ABSTRACT

Background: Clips are commonly used to divide vessels in laparoscopic surgery. However, branches of the superior mesenteric vein (SMV), including the superior right colic vein (SRCV), are narrow, and the clips are too large to be used for these veins. During surgery, there is concern about the risk of bleeding due to vascular injury, as well as when detaching the clips after the procedure.

Patients and Methods: From January 2014 to December 2016, six patients with right side transverse colon cancer underwent clipless laparoscopic surgery were enrolled in this study. After skeletonizing around the roots of the SRCVs, they were divided at their roots only by LigaSure, without the use of clips.

Results: The mean operative time was 136 min (range 114-160), the mean operative blood loss was less than 10 ml, and no bleeding at the stump of the SRCV was confirmed during surgery. The mean length of hospitalization after surgery was 10 days, and no complications were encountered after surgery. No recurrence was found more than three years after surgery.

Conclusion: Clipless laparoscopic division of the SRCV is a useful procedure for patients with right side transverse colon cancer.

Key words: clipless laparoscopic surgery, partial transverse colectomy, LigaSure

INTRODUCTION

Currently, laparoscopic surgery is applied for the treatment of a variety of diseases. Here, we report total colectomy via a clipless laparoscopic surgical procedure with a single incision (1). There are few reports on clipless laparoscopic partial colectomy for patients with right side transverse colon cancer. Clips are commonly used to divide vessels in laparoscopic surgery. However, the branches of the superior mesenteric vein (SMV), including the superior right colic vein (SRCV), are narrow, and the clips are too large to be used for these veins. During surgery, there is concern about the risk of bleeding due to vascular injury, as well as when detaching the clips after the procedure; a clipless procedure reduces these concerns. We performed a novel procedure: a clipless laparoscopic partial colectomy for right side transverse colon cancer.
MATERIALS AND METHODS

From January 2014 to December 2016, six patients with right side transverse colon cancer underwent clipless laparoscopic surgery, were retrospectively registered. The cohort consisted of two patients with stage I and four patients with stage III colon cancer (table 1). In this procedure, dissection around the vessels was performed only with a sealing device, LigaSure, without the use of clips. SRCV, the middle colic vein (MCV), and the middle colic artery (MCA) were also divided at their roots only by LigaSure, without the use of clips.

The Ethics Committee for Biomedical Research of the Jikei Institutional Review Board approved the protocol [30-344 (9365)], and all patients or their family members provided written informed consent to participate.

SURGICAL TECHNIQUES

First, the greater omentum was divided by an approach with five ports. Then, the division was extended laterally to hepatic flexures of the colon. A window in the mesocolon was created from the descending to the horizontal portion of the duodenum. The SRCV, located on the patients’ left side of the window, was detected and skeletonized around its root (fig. 1). After the skeletonizing, they were divided at their root by a single sealing of LigaSure without clips (fig. 2). After a partial transverse colectomy following the dissection of the middle colic vein and colic artery, intestinal reconstruction was performed with a stapler to create a functional end-to-end anastomosis.

RESULTS

The mean operative time was 136 min (range 114-160), the mean operative blood loss was less than 10 ml, and no bleeding at the stump of the SRCV were confirmed during surgery. The mean length of hospitalization after surgery was 10 days, and no complications were encountered after surgery. No recurrence was found more than three years after surgery.

DISCUSSION

The risk of bleeding in the SMV during laparoscopic right hemicolecction or partial transverse colectomy has increased since the introduction of D3 lymph node dissection (2). The main cause of bleeding is the
laparoscopic dissection of the gastrocolic trunk of Henle (3). Many variations have been identified in the formation and drainage routes of other venous colic tributaries of the SMV (4). In a right hemicolectomy and partial transverse colectomy for patients with colon cancer, these vessels are divided at their roots with D3 lymph node dissection (5-7). Clips have been commonly used to divide vessels in laparoscopic surgery. However, the branches of the SMV, including the SRCV, are narrow, and the clips are too large for these veins. During surgery, there is concern about the risk of bleeding due to vascular injury, as well as when detaching the clips after the procedure.

We reported total colectomy via a clipless laparoscopic surgical procedure with a single incision surgery (1). In this procedure, the MCA and MCV were divided slightly away from their roots by a double sealing of LigaSure with incomplete skeletonization around them. No bleeding was confirmed at the stumps of vessels. In the present study, the MCA and MCV were divided at their roots by a double sealing of LigaSure with complete skeletonization around their roots. Branches of the SMV, including the SRCV, were divided at their roots by a single sealing of LigaSure. No bleeding was confirmed at the stumps of vessels.

The division of vessels with clips requires a long length of skeletonized vessels because vessels have to be divided between the proximal and distal clips. Since clipless vascular division requires a shorter length of skeletonized vessels compared to those needed for the procedure with clips, clipless vascular division seems feasible and safe.

Clipless laparoscopic surgery is actively applied for cholecystectomy however there are few reports on clipless laparoscopic colectomy for patients with colorectal diseases (8-10).

Long-term follow-up and large-scale evaluation are necessary, but clipless laparoscopic surgery seems to be a useful procedure for patients with right side transverse colon cancer.

**Ethics approval and consent to participate**

The Ethics Committee for Biomedical Research of the Jikei Institutional Review Board approved the protocol [30-344 (9365)], and all patients or their family members provided written informed consent to participate.

**Consent for publication**

The written consent to publish images or other personal or clinical details of participants was obtained from the patient.

**Availability of data and materials**

All data generated or analysed during this study are included in this published article.

**Competing interests**

The authors declare no competing interests.
