Abstract

Silencing of genes through RNA interference (RNAi) in insects has gained momentum during the past few years. RNAi has been used to cause insect mortality, inhibit insect growth, increase insecticide susceptibility, and prevent the development of insecticide resistance. We investigated the efficacy of topically applied dsRNA to induce RNAi for five Cytochrome P450 genes family 4 (CYP4) in *Diaphorina citri*. We previously reported that these CYP4 genes are associated with the development of insecticide resistance in *D. citri*. We targeted five CYP4 genes that share a consensus sequence with one dsRNA construct. Quantitative PCR confirmed suppressed expression of the five CYP4 genes as a result of dsRNA topically applied to the thoracic region of *D. citri* when compared to the expression levels in a control group. Western blot analysis indicated a reduced signal of cytochrome P450 proteins (45 kDa) in adult *D. citri* treated with the dsRNA. In addition, oxidase activity and insecticide resistance were reduced for *D. citri* treated with dsRNA that targeted specific CYP4 genes. Mortality was significantly higher in adults treated with dsRNA than in adults treated with water. Our results indicate that topically applied dsRNA can penetrate the cuticle of *D. citri* and induce RNAi. These results broaden the scope of RNAi as a mechanism to manage pests by targeting a broad range of genes. The results also support the application of RNAi as a viable tool to overcome insecticide resistance development in *D. citri* populations. However, further research is needed to develop grower-friendly delivery systems for the application of dsRNA under field conditions. Considering the high specificity of dsRNA, this tool can also be used for management of *D. citri* by targeting physiologically critical genes involved in growth and development.

References

[1] Anti-sense RNA strand transcription has been used for over three decades to inhibit gene activity [3]. The efficacy of anti-sense silencing depends on hybridization between the injected RNA and an endogenous messenger. Since the discovery of double-stranded RNA (dsRNA) mediated gene-specific silencing in the nematode, *Caenorhabditis elegans* (Maupas) [4], dsRNA-mediated RNAi has been employed with various insects to silence specific genes [2]. RNAi has been widely used in various insect orders, including Coleoptera, Diptera, Hemiptera, Hymenoptera, Isoptera, Lepidoptera, Neuroptera, and Orthoptera [5,6,7]. The systemic nature of dsRNA-mediated RNAi has allowed this tool to be used in the management of various insect pests [8–13].

The cytochrome P450 monoxygenases are an important group of enzymes that are involved in the metabolism of xenobiotic compounds in insects. This group of enzymes is associated with insecticide resistance and metabolism of a wide range of endogenous and exogenous compounds that includes hormones, pheromones, insecticides, and plant secondary compounds in insects [14–18]. Overtranscription of families 4, 6, 9, and 12 has been frequently linked to insecticide metabolism and resistance [19–22].

The Asian citrus psyllid, *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae), is perhaps the most destructive pest of citrus, mainly because it is a vector for the putative causal agent of huanglongbing (HLB), *Candidatus Liberibacter asiaticus* (CLas) [23]. HLB is a deadly citrus disease with no known cure [23,24]. Currently, the main tools that limit the spread of the disease are insecticides to manage the vector [18,25,26]. *D. citri* are susceptible to several insecticide classes, which includes the pyrethroids, organophosphates, carbamates, neonicotinoids, insect growth regulators, horticultural oils, and lipid synthesis inhibitors [27]. Foliar treatments may suppress populations for 3 weeks following application [27]. Broad-spectrum insecticides (pyrethroids, organophosphates, and neonicotinoids) are more effective against *D. citri* than IGRs or oils, and insecticide use against *D. citri* is most effective when populations are not actively reproducing.

ing [28]. Systemic soil-applied insecticides provide a much longer duration of population control (months) than foliar insecticides (weeks) [27]. The neonicotinoids have been the main class of effective systemic insecticides for *D. citri* control during the past decade [27]. Systemic neonicotinoids are particularly effective in protecting young trees as they mature into production [29].

Intense insecticide use has led to the development of varying levels of insecticide resistance in populations of *D. citri* in Florida, USA [26]. This is particularly concerning for the neonicotinoid class, since these are the main current tools for protecting young trees from CLas infection [29]. A metabolic mechanism for the evolution of insecticide resistance in populations of *D. citri*, particularly for neonicotinoids, is supported by increased activities of detoxifying enzymes and overexpression of Cytochrome P450 genes family 4 (CYP4) [17,21,26,30,31]. In the present study, we targeted the abovementioned CYP4 genes for silencing by topical application of specific dsRNA to the thorax of newly emerged *D. citri* adults. Additionally, we tested the effect of dsRNA treatment on insecticide resistance by comparing mortality of known susceptible and resistant populations of *D. citri*.

**Materials and Methods**

**Insect populations**

A laboratory susceptible population (LS) of *D. citri* was maintained in a greenhouse at the Citrus Research and Education Center, Lake Alfred, Florida. The culture was established in 2000 using field populations from Polk County, Florida and maintained on sweet orange (*Citrus sinensis* (L.) Osbeck) without exposure to insecticides in a greenhouse at 27–28°C, with 60–65% relative humidity and a 14:10 (light:dark) photocycle hours. Three field populations of *D. citri* were collected from commercial citrus groves in Florida during 2013. The populations were collected with permissions from private groves. Name of groves, counties, and GPS coordinates are as the following: i) GapWay Groves (Private managed grove), Polk County (FL) (28° 05’ 40.14” N, 81° 43’ 19.03” W); ii) Winter Garden, Conserve II (Private managed grove), Lake County (LA) (28° 27’ 52.17” N, 81° 39’ 31.69” W); and iii) Uncle Matt’s Organic (Organically managed grove), Lake County (OG) (28° 31’ 00.86” N, 81° 40’ 01.90” W). Adults were collected using sweep nets and aspirators, transferred to the laboratory, released onto citrus plants within Plexiglas cages (40×40×40 cm), and used in bioassays shortly thereafter.

**Constructing dsRNA**

A consensus sequence, derived from five previously published CYP4 sequences [21], was used to design CYP4-specific primers (Table 1). The CYP4-specific primers were tailed with a T7 promoter sequence to generate sense and antisense transcripts separately.

Total RNA isolation was performed on groups of 40–50 psyllids using the SV total RNA isolation kit (Promega, Madison, WI, USA). One microgram of RNA was used to synthesize cDNA using the CYP4-specific reverse primers and iScript cDNA synthesis kit (Bio-Rad, Hercules, CA, USA). Sense and antisense PCR products were generated in separate PCR reaction using specific combination of primers (Table 1). To generate plus-sense

D. citri treatment with dsRNA

Purified dsRNA was serially diluted using RNase-free water to obtain desired concentrations of dsRNA. Three concentrations of dsRNA [50, 75, and 100 ng/μl] and a control (0 ng/μl) were used to treat D. citri adults. D. citri adults were anaesthetized under CO₂ within a few hours of eclosion. A 0.2 μl droplet containing 10, 15, or 20 ng of dsRNA was topically applied to the ventral side of the thorax using a 10 μl Hamilton syringe. To investigate the effect of dsRNA- P₄₅₀ on gene and protein expression and enzymatic activity, treated adults were placed into 60 mm plastic disposable Petri dishes that were lined with citrus leaf disks, as a food source, over agar beds as described in Tiwari et al. [17]. Petri dishes with treated adults were kept at 25±1°C and 50±5% RH, with a 14:10 h light:dark photoperiod, in a growth chamber for 72 h. Insects were collected and stored in −20°C until use. dsRNA-gfp was used as a non-relevant dsRNA control.

Cytochrome P₄₅₀ (general oxidase) assay

The activity of cytochrome P₄₅₀ was quantified and expressed in terms of general oxidase level, which is an indirect measure of cytochrome P₄₅₀ by using heme peroxidation as described in Tiwari et al. [31]. This method has been considered a reliable tool for comparing differences in general oxidase levels based on hemoprotein levels. Because heme constitutes the majority of cytochrome P₄₅₀ in non-blood-fed insects, quantification of heme activity has been used to compare the levels of cytochrome P₄₅₀ on the basis of general oxidase levels [33]. In brief, heme peroxidase activity was measured using 3,3',5,5'-tetramethylbenzidine (TMBZ) (Sigma Aldrich) as the substrate. Five replicates, each consisting of three insects, were performed for each treatment.

Gene expression analysis

Live adult D. citri from each treatment were subjected to RNA isolation and cDNA synthesis. RNA isolations were performed in
Silencing of Cytochrome P450 in Diaphorina citri

D. citri

A) Box blot representation was used as a non-targeted gene. Alpha-tubulin and the endogenous gene, Actin, were clearly detected in the microsomal proteins were initially main-Actin, D. citri [21] gene expression, Diaphorina citri adults was assessed after 24 h. dosage (general oxidase) activity and Cytochrome P450, as described in Tiwari et al. [21] (Table 1). Six biological replicates were performed for each treatment. The production of gene-specific products and absence of ‘primer dimers’ was verified by 1% agarose electrophoresis in TAE buffer with ethidium bromide staining.

The 2-ΔΔCT method was used to compare the relative expression of the consensus sequence among PCR products derived from the three dsRNA concentrations and control treatments [34]. This was done by first normalizing the expression level of dsRNA treated samples to Actin [21] gene expression, followed by normalization to the treatment giving the lowest gene expression. Alpha-tubulin was used as a non-targeted gene (control). Five biological replicates, each consisting of three insects and three technical replicates, were performed for each treatment.

Western blot assay

Subcellular protein fractions were extracted using the methods described by Wheeler et al. [35] from adults in each treatment. The protein concentration was determined by the Bradford method [36] using a protein assay kit (Bio-Rad Laboratories, Hercules, CA, USA) with ovalbumin as the standard. Since cytochrome P450 proteins were clearly detected in the microsomal protein [22], we used the microsomal fractions to perform the Western blot analysis, as described by Tiwari et al. [22].

Survival assay

The survival assay was carried out on D. citri treated with dsRNA-gfp, dsRNA- P450, or RNase-free water as a control. Insects were placed on an autoclaved clear plant tissue culture container (75×75×100 mm) lined with 0.5 mm filter paper saturated with 20% sucrose. Fifty insects were placed per container and five replicates were performed for each treatment. Live insects were counted daily.

Residual activity of dsRNA- P450

In order to assess the duration of the RNAi effect, 70 insects treated with RNase-free water or dsRNA-P450 (20 ng/insect) were placed into plant tissue culture containers with filter paper saturated with 20% sucrose. Samples consisting of three insects were taken daily and kept at −20°C. Cytochrome P450 (general oxidase) activity was measured in all samples as described above. Five replicates were performed for both treatments.

Pesticide application

To investigate the effect of treatment with dsRNA- P450 on insecticide resistance, D. citri adults were treated with the dsRNAs (20 ng/insect) as described above. D. citri were initially maintained on Petri dishes with untreated citrus leaf disks for 72 h and thereafter transferred to new Petri dishes that contained leaf discs treated with insecticide solution. Briefly, the leaf disks (60 mm diameter) were excised, dipped in the insecticide solution made in acetone for 30 s, and allowed to air dry in a fume hood for 1 h prior to placement into the Petri dishes as described by Tiwari et al. [26]. We used analytical-grade imidacloprid at the LD50 dosage (0.02 ng Al/µl acetone) previously determined by Tiwari et al. [26]. The mortality of D. citri adults was assessed after 24 h. dsRNA-gfp was used as a negative control for dsRNA- P450. Fives replicates (Petri dishes), with five insects each, were performed for each of the four D. citri populations tested. Each population was subjected to four different treatments: D. citri treated with RNase-free water on 1) RNase-free water- or 2) imidacloprid-treated disks, as well as D. citri treated with dsRNA- P450 on 3) RNase-free water- or 4) imidacloprid-treated leaf disks.

Figure 2. Cytochrome P450 (general oxidase) activity and protein expression in dsRNA-treated D. citri. A) Box blot representation was used as a non-targeted gene. Boxes indicate the interquartile range, including 50% of results, and the mid-horizontal lines represent the median; different letters above deviation error bars represent significant differences between treatments (P<0.05). B) Protein analysis of dsRNA-treated and control D. citri using Western blot. Western blot was performed using the microsomal proteins prepared from adults treated with three quantities of dsRNA and a control. dsRNA-gfp treatment was used as a control targeting an irrelevant gene. doi:10.1371/journal.pone.0110536.g002

three biological replicates using the SV total RNA isolation kit (Promega, Madison, WI, USA). The quantity and quality of RNA from each sample was measured on a NanoDrop 1000 Spectrophotometer using the absorbance at 260 nm and the A260/A280 ratio, respectively. Subsequently, cDNA was synthesized with the iScript cDNA synthesis kit (Bio-Rad, Hercules, CA, USA) for each replicate within each treatment. Quantitative real-time PCR (qPCR) was performed using iQ SYBR Green Supermix with an iCycler iQ real-time PCR detection system (Bio-Rad). Primers for five CYP4 genes, Alpha-tubulin and the endogenous gene, Actin, were used to measure the gene expression of cytochrome P450, as described in Tiwari et al. [21] (Table 1). Six biological replicates were performed for each treatment. The production of gene-specific products and absence of ‘primer dimers’ was verified by 1% agarose electrophoresis in TAE buffer with ethidium bromide staining.

The 2-ΔΔCT method was used to compare the relative expression of the consensus sequence among PCR products derived from the three dsRNA concentrations and control treatments [34]. This was done by first normalizing the expression level of dsRNA treated samples to Actin [21] gene expression, followed by normalization to the treatment giving the lowest gene expression. Each population was subjected to four different treatments: D. citri treated with RNase-free water on 1) RNase-free water- or 2) imidacloprid-treated disks, as well as D. citri treated with dsRNA- P450 on 3) RNase-free water- or 4) imidacloprid-treated leaf disks.
Statistical analysis
All analyses were performed using SPSS version 19.0. Survival was calculated during the interval from initial treatment to when all insects died. Overall survival (OS) curves were obtained using the Kaplan-Meier method and comparisons were made using log rank and Wilcoxon tests. Analysis of variance (ANOVA) was used:

i) Calculated D. citri lifespans between various treatments,
ii) The effect of dsRNA treatments on CYP4 activity and insecticide resistance, and
iii) The duration of the RNAi effect. Post hoc pairwise comparisons between treatments were performed with the Tukey honestly significant difference test. Statistical significance was established as \( P < 0.05 \).

Results
Treatment with dsRNA-P450 causes down regulation of five CYP4 genes
Relative expression levels for the five CYP4 genes were compared between dsRNA- \( P_{450} \), dsRNA-gfp-treated and control psyllids (Figure 1). Treatment with dsRNA- \( P_{450} \) caused reduced expression of the five CYP4 genes. The effect of dsRNA- \( P_{450} \) was positively correlated with the quantity applied per treatment. The expression level of \( \alpha \)-tubulin (non-target gene) remained constant among all treatments indicating the specificity of dsRNA- \( P_{450} \) to CYP4 genes. In contrast, there was no effect of the dsRNA-gfp control treatments targeting irrelevant psyllid genes on expression levels of CYP4 genes. The greatest reduction in expression level was found with CYP4G70, while the lowest effect was with CYP4C68. This observation may help in evaluating gene candidates for RNAi technology for D. citri.

Treatment with dsRNA-P450 reduces the protein expression and the enzymatic activity of CYP4
We investigated the effect of treating D. citri with dsRNA on general oxidase activity. The activities were similar for all doses of dsRNA-gfp treatment, while reduced when D. citri were treated with dsRNA-P450. The activity decreased as the concentration of applied dsRNA- \( P_{450} \) was increased. Additionally, Western blots performed using the microsomal fractions revealed the presence of a band corresponding to a 45 kDa protein that cross-reacted with

Figure 3. Effect of dsRNA- \( P_{450} \) on D. citri survival. A) Kaplan-Meier survival curve showing the effect of dsRNA- \( P_{450} \) treatment on lifespan of D. citri. B) Average life span of D. citri. Bars represent the standard deviations; different letters above error bars represent significant differences between treatments (\( P < 0.05 \)). dsRNA-gfp treatment was used as a control targeting an irrelevant gene.

Figure 4. \( P_{450} \) as measured by general oxidase activity. Asterisks indicate significant differences between dsRNA- \( P_{450} \) treated and non-treated D. citri, while ns indicates no significant differences (\( P < 0.05 \)).

doi:10.1371/journal.pone.0110536.g004
the primary antibody of cytochrome P450 protein. Twenty-five micrograms of microsomal proteins for each treatment were used to perform the Western blot which indicated the highest amount of cytochrome P450 proteins (detoxifying enzymes) in D. citri treated with 0 ng/ml of dsRNA, followed by D. citri treated with 10, 15, and 20 ng/insect of dsRNA (Figure 2). There was no signal detected in D. citri treated with 20 ng/insect of dsRNA. Expression levels of target CYP4 and oxidase activity, as a result of dsRNA treatment, directly correlated with the protein expression in adults treated with dsRNA.

Silencing of CYP4 reduced the lifespan of D. citri

Survival of D. citri was quantified following treatment with dsRNA-gfp, dsRNA-P450, and the control (water). The experiment was conducted under the conditions described earlier (Figure 3A). In this experiment, a 20 ng/insect concentration was used for both dsRNA-gfp and dsRNA-P450. A Kaplan-Meier survival plot indicated significant differences among all treatments (log rank = 154.63, P < 0.001). No significant differences in survival were found between the control and dsRNA-gfp-treated D. citri (log rank = 1.54, P = 0.64). The lifespan in dsRNA-P450-treated D. citri was significantly shorter than that observed for other treatments. Mean lifespans for the treatments are presented in Figure 3B. This suggests that reduced expression of CYP4 genes shortens the lifespan of D. citri.

Residual activity of dsRNA-P450 treatment

The residual activity of dsRNA-P450 was measured at 20 ng/insect concentration. We used general oxidase activity as an indicator for the residual of dsRNA-P450. We compared oxidase activity between the control and dsRNA-P450-treated D. citri daily after the treatment application. Oxidase activity was significantly reduced following application of dsRNA-P450 for up to 8 days (Figure 4).

Silencing of CYP4 increased insecticide susceptibility

In order to determine the effect of dsRNA-P450 on insecticide susceptibility of D. citri, we used imidacloprid at the LD50 dosage. Two susceptible and two resistant populations were used in this experiment (Figure 5). D. citri that were treated with RNase-free water and then exposed to leaf discs treated with imidacloprid exhibited differing susceptibilities, depending on the population tested (Figure 5). Specifically, the two populations from commercially managed citrus groves that had received imidacloprid

**Figure 5. Effect of dsRNA-P450 treatment on D. citri susceptibility to imidacloprid using the LD50 dosage.** A) Illustration of the protocol used to test the effect. B) Percent mortality of D. citri after exposure to imidacloprid for 24 h. Insects were maintained on non-treated leaf discs for 48 h after the dsRNA-P450 treatment prior to exposure to imidacloprid. LS: Laboratory susceptible population. OG: Susceptible population collected from an organic grove. PL: Resistant population collected from a commercially managed grove. LA: Resistant population collected from a commercially managed Lake County, Florida. Asterisks indicate significant differences, while ns indicates no significant differences (P < 0.05). doi:10.1371/journal.pone.0110536.g005
treatment over the previous several years (LA (Lake County) and PL (Polk County)) were less susceptible to imidacloprid at the LD_{50} dosage than D. citri collected from our Laboratory Susceptible culture (LS) and from the Organic Grove (OG) where imidacloprid had not been used previously (Figure 5). Mortality of D. citri exposed to imidacloprid after treatment with dsRNA-P_{50} was increased for each of the four populations as compared with the water control (Figure 5). Mortality of D. citri from the two resistant populations (LA, PL), at the LD_{50} dosage of imidacloprid, was significantly higher after treatment with dsRNA-P_{50} as compared with the water control (Figure 5). Given that dsRNA-P_{50} also increased mortality of D. citri from the two susceptible populations (LS and OG) further suggests that cytochrome P_{450} is implicated in imidacloprid resistance in D. citri.

Discussion

Most insect RNAi studies have relied on the delivery of specific dsRNA through either microinjections [4] or ingestion through feeding [10,13]. Each of these methods has advantages and disadvantages. The microinjection method requires intense training and is a notably time-consuming technique. In addition, optimization is required for volume selection, place of injection, and needle size for successful dsRNA injection into the insect body [7]. Delivery of dsRNA through ingestion also has limitations, such as reduced effectiveness for inducing RNAi [37], reduced efficacy of dsRNA due to the unfavorable gut environment [38], and difficulties in quantifying the amount of dsRNA ingested [39].

The current work highlights a novel method of dsRNA delivery through topical microapplication to the abdomen of adult D. citri. The ventral microapplication allows dsRNA uptake through the exoskeleton of insect. The uptake occurs via the intersegmental membranes. This investigation describes a relatively easy and efficient method for delivering and allowing the dsRNA to enter the insect’s body to induce RNAi. This method has also been described for D. citri nymphs with high efficiency of activity [32]. Also, a similar delivery method was reported to induce RNAi in Ostrinia nubilalis larvae [11].

A dosage as low as 50 ng/μl of dsRNA down-regulated the expression of the consensus sequence derived from five CYP4 genes from D. citri, as verified by qPCR and Western blot. The lifespan of D. citri following dsRNA treatment was statistically shorter than with untreated controls in the current investigation. In another example, mortality in O. nubilalis larvae ranged between approximately 40–50% following topical treatment with dsRNA [11]. The mortality, coupled with the lack of any other abnormality observed in the dsRNA-treated adult D. citri, suggests that the CYP4 specific dsRNA are highly target specific. Target specificity of dsRNA is also useful considering the potential for dsRNA exposure to non-target organisms under field conditions. Designing target specific dsRNA is not uncommon; species-specific dsRNA has been shown to work like an insecticide by killing specifically targeted insect pests [40]. The low concentrations needed for induction of RNAi and the highly specific nature of dsRNA suggest it might be a tool for managing insecticide resistance in D. citri. Our results indicate that dsRNA-P_{450} reduced oxidase activity, which presumably increased insecticide susceptibility in both resistant and susceptible populations of D. citri. In comparison, dsRNA-gfp (our negative control treatment) did not affect CYP4 gene expression or oxidase activity. These findings indicate specificity of RNAi for D. citri with the genes targeted in the present investigation.

An important challenge for the application of dsRNA for practical pest control is developing a delivery method for commercial field deployment. Another practical limitation of RNAi that needs to be addressed is that large quantities of dsRNA are expensive to produce. Currently, we are working on inserting the previously described dsRNA into citrus plants for direct ingestion by D. citri during feeding. Delivery of dsRNA through transgenic plants (Plant mediated RNAi) has been achieved in Helicoverpa armigera and Diabrotica vergifera vergifera [41,42]. The absence of interferon-regulated innate immunity pathways in insects allows the possibility of employing longer dsRNA for maximal RNAi [43]. Another potentially feasible way of delivering dsRNA would be to incorporate target-specific dsRNA into bacteria with an appropriate transfection reagent and then spraying the transformed bacteria onto citrus trees. However, future work is needed to evaluate the most efficient transfection reagents and bacterial formulations to prevent the breakdown of dsRNA under field conditions. Once the entire genome of D. citri is sequenced, this delivery method could be a convenient way to conduct high-throughput loss-of-function research for determining gene functions. In addition, the current results suggest that further work is needed to understand the mechanism of dsRNA entry into cells following topical application of dsRNA onto D. citri to induce RNAi.

Acknowledgments

We acknowledge Ian Jackson for D. citri collection and technical assistance.
