbert modular forms and any finite places by \([36, \text{Theorem 1}]\).

Remark 3.7. Theorem 3.1. The claim (2)-(a) follows from the matching of the Satake parameters at unramified correspondence, we have a 2-adic algebraic quaternionic form \( h \).

Proof. Let \( M \) be a sufficiently small open compact subgroup of \( \text{GL}_2(A_M) \) that fixes \( f \). Since \( f \) is of parallel weight one, we have \( (k, \omega) = (1, w \cdot 1) \) for some \( w \in \mathbb{Z} \). By twisting if necessary, we may assume \( w = 0 \). Let \( K \) be a finite extension of \( \mathbb{Q}_2 \) in \( \mathbb{Q}_2 \) with ring of integers \( \mathcal{O}_K \) such that \( K \) contains all Hecke eigenvalues of \( f \) for \( \mathcal{T}^0_{\mathcal{O}_K} \). Let \( F \) be the residue field of \( K \). As in \([14, \text{Section 1.5}]\), we can view \( f \) as a geometric Hilbert modular form over \( \mathcal{O}_K \) via a classical Hilbert modular form associated to \( f \) and consider its base change \( \overline{f} \) to \( F \). After multiplying by a high enough power of the Hasse invariant, we have another form \( \overline{g}_1 \) of weight \((k, 0)\) with \( k = k \cdot 1, k \gg 0 \) such that

1. \( \overline{g}_{1,\overline{g}_1} \cong \overline{g}_{1,\overline{g}_1} \otimes \overline{\psi} \) for some continuous character \( \psi: G_M \rightarrow \mathbb{F}_2^\times \).

2. The character corresponding to the central character of \( g \) under \([3,3]\) is trivial;

3. \( g \) is of weight \((2, 0)\) with 2 := 2 \cdot 1 (parallel weight 2). Here we write \( 0 = (0, \ldots, 0) \in \mathbb{Z}^n \).

Further, if \( \text{det}(\overline{g}_{1,\overline{g}_1}) \) is trivial, then \( \psi \) can be taken to be trivial.

Proof. Let \( U \) be a sufficiently small open compact subgroup of \( \text{GL}_2(A_M) \) that fixes \( f \). Since \( f \) is of parallel weight one, we have \( (k, \omega) = (1, w \cdot 1) \) for some \( w \in \mathbb{Z} \). By twisting if necessary, we may assume \( w = 0 \). Let \( K \) be a finite extension of \( \mathbb{Q}_2 \) in \( \mathbb{Q}_2 \) with ring of integers \( \mathcal{O}_K \) such that \( K \) contains all Hecke eigenvalues of \( f \) for \( \mathcal{T}^0_{\mathcal{O}_K} \). Let \( F \) be the residue field of \( K \). As in \([14, \text{Section 1.5}]\), we can view \( f \) as a geometric Hilbert modular form over \( \mathcal{O}_K \) via a classical Hilbert modular form associated to \( f \) and consider its base change \( \overline{f} \) to \( F \). After multiplying by a high enough power of the Hasse invariant, we have another form \( \overline{g}_1 \) of weight \((k, 0)\) with \( k = k \cdot 1, k \gg 0 \) such that

1. \( \overline{g}_1 \cong \overline{g}_{1,\overline{g}_1} \);

2. \( \overline{g}_1 \) is liftable to a geometric Hilbert Hecke eigenform \( g_1 \) over \( \mathcal{O}_K \) by enlarging \( K \) if necessary;

3. \( \overline{g}_{1,\overline{g}_1} \cong \overline{g}_{1,\overline{g}_1} \).

We view \( g_1 \) as a classical Hilbert Hecke eigen cusp form and by the Jacquet–Langlands correspondence, we have a 2-adic algebraic quaternionic form \( h_1 \) in \( S_\mathcal{O}_K \psi(U, \mathcal{O}_K) \) corresponding to \( g_1 \); here \( \psi: \mathcal{M} \times \mathcal{A}_M \rightarrow \mathcal{O}_K \) is the finite character corresponding to the central character of \( g_1 \) under \([3,3]\). For each finite place \( v \) of \( M \) lying over 2, let \( U_{1,v} \) be the subgroup of \( U_v \) consisting of all elements congruent to \( \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \). Put \( U_{1,2} := \prod_{v

We are looking for monic irreducible polynomials \( f \in \mathbb{Q}[x] \) of degree 6 such that

1. there is an isomorphism \( \sigma \) from the Galois group of \( f \) to the symmetric group \( S_5 \);
2. for any complex conjugation \( c \) in the Galois group of \( f \), the element \( \sigma(c) \in S_5 \) has type \((2, 2)\).
We shall give two families of such polynomials. A general approach to produce them is to compute the sextic resolvent polynomial \( f \) of an irreducible quintic polynomial over \( F \) with Galois group \( S_5 \). This can be done using symbolic computation, in a straightforward but very tedious way; also, writing down an explicit form would take considerable space. To get around this, we apply classical results of Hermite and Klein.

4.1. Using generic polynomials. Let \( F = \mathbb{Q} \). Hermite proved that the polynomial \( P \in \mathbb{Q}(s,t)[x] \) given by

\[
P(x) = x^5 + sx^3 + tx + t
\]
is generic for \( S_5 \), which means that every \( S_5 \)-extension \( K/\mathbb{Q} \) is the splitting field of some specialization of \( P \), and that the splitting field of \( P \) has Galois group \( S_5 \) over \( \mathbb{Q}(s,t) \). A proof appears in [21 Proposition 2.3.8]. The discussion in Section 2.4 of the same book contains the following observation: If \( h \in \mathbb{Q}[x] \) is a quintic polynomial with Galois group \( S_5 \), then the Weber sextic resolvent of \( h \) is an irreducible sextic with the same splitting field, corresponding to the transitive embedding of \( S_5 \) into \( S_6 \). We can apply this to a specialization \( h \) of \( P \) with \( s, t \in \mathbb{Q} \), and get the Weber sextic resolvent

\[
f(x) = (x^3 + b_4x^2 + b_2x + b_0)^2 - 2^{10}\text{disc}(h)x,
\]
where \text{disc}(h) is the discriminant of \( h \) and the coefficients are given by

\[
b_0 = -176s^2t^2 + 28s^4t + 4000st^2 - s^6 + 320t^3,
\]
\[
b_2 = 3s^4 - 8s^2t + 240t^2,
\]
\[
b_4 = -3s^2 - 20t.
\]

Taking different rational values of \( s \) and \( t \), we can obtain lots of examples of \( f \) with property (1) above.

Property (2) is easy to verify once \( s \) and \( t \) are given, as it is equivalent to \( h \) having a unique real root. We determine the relation between the values of \( s \) and \( t \) and the number of real roots of \( h \) using Sturm’s Theorem [2 Theorem 2.62], which requires computing the Sturm sequence

\[
h_0(x) = h(x) = x^5 + sx^3 + tx + t
\]
\[
h_1(x) = h'(x) = 5x^4 + 3sx^2 + t
\]
\[
h_2(x) = -(h_0(x) \mod h_1(x)) = -\frac{2}{5}sx^3 - \frac{4}{5}tx - t
\]
\[
h_3(x) = -(h_1(x) \mod h_2(x)) = \frac{g_3}{s}x^2 + \frac{25t}{2s}x - t
\]
\[
h_4(x) = -(h_2(x) \mod h_3(x)) = \frac{tg_4}{2g_3}x + \frac{t(5t - s^2)(20t - 9s^2)}{g_3^2}
\]
\[
h_5(x) = -(h_3(x) \mod h_4(x)) = \frac{g_5g_5}{g_4},
\]
where \( a(x) \mod b(x) \) denotes the remainder of the polynomial division of \( a(x) \) by \( b(x) \), and for future use we define

\[
g_3(s,t) = 10t - 3s^2
\]
\[
g_4(s,t) = 12s^4 - 88s^3t + 125st + 160t^2
\]
\[
g_5(s,t) = 108s^5 + 16s^4t - 900st^4t - 12s^2t^2 + 2000st^2 + 256t^3 + 3125t^2.
\]

Given a polynomial \( p \) of degree \( n \) in \( x \) with leading coefficient \( a_n \), we define the sign of \( p \) at \( +\infty \) to be the sign of \( a_n \), and the sign of \( p \) at \( -\infty \) to be \((-1)^n\) times the sign of \( a_n \). For the Sturm sequence \( h_0, h_1, \ldots, h_5 \), we write \( V(-\infty) \) for the number of sign changes in the sequence of signs at \( -\infty \), and \( V(+\infty) \) for the number of sign changes in the sequence of signs at \( +\infty \). Sturm’s Theorem then says that the number \( r \) of real roots of \( h \) is given by

\[
r = V(-\infty) - V(\infty).
\]
We gather some observations that will simplify our analysis:

1. If $s < 0$ then $g_3(s, t) < 0$: clear as it is a sum of negative terms.
2. If $s < 0$ and $t < 0$ then $g_4(s, t) > 0$: clear as it is a sum of positive terms.
3. If $s > 0$ and $t > 0$ then $g_5(s, t) > 0$. This follows from completing a couple of squares to rewrite:

$$g_5(s, t) = 3s(6s^2 - 25t)^2 + 16t(s^2 - 4t)^2 + 125st^2 + 3125t^2.$$ 

4. If $s > 0$, $t > 0$, and $g_3(s, t) > 0$ then $g_4(s, t) > 0$. To see this, note that

$$g_4(s, t) = \frac{4}{3} g_3^2(s, t) + \frac{8}{3} t g_3(s, t) + 125st.$$ 

5. If $s > 0$, $t < 0$, and $g_4(s, t) < 0$, then $g_5(s, t) > 0$. This follows from

$$g_5(s, t) = \frac{8}{5} g_4(s, t)t + 108s^5 - t \left( \frac{16}{5} s^4 + 900s^3 \right) + t^2 \left( \frac{64}{5} s^2 + 1800s + 3125 \right).$$ 

6. If $s < 0$, $t > 0$, $g_3(s, t) > 0$ and $g_4(s, t) > 0$, then $g_5(s, t) > 0$. This follows implicitly from Sturm’s Theorem: if $g_5(s, t) < 0$ then the sign sequence at $-\infty$ is $-++----$, and the sign sequence at $+\infty$ is $+++++$, hence the quantity $V(-\infty) - V(\infty) = -1$.

Table 1 gives the number $r$ of real zeros of $h(x)$ in relation to the signs of the various relevant quantities. We have used the observations made above to reduce the number of possibilities from $2^{5} = 32$ to 15:

| $s$  | $t$  | $g_3$ | $g_4$ | $g_5$ | signs at $-\infty$ | $V(-\infty)$ | signs at $+\infty$ | $V(+\infty)$ | $r$ |
|------|------|-------|-------|-------|---------------------|-------------|---------------------|-------------|-----|
| +    | +    | +     | +     | +     | ++++-----            | 3           | +++-+++             | 2           | 1   |
| +    | +    | +     | +     | -     | +--+-+---            | 3           | ++++---             | 2           | 1   |
| +    | +    | -     | -     | +     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | -     | -     | -     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | +     | +     | -     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | +     | -     | +     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | -     | +     | -     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | -     | +     | +     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | +     | -     | +     | +--+-+---            | 3           | ++-++---            | 2           | 1   |
| -    | +    | +     | -     | +     | +--+-+---            | 3           | ++-++---            | 2           | 1   |

Table 1. Details of the inputs to Sturm’s Theorem, depending on the possible signs of $s$, $t$, $g_3(s, t)$. The output of Sturm’s Theorem, the number $r$ of real roots of the polynomial $h$, appears in the rightmost column.

We can summarize the findings in Table 1 as follows:

**Proposition 4.1.** The polynomial $h(x) = x^5 + sx^3 + tx + t$ has exactly 3 real roots if and only if $g_5(s, t) < 0$. If $g_5(s, t) > 0$, then $h$ has exactly 5 real roots if and only if $s < 0$, $t > 0$, $g_3(s, t) < 0$, and $g_4(s, t) > 0$. 

13
The complement of the conditions listed in the Proposition gives the region in the \((s, t)\)-plane of interest to us, namely that where \(h\) has exactly one real root. We note that this occurs everywhere in the first quadrant, and almost nowhere in the third quadrant. The behaviour in the second quadrant is by far the most interesting, as can be seen in Figure 1.

![Figure 1](image)

**Figure 1.** Second quadrant (left) and entire \((s, t)\)-plane (right): blue (resp. yellow, green) points represent polynomials \(h\) having precisely 1 real root (resp. 3, 5 real roots). The boundaries of these regions are given by the black curve \(g_5(s, t) = 0\).

4.2. **Using 5-torsion on elliptic curves.** Next we consider the quintic polynomials arising from 5-division points of elliptic curves. This has the advantage that an explicit form of the resolvent is well-known: it goes back to work of Klein. Almost everything that follows is described in [19].

Let \(F\) be a totally real field not containing \(\sqrt{5}\). Let

\[
E: \quad y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6
\]

be an elliptic curve over \(F\) with the property that the mod 5 representation \(\rho_{E,5}: G_F \rightarrow \text{GL}_2(\mathbb{F}_5)\) is full\(^1\) hence surjective. The projective image of \(\rho_{E,5}\) is \(\text{PGL}_2(\mathbb{F}_5)\), which is isomorphic to \(S_5\). In fact, the faithful action of \(\text{PGL}_2(\mathbb{F}_5)\) on the projective line \(\mathbb{P}^1(\mathbb{F}_5)\) by fractional linear transformations yields \(\text{PGL}_2(\mathbb{F}_5) \hookrightarrow \text{Aut}(\mathbb{P}^1(\mathbb{F}_5)) \cong S_6\). Since \(|\text{PGL}_2(\mathbb{F}_5)| = 120\), by the classification of the subgroups of \(S_6\) (cf. GAP), \(\text{PGL}_2(\mathbb{F}_5)\) is isomorphic to \(S_5\). Further, there are no fixed points in this action, hence the image of \(\text{PGL}_2(\mathbb{F}_5)\) is a transitive subgroup of \(S_6\).

Under this identification, for each complex conjugation \(c\), \(\rho_{E,p}(c) \sim \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\) corresponds to an element of \(S_6\) of type \((2, 2)\).

The corresponding \(S_5\)-extension of \(F\) is described by a quintic polynomial

\[
\theta_{E,5}(x) = x^5 - 40\Delta x^2 - 5c_4\Delta x - c_4^2\Delta,
\]

(see [19 Equation (1.24)]) where the invariants \(\Delta, c_4\) are defined in [35 §III.1, p.42]. The resolvent of \(\theta_{E,5}\) is computed as in [19 Equation (2.37)] in conjunction with [25 Proposition 3.2.1] and it is explicitly given by

\[
f_{E,6}(x) := x^6 + b_2x^5 + 10b_4x^4 + 40b_6x^3 + 80b_8x^2 + 16(b_2b_8 - b_4b_6)x + (-b_2b_4b_6 + b_2^2b_8 - 5b_6^2),
\]

where \(b_2, b_4, b_6, b_8\) are also defined in [35 §III.1, p.42]. The Galois group of the splitting field \(F_{f_{E,6}}\) of \(f_{E,6}(x)\) over \(F\) in \(\overline{\mathbb{Q}}\) is a priori embedded in \(S_6\) by permuting the roots but it is isomorphic to \(S_5\) since \(F_{f_{E,6}} = F_{\theta_{E,5}}\) by construction. Let us consider the hyperelliptic curve

\(\footnote{We say that \(\rho_{E,p}\) is full if \(\text{End}_F(E) = \mathbb{Z}\) and the image of \(\rho_{E,p}\) contains \(\text{SL}_2(F_p)\).}
\( C = C_E \) defined by \( y^2 = f_{E,6}(x) \). The above argument gives a natural embedding of \( \text{Im}(\rho_{C,2}) \) into \( S_6 \). It is well-known that \( \rho_{E,5} \) is totally odd and it shows that \( \rho_{C,2}(c) \) is of type \((2,2)\) for each complex conjugation of \( G_F \). Further, if \( f_{E,6}(x) \) is irreducible, then \( \text{Im}(\rho_{C,2}) \) is transitive in \( S_6 \) and hence is of type \( S_5(a) \). Summing up, we have

**Theorem 4.2.** Assume that \( \rho_{E,5} \) is full and \( f_{E,6} \) is irreducible. Then \( \rho_{C,E,2} \) is automorphic in the sense of Theorem [7,4].

We illustrate the method with some explicit examples.

- Let us consider the elliptic curve \( E : y^2 + y = x^3 + x^2 \) over \( \mathbb{Q} \), of conductor 43. By [26, Elliptic curve with label 43.a1], the representation \( \rho_{E,5} : G_Q \to \text{GL}_2(\mathbb{F}_5) \) is full. On the other hand, we have \( \theta_{E,5} = x^5 + 1720x^2 + 3440x + 11008 \) and it is easy to check (e.g. using SageMath [10] or Magma [6]) that

\[
(4.1) \quad f_{E,6}(x) = x^6 + 4x^5 + 40x^3 + 80x^2 + 64x + 11
\]

is irreducible over \( \mathbb{Q} \) with Galois group isomorphic to \( S_5 \). By Theorem 4.2, \( \rho_{C,E,2} \) is automorphic.

- For an example where the ground field is not \( \mathbb{Q} \), consider \( E : y^2 = x^3 - x^2 + x \) over \( F = \mathbb{Q}(\sqrt{2}) \), see [26, Elliptic curve 72.1-a3 over number field \( \mathbb{Q}(\sqrt{2}) \)]. Once more, \( \rho_{E,5} \) is full and the resolvent \( f_{E,6}(x) = x^6 + 4x^5 + 20x^4 - 80x^2 - 64x - 16 \) is irreducible over \( F \), so we conclude that \( \rho_{C,E,2} \) is automorphic.

### 4.3. Databases of genus 2 curves.

The methods used in §4.1 and §4.2 produce infinite families of examples satisfying the conditions of Theorem [1.1], but they tend to give hyperelliptic curves with large conductors. For instance, the conductor of the curve (4.1) is

\[ 4786321400000 = 2^6 \cdot 5^5 \cdot 7 \cdot 43^4 \]

and the curve corresponding to the choice of parameters \( s = 0, t = -1 \) in [4.1] has equation

\[
y^2 = x^6 + 40x^5 + 880x^4 + 8960x^3 + 44800x^2 - 3091456x + 102400
\]

and conductor

\[ 823116100000 = 2^4 \cdot 5^4 \cdot 19^2 \cdot 151^2 \]

There are however databases of genus 2 curves with conductor that is either small or has restricted prime factors. Currently the most comprehensive are based on [5], which produced:

- 66158 curves with conductor less than 1000000, to be found at [26, Genus 2 curves over \( \mathbb{Q} \)]; from this list, we verified that the curves labelled

\[
50000.b.800000.1 \quad 378125.a.378125.1 \quad 681472.a.681472.1 \\
64800.c.648000.1 \quad 382347.a.382347.1 \quad 703125.b.703125.1 \\
180625.a.903125.1 \quad 506763.a.506763.1
\]

satisfy the conditions of Theorem [1.1]

- 487493 curves with 5-smooth discriminant, to be found at [38]; we verified that 4885 of these curves satisfy the conditions of Theorem [1.1]

Both databases provide the curves as global minimal models described by equations of the form \( y^2 + h(x)y = f(x) \).
