This study examines racial/ethnic, nativity, and sociodemographic disparities in the prevalence of pre-pregnancy obesity and overweight in the United States. Logistic regression was fitted to the 2012–2014 national birth cohort data to derive unadjusted and adjusted differentials in pre-pregnancy obesity (BMI ≥30), severe obesity (BMI ≥40), and overweight/obesity (BMI ≥25) prevalence among 10.4 million US women of childbearing age. Substantial racial/ethnic differences existed, with pre-pregnancy obesity rates ranging from 2.6% for Chinese and 3.3% for Vietnamese women to 34.9% for American Indians/Alaska Natives (AIANs) and 60.2% for Samoans. Pre-pregnancy overweight/obese prevalence ranged from 13.6% for Chinese women to 61.7% for AIANs and 86.3% for Samoans. Compared to non-Hispanic whites, women in all Asian subgroups had markedly lower risks of pre-pregnancy obesity, severe obesity, and overweight/obesity, whereas Samoans, Hawaiians, AIANs, blacks, Mexicans, Puerto Ricans, and Central/South Americans had significantly higher risks. Immigrant women in each racial/ethnic group had lower rates of pre-pregnancy obesity than the US-born. Sociodemographic risk factors accounted for 33–47% of racial/ethnic disparities and 12–16% of ethnic-immigrant disparities in pre-pregnancy obesity and overweight/obesity. Further research is needed to assess the effects of diet, physical inactivity, and social environments in explaining the reported ethnic and nativity differences in pre-pregnancy obesity.

1. Introduction

Obesity rates have increased dramatically in the United States during the past four decades, with the prevalence having more than doubled for all racial/ethnic, gender, immigrant, and socioeconomic groups [1–4]. Currently, 38% of US men and 40% of US women are classified as obese (body mass index (BMI) ≥30 kg/m²), and more than 70% of the US adult population are considered overweight or obese (BMI ≥25 kg/m²) [1, 2]. Rates of obesity and overweight/obesity for the US adult population are projected to reach 43% and 77%, respectively, by 2020 [4].

According to the national data, obesity prevalence among US women of childbearing age (18–49) increased nearly 4-fold, from 7.4% in 1976 to 27.5% in 2014; the overweight/obese prevalence rose from 22.8% in 1976 to 53.5% in 2014 [3, 5]. Nearly 4 million women give births each year in the US, and rates of pre-pregnancy obesity among mothers are high with a prevalence >20% [6, 7]. Pre-pregnancy obesity is associated with increased risk for
a number of adverse pregnancy and birth outcomes, including gestational diabetes, pre eclampsia, gestational hypertension, cesarean section, dysfunctional and prolonged labor, induced labor, miscarriage, stillbirth, fetal macrosomia, preterm birth, select birth defects, and infant mortality [7–14]. Women with pre-pregnancy obesity are also at greater lifetime risks for developing chronic hypertension and type 2 diabetes than those of normal weight [11]. Children born to women with pre-pregnancy obesity are at increased risk of obesity during childhood and adult life [9, 11, 13].

Data from the Pregnancy Risk Assessment and Monitoring System (PRAMS) indicate a significant rise in the prevalence of pregnancy-related obesity in 20 US states, increasing from 17.6% in 2003 to 20.5% in 2009 [7]. Studies using PRAMS and birth certificate data show highest rates of pre-pregnancy obesity among non-Hispanic black women and American Indians/Alaska Native (AIAN) women, followed by Hispanics, non-Hispanic whites, and Asian/Pacific Islanders (APIs) [7, 13, 15, 16]. Socioeconomic differences in pre-pregnancy obesity have also been reported, with women at lower education and income levels having markedly higher prevalence [13, 16]. Despite the many adverse health effects of obesity in the preconception period, detailed racial/ethnic and sociodemographic risk factors associated with increased risk of pre-pregnancy obesity are not well documented in the US. While maternal pre-pregnancy obesity prevalence for broad racial/ethnic groups has previously been reported [7, 13, 15–17], disparities in pre-pregnancy obesity and overweight among specific API, Hispanic, and immigrant subgroups are not analyzed. Moreover, although characteristics such as maternal age, parity, marital status, education, and place of residence have been mentioned as possible risk factors for maternal obesity, few studies have examined racial/ethnic and immigrant disparities adjusted for these factors [7, 12, 13]. A better understanding of pre-pregnancy obesity risks and their determinants among major racial/ethnic and immigrant groups is vital to improving preconception health and health outcomes among mothers and children. Targeted and culturally relevant interventions for obesity prevention and control can reduce overall health disparities, improve intergenerational weight trends, and promote health equity for the nation [3, 4, 8].

The primary aim of this study is to examine the extent of racial/ethnic and immigrant disparities in the prevalence of pre-pregnancy obesity and overweight among US women and to identify relevant sociodemographic risk factors, using the latest national birth cohort data. The study also explores a wider range of social inequalities by examining whether racial/ethnic disparities in pre-pregnancy obesity and overweight vary according to nativity/immigrant status and maternal education. Since immigration is a major characteristic of the Asian and Hispanic populations and nearly a quarter of all US births occur among foreign-born mothers [6], our analysis is also stratified by nativity status to highlight immigrant differences in obesity rates within each racial/ethnic group.

2. Methods

Maternal pre-pregnancy BMI data in this study are derived from the birth certificates filed in the 50 states, New York City, and the District of Columbia (DC) [6, 18]. These data have been included in the annual natality files by the National Center for Health Statistics, Centers for Disease Control and Prevention (CDC), for selected states since 2003. The number of states reporting pre-pregnancy BMI data increased from 40 in 2012 to 42 in 2013 and 48 in 2014 [6, 18]. The annual natality file includes birth certificate data for about 4 million births that occur in the United States each year [6, 18]. The US Standard Certificate of Live Birth is the basis for the national birth data [6].

In addition to pre-pregnancy BMI and detailed race/ethnicity, the birth certificate data include maternal and paternal age, nativity/immigrant status, marital status, education, place of residence, parity/birth order, birth interval, birth weight, gestational age, congenital anomalies of the newborn, tobacco and alcohol use during pregnancy, prenatal care utilization, gestational weight gain, method of delivery (vaginal or cesarean), attendant at birth, pregnancy history, and a variety of medical risk factors and complications such as pre-pregnancy and gestational diabetes, chronic and pregnancy-induced hypertension, eclampsia, uterine bleeding, placenta previa, prolonged labor, and induction of labor. Detailed descriptions of the birth certificate data and national natality files are available elsewhere [1, 6, 18, 19].

We used the 2012–2014 national birth cohort data [6, 18]. During 2012–2014, 11,873,098 births occurred among US mothers. Approximately 12.1% of the births did not include pre-pregnancy maternal BMI data, which included several states that did not report BMI data during the three years [18]. The sample for the analysis included 10,431,092 live births. Of these, 2,529,920 births occurred among mothers with pre-pregnancy obesity, 5,191,191 births among mothers with pre-pregnancy overweight/obesity, and 459,283 births among mothers with severe obesity. Aggregating data for three years ensured sufficient sample sizes for analyzing obesity patterns among groups stratified by race/ethnicity, immigrant status, and maternal education. Consistent with the WHO and CDC guidelines, pre-pregnancy overweight/obesity was defined as a BMI ≥25 kg/m², obesity as a BMI ≥30 kg/m², and severe or grade 3 obesity as a BMI ≥40 kg/m² [1–4, 20]. Note that the overweight/obesity category includes obese women.

Race/ethnicity was classified into 17 major categories: Non-Hispanic whites, Non-Hispanic blacks, AIANs, Chinese, Asian Indians, Filipinos, Japanese, Koreans, Vietnamese, Hawaiians, Samoans, and other Asian/Pacific Islanders, Mexicans, Puerto Ricans, Cubans, Central and South Americans, and other Hispanics. Immigrant status was defined on the basis of mothers’ place of birth [6, 18, 19]. US-born were those born in one of the 50 states or Washington, DC. Immigrants or foreign-born refer to those born outside these territories [6, 18, 19]. The joint variable of ethnic-immigrant status included 31 categories, with each racial/ethnic group divided into the US-born and foreign-born.
RMSD is an estimate of relative disparity and is given by the coefficient of variation (CV) of the RMSD provides an estimate other than the sample mean. \( \text{RMSD} = \sqrt{\frac{\sum (O_i - O_d)^2}{I}} \),

where \( O_i \) is the obesity or overweight/obesity prevalence for the \( i \)th group \((i = 1, 2, \ldots, I)\), \( O_d \) is the corresponding statistic for the “standard” group (total US population) or group with the lowest prevalence \( i.e., \) Chinese women, and \( I \) is the number of racial/ethnic or ethnic-immigrant groups \( I \) being compared.

While RMSD is a measure of absolute health disparity, the coefficient of variation (CV) of the RMSD provides an estimate of relative disparity and is given by

\[ \text{CV(RMSD)} = \left( \frac{\text{RMSD}}{O_{d}} \right) \times 100, \quad O_{d} > 0. \]

In both the obesity and overweight/obesity models, we examined interactions of race/ethnicity with nativity and maternal education by estimating logistic models that included the joint variables of ethnicity-immigrant status and race/ethnicity-education. Fitted logistic models were used to derive adjusted obesity and overweight prevalence at mean values of the covariates [4, 21].

3. Results

3.1. Racial/Ethnic Disparities in Pre-Pregnancy Obesity and Overweight. During 2012–2014, the overall prevalence of pre-pregnancy obesity and overweight/obesity among US mothers was 24.3% and 49.8%, respectively. Of all racial/ethnic groups, Samoan women had the highest prevalence of pre-pregnancy obesity (60.2%), followed by AIANs (34.9%), blacks (33.9%), Hawaiians (32.4%), Puerto Ricans (28.6%), and Mexicans (28.0%) (Table 1). Chinese women had the lowest pre-pregnancy obesity prevalence at 2.6%. Indeed, all Asian subgroups, including Chinese, Japanese, Vietnamese, Koreans, Asian Indians, and Filipinos, had markedly lower pre-pregnancy obesity prevalence than non-Hispanic whites (22.3%). Mexicans and Puerto Ricans had significantly higher prevalence of pre-pregnancy obesity than non-Hispanic white women.

Pre-pregnancy overweight/obesity prevalence ranged from a low of 13.6% for Chinese women to 61.7% for AIANs and 86.3% for Samoans (Table 2). Overweight/obesity prevalence exceeded 55% for Puerto Ricans, Mexicans, Hawaiians, and blacks but was lower than 20% for Vietnamese, Japanese, and Korean mothers. The overall prevalence of severe pre-pregnancy obesity among US mothers was 4.4% (Figure 1). Chinese women had the lowest prevalence of severe obesity (0.1%), with all major Asian subgroups reporting a prevalence of <1%. Samoans had the highest prevalence of severe obesity (16.0%), followed by blacks (7.7%), AIANs (6.6%), Hawaiians (6.5%), and Puerto Ricans (5.4%).

Racial/ethnic groups varied greatly in their sociodemographic characteristics that are associated with pre-pregnancy obesity (Table 3). For example, while <12% of births occurred among AIAN, Puerto Rican, and black mothers aged \( \geq 35 \) years, this percentage was 35% among Chinese and 49% among Japanese mothers. More than 19% of Hawaiian, Samoan, and AIAN mothers reported previously having 4 or more births, compared to <3% of Chinese and Asian Indian mothers. Educational attainment was highest among Asian Indian and Korean women and lowest among Mexican and Samoan women. The percentage of mothers with a college degree ranged from 75.3% for Koreans and 77.0% for Asian Indians to 7.5% for Samoans, 8.4% for Mexicans, and 9.3% for AIANs. More than 87% of Chinese and Asian Indian mothers were foreign-born, compared with 6.2% of non-Hispanic whites and 14.2% of blacks. The proportion of births outside marriage was much higher among blacks, AIANs, and Hispanics compared to white and Asian women. The percentage of unmarried mothers ranged from 3.5% for Asian Indians and 7.0% for Japanese to 63.4% for Puerto Ricans, 66.3% for AIANs, and 71.4% for blacks. More than 55% of Hawaiian, Japanese, Filipino, and Samoan mothers resided in the Western region, compared to 7.7% of Puerto Ricans and 8.7% of blacks.

After controlling for sociodemographic factors, Central/South Americans, Puerto Ricans, Mexicans, Hawaiians, AIANs, and non-Hispanic blacks had 26–82% higher odds of pre-pregnancy obesity and 48–86% higher odds of overweight/obesity compared to non-Hispanic white women (Tables 1 and 2). Samoans had 6.1 times higher adjusted odds of pre-pregnancy obesity and 8.0 times higher adjusted odds of overweight/obesity compared to non-Hispanic whites. Blacks and Samoans, respectively, had 2.0 and 5.7 times higher adjusted odds of severe obesity than non-Hispanic whites (data not shown).
| Covariate                        | Number of births | Prevalence percent | Prevalence ratio | Model 1  | Model 2  | Covariate-adjusted |
|----------------------------------|------------------|--------------------|------------------|----------|----------|-------------------|
|                                  |                  |                    |                  | OR       | 95% CI    | Prevalence        |
| Past age (years)                 |                  |                    |                  | Prevalence| SE       |                   |

Table 1: Observed prevalence and logistic regressions showing unadjusted and covariate-adjusted differentials in pre-pregnancy obesity (BMI ≥30) among reproductive-age women in major racial/ethnic groups and by selected sociodemographic characteristics, United States, 2012–2014 (N = 10,431,092)
Non-Hispanic white women, on the other hand, had 5.8 higher adjusted odds of pre-pregnancy obesity, 3.7 times higher adjusted odds of overweight/obesity, and 14.3 times higher adjusted odds of severe obesity compared to Chinese women. Indeed, compared to non-Hispanic whites, women in all Asian subgroups had 21–93% lower odds of pre-pregnancy obesity, severe obesity, and overweight/obesity.

Tables 1 and 2 show variation in prevalence and odds of pre-pregnancy obesity and overweight/obesity according to other sociodemographic characteristics. Increasing maternal age and parity, lower education, US-born status, non-metropolitan residence, and residence in the Midwest and Southern regions were independently associated with pre-pregnancy obesity and overweight. Mothers aged 40–44 years had 3.5 times higher adjusted odds of pre-pregnancy obesity and 3.2 times higher adjusted odds of overweight/obesity than those aged <20 years. US-born mothers had 86% higher adjusted odds of pre-pregnancy obesity and 35% higher odds of overweight/obesity than immigrant mothers. Mothers in the Midwest and Southeast regions had 22–34% higher adjusted odds of pre-pregnancy obesity and overweight/obesity than those in the Mountain region. Mothers with lower education levels had two times higher adjusted odds of pre-pregnancy obesity than those with a college degree. Risk of pre-pregnancy obesity and overweight/obesity increased consistently with increasing maternal parity. Based on disparity indices, sociodemographic factors accounted for 33%, 47%, and 61% of the racial/ethnic disparities in pre-pregnancy overweight/obesity, obesity, and severe obesity, respectively.

3.2. Ethnic-Immigrant Disparities in Pre-Pregnancy Obesity and Overweight/Obesity. Pre-pregnancy obesity ranged from 1.9% for Chinese immigrants to 35.7% for US-born blacks and 60.2% for Samoans (Table 4). US-born Chinese women had 3.7 times higher risk of obesity than Chinese immigrants, while US-born black women had 51% higher risk of obesity than immigrant black women. Overweight/obesity prevalence ranged from 10.5% for Japanese immigrants and 12.1% for Chinese immigrants to 61.7% for US-born blacks and AIANs and 86.3% for Samoans (Table 5). US-born Chinese and Japanese women had 2 and 3 times higher risks of overweight/obesity compared to their foreign-born counterparts, respectively. Prevalence of severe pre-pregnancy obesity varied from a low of <0.50% for Chinese, Japanese, Vietnamese, Korean, Asian Indian, and Filipino immigrants to a high of 8.6% for US-born blacks and 16.0% for Samoans (Figure 2).

Ethnic-immigrant disparities in obesity risks were greater than disparities shown by race/ethnicity alone. Compared with US-born whites, the adjusted odds of obesity were 49% lower for white immigrants, 83% higher for US-born blacks, 6% lower for black immigrants, 61% higher for US-born Mexicans, and 8% lower for Mexican immigrants (Table 4). Compared with US-born whites, all US-born and foreign-born Asian subgroups had 19–93% lower adjusted odds of obesity. Compared with US-born whites, the adjusted odds of overweight/obesity were 36% lower for white immigrants, 83% lower for Chinese immigrants, and 57% lower for US-born Chinese (Table 5). All Asian nativity groups had significantly lower adjusted risks of overweight/obesity than US-born whites. Compared with US-born whites, the adjusted odds of severe obesity were 4.2 times higher for Samoans, 2.1 times higher for US-born blacks, and 1.2 times higher for AIANs. However, compared with US-born whites, the adjusted odds of severe obesity was 68% lower for white immigrants and 52% lower for black immigrants. All Asian nativity groups had considerably lower adjusted risks of severe obesity than US-born whites (data not shown). Sociodemographic factors accounted for 12%, 16%, and 21% of ethnic-immigrant disparities in pre-pregnancy overweight/obesity, obesity, and severe obesity, respectively.

3.3. Ethnic-Specific Educational Gradients in Pre-Pregnancy Obesity and Overweight.

Marked educational inequalities in pre-pregnancy obesity and overweight/obesity were generally found for all broad racial/ethnic groups, with mothers with less than a college education having significantly higher obesity and overweight/obesity prevalence than their counterparts with a college degree (Table 6). Obesity prevalence ranged from 6.2% for API women with a college degree to over 37% for black and AIAN women with 13–15 years of education. Overweight/obesity prevalence ranged from 25.3% for API women with a college degree to over 64% for black and AIAN women with 13–15 years of education. Compared with API women with a college degree, the adjusted odds of obesity were almost 4 times higher for white women with less than a college degree and 5–7 times higher for Hispanic, AIAN, and black women with less than a college degree. The patterns in overweight/obesity risks were similar. Within each educational stratum, significant racial/ethnic disparities in obesity and overweight risks existed.
Table 2: Observed prevalence and logistic regressions showing unadjusted and covariate-adjusted differentials in pre-pregnancy overweight or obesity (BMI $\geq 25$) among reproductive-age women in major racial/ethnic groups and by selected sociodemographic characteristics, United States, 2012–2014 ($N = 10,431,092$).

4. Discussion

To our knowledge, this is the largest population-based study of pre-pregnancy obesity in the US. We have shown marked disparities in pre-pregnancy obesity among a large number of racial/ethnic and immigrant groups in the US, maternal obesity risks for many of which were not previously examined. For several racial/ethnic groups, pre-pregnancy obesity

Source: data derived from the 2012–2014 US National Natality data files. AN = Alaska Native.
Substantial geographic variation in adult obesity prevalence has previously been reported, and our findings of higher prevalence of pre-pregnancy obesity among women in the US [3, 4, 19]. Previous studies have shown Hispanics to be at an increased risk of pre-pregnancy obesity and adult obesity [1–3, 7, 13, 16]. Compatible with adult obesity patterns, our analysis showed particularly high risks of pre-pregnancy obesity among Mexicans and Puerto Ricans compared to non-Hispanic whites and Asian subgroups [3, 18].

Substantial geographic variation in adult obesity prevalence has previously been reported, and our findings of higher prevalence of pre-pregnancy obesity in the Midwest and Southern regions are consistent with the previously reported regional patterns [1, 3, 22]. Increased risk of pre-pregnancy obesity associated with lower maternal education is consistent with studies showing association between low socioeconomic status and higher obesity levels in women [1, 3, 13, 16, 22]. Diet, physical activity, genetic, and social environmental factors could account for ethnic, immigrant,

### Table 4: Observed prevalence and adjusted odds and prevalence of pre-pregnancy obesity (BMI ≥30) among women in 31 ethnic-immigrant groups, United States, 2012–2014 (N = 10,431,092).

OR = odds ratio; CI = confidence interval; API = Asian/Pacific Islander. *Statistically significant at p < 0.05. 1Unadjusted for the effects of other covariates. 2Adjusted for race/ethnicity, maternal age, parity, marital status, nativity, maternal education, and place and region of residence. Source: data derived from the 2012–2014 US National Natality data files.

levels were found to be very high, such as Hawaiians, blacks, AIANs, and Samoans who have a prevalence of 32%, 34%, 35%, and 60%, respectively. Indeed, more than 86% of Samoan women were classified as overweight or obese entering into pregnancy, with the prevalence exceeding 60% for Hawaiians, AIANs, and US-born black women. The results of our national study indicate substantial racial/ethnic and nativity disparities in the risk of maternal pre-pregnancy obesity and overweight, which were only partially explained by socioeconomic and demographic differences.

The increased risk of pre-pregnancy obesity observed here for several ethnic-minority and socially disadvantaged groups such as AIANs, blacks, Mexicans, Puerto Ricans, Hawaiians, and Samoans is consistent with prior studies reporting high levels of obesity and overweight among adult women in these subgroups [3, 4, 7, 13, 16, 19]. Similarly, low levels of obesity and overweight among specific Asian subgroups such as Chinese, Japanese, Vietnamese, Koreans, Asian Indians, and Filipinos are consistent with those reported in previous studies on adult obesity in the US [3, 4, 19]. Previous studies have shown Hispanics to be at an increased risk of pre-pregnancy obesity and adult obesity [1–3, 7, 13, 16]. Compatible with adult obesity patterns, our analysis showed particularly high risks of pre-pregnancy obesity among Mexicans and Puerto Ricans compared to non-Hispanic whites and Asian subgroups [3, 18].

Substantial geographic variation in adult obesity prevalence has previously been reported, and our findings of higher prevalence of pre-pregnancy obesity in the Midwest and Southern regions are consistent with the previously reported regional patterns [1, 3, 22]. Increased risk of pre-pregnancy obesity associated with lower maternal education is consistent with studies showing association between low socioeconomic status and higher obesity levels in women [1, 3, 13, 16, 22]. Diet, physical activity, genetic, and social environmental factors could account for ethnic, immigrant,
and socioeconomic disparities in pre-pregnancy obesity [3, 4, 7, 8, 11, 23].

Although immigrants account for 13% of the total US population, immigrant women make up approximately 20% of the reproductive-age population [24]. Given the profound inequalities in obesity by nativity/immigrant status shown here and in previous studies and the fact that immigrants represent a larger percentage of the population aged 15–49 than all ages, the magnitude of health disparities is likely to be greater for women in reproductive age than for the general population, all else being equal [3, 4, 19]. Although immigrant women in each racial/ethnic group had lower rates of pre-pregnancy obesity and overweight than the US-born, their reduced obesity risks and other health advantages are likely to diminish with increasing acculturation levels or duration of residence in the US [3, 4, 19, 25]. Although genetic factors might partly explain racial/ethnic disparities in pre-pregnancy obesity, findings from previous studies on migrant health as well as lower obesity risks among immigrants of similar ethnicities seen here might indicate the significance of social environments, acculturation, and lifestyle factors [3, 4, 19, 25]. Ethnic-minority and socially disadvantaged groups in the US differ greatly from the majority, affluent groups in their social, physical, and living environments. They have limited access to neighborhood amenities such as sidewalks, parks/playgrounds, green spaces, public transportation, and healthy, affordable foods that promote physical activity, healthy lifestyle, and healthy living [3, 4, 25, 26].

Our study has some limitations. Because of lack of data, important risk factors for obesity such as diet, physical activity, and the social and built environments could not be taken into account. Moreover, prevalence estimates of pre-pregnancy obesity and overweight were for women who had a live birth during 2012–2014 and excluded women who became pregnant but experienced fetal loss, miscarriages, or abortions [6, 18]. Since pre-pregnancy obesity in women is associated with these adverse perinatal outcomes, the reported pre-pregnancy obesity prevalence is likely to be underestimated [7]. Additionally, since pre-pregnancy

### Table 5: Observed prevalence and adjusted odds and prevalence of pre-pregnancy overweight or obesity (BMI ≥ 25) among women in 31 ethnic-immigrant groups, United States, 2012–2014 (N = 10,431,092)

weight on the birth certificate is self-reported by the mothers, pre-pregnancy obesity and overweight prevalence is likely to be underestimated [7]. The advantages of our study are its large sample size, national representativeness, and the ability to estimate pre-pregnancy obesity prevalence for a large number of racial/ethnic and immigrant groups, allowing for a more nuanced understanding of ethnic and socioeconomic disparities.

4.1. Implications for Practice and Policy. Factors such as inequalities in the social and built environments, physical activity levels, and dietary behavior are likely determinants of the racial/ethnic and nativity disparities in maternal pre-pregnancy obesity shown here [3, 4, 7, 11, 23, 26, 27]. Regular obstetric/gynecologic encounters offer an opportunity for behavioral counseling and lifestyle interventions to improve dietary intake and physical activity from pre-conception through pregnancy and well into the postpartum period [7, 11, 13, 28, 29]. Clinical guidelines are necessary to make improvements to the preconception, pregnancy, and postpartum visits [30, 31]. Interventions during these frequent medical encounters may be an effective strategy to counteract the rising rates of maternal obesity in the US [11, 29, 30]. Obesity is a leading health-risk factor for the nation and is associated with excess morbidity and mortality [2, 3, 32]. Due to high prevalence, a rapidly increasing trend, and large social-group disparities, obesity is a major public health concern due to its linkage to a myriad of chronic health conditions and the considerable toll it takes on healthcare costs [2, 3, 32, 33]. Marked social inequalities in pre-pregnancy obesity among US women contribute to persistent disparities in maternal and child health and overall health.

The recent release of the *US Dietary Guidelines for Americans 2015–2020* provides evidence-based recommendations for health and nutrition. Counterpart guidelines for women of reproductive age are necessary to provide specific...
recommendations for this subpopulation [34]. The nutritional needs for women vary during pregnancy to provide adequate nutrients to the fetus and postpartum particularly among lactating women. In addition, obese women tend to give rise to infants who are of large-for-gestational age [35]. Healthy eating patterns and regular physical activity can help women, pre-pregnancy, during pregnancy, and postpartum, to optimize fetal growth and development, thus changing the intergenerational trajectory of obesity.

5. Conclusions

This large population-based study of 10.4 million US women has shown considerable heterogeneity in pre-pregnancy obesity and overweight risks across various racial/ethnic and immigrant groups. Some of the ethnic-minority groups such as Samoans, Hawaiians, Puerto Ricans, Mexicans, AIANs, and non-Hispanic blacks have relatively high levels of maternal obesity, ranging from 32% to 60%. High rates of pre-pregnancy obesity correspond closely with the increased risks of various adverse maternal and perinatal outcomes among these groups such as gestational hypertension and diabetes, preeclampsia, pregnancy complications, preterm birth, and infant mortality. Immigrants have substantially lower rates of pre-pregnancy obesity and overweight than their US-born counterparts regardless of race/ethnicity. These findings highlight the significance of stratifying obesity analyses by immigrant status and suggest ethnic group-specific and culturally appropriate interventions to prevent obesity in women of reproductive age and to improve health outcomes [3, 4, 19, 23]. Further research is needed to assess the role of sociobehavioral and environmental factors responsible for ethnic, immigrant, and sociodemographic disparities in maternal pre-pregnancy obesity.
