Magnetic second-order topological insulators and semimetals

Motohiko Ezawa

Department of Applied Physics, University of Tokyo, Hongo 7-3-1, 113-8656, Japan

We propose magnetic second-order topological insulators (SOTIs). First, we study a three-dimensional model. It is pointed out that the previously proposed topological hinge insulator has actually surface states along the (001) direction in addition to hinge states. We gap out these surface states by introducing magnetization, obtaining a SOTI only with hinge states. The bulk topological number is the $Z_2$ index protected by the combined symmetry of the four-fold rotation and the inversion symmetry. We next study two dimensional magnetic SOTIs, where the corner states are robust also in the presence of the magnetization. Finally, we construct a magnetic second-order topological semimetals by layering the two-dimensional magnetic SOTIs, where hinge-arc states are robust also in the presence of the magnetization.

**Introduction:** Topological insulators (TIs) have opened a new world in condensed matter physics. The first example is the quantum Hall insulator, where the topological number is the Chern number. It is not necessary to require any symmetries for the quantization of the Chern number. The current movement of the topological insulator has started with the time-reversal invariant topological insulator, where the topological number is the $Z_2$ index protected by the time reversal symmetry (TRS). Then, it is generalized to the topological crystalline insulator, where the mirror Chern number is the topological number. Here the mirror symmetry protects the topological phase. Recent interest is renewed in topological insulators protected by more general crystalline symmetries including the rotational symmetry.

Higher-order topological insulators are extension of the TIs, to which the conventional bulk-boundary correspondence is generalized. Here we focus on three dimensional (3D) crystals. Then, the second-order TI (SOTI) has 1D topological boundary states (hinge states) but has no 2D topological boundary states (surface states), while the third-order TI has 0D topological boundary states (corner states) but has neither surface states nor hinge states. Recently, bismuth was predicted and shown to be an SOTI theoretically and experimentally by employing topological quantum chemistry. As a closely related concept to the SOTI, there are topological hinge insulators just mentioned above. As we see in Fig.1(b), there appear only two surface states perpendicular to the $z$ axis in addition to four hinge states: See Fig.1(b).

In this paper, introducing magnetization along the $z$ axis, first we propose a 3D magnetic SOTI by gapping out all the surface states in the topological hinge insulator just mentioned above. As we see in Fig.1(c) and (d), there appear only hinge states without surface states in the presence of the magnetization. The bulk topological number is shown to be the $Z_2$ index protected by the rotoinversion symmetry $\bar{C}_4 = C_4I$, which is the combined symmetry of the four-fold rotation $C_4$ and the inversion $I$. Second, we construct a 2D magnetic SOTI, where topological corner states appear. Finally, we construct a magnetic second-order topological semimetals based on the stacking of the 2D magnetic SOTI, where hinge-arc states emerge connecting the gap closing points.

**3D magnetic SOTI:** The typical model for the 3D TI is given by

$$H_0 = \left( m + t \sum_i \cos k_i \right) \tau_z \sigma_0 + \lambda \sum_i \sin k_i \tau_x \sigma_i$$  \hspace{1cm} (1)$$

on the cubic lattice, where $i$ runs over $x, y, z$. It describes topological Kondo insulators SmB$_6$. The $\sigma_i$ represent the Pauli matrices corresponding to the spin degrees of freedom and $\sigma_0$ is the two by two identity matrix, while $\tau_i$ are the Pauli matrices.
We show the phase diagram in Fig.2. In the absence of the Zeeman term\textsuperscript{20}, the system is topological for $1 < |m/t| < 3$ and trivial for $|m/t| < 1$ or $|m/t| > 3$. See Fig.2. Insulators emerge in the region including the phases with $B = 0$.

Later we identify the bulk topological number $\nu$ and find that it changes its value at these phase boundaries: See (11). The phase diagram consists of topological and trivial insulator phases and Weyl semimetal phases.

**Symmetries:** In order to identify the bulk topological invariant, it is necessary to study the symmetry of the Hamiltonian $H_0$. We note that $TH_0(k)T^{-1} = H_0(-k)$ and $IH_0(k)I^{-1} = H_0(-k)$, where $T = \tau_2 \sigma_0$ generates the TRS with the complex conjugation $K$, while $I = \tau_2 \sigma_0$ the inversion symmetry. In addition, there is a four-fold rotational symmetry $C_4$,

$$C_4 H_0(k_x, k_y, k_z) C_4^{-1} = H_0(-k_y, k_x, k_z), \quad (8)$$

is the generator of the $\pi/4$ rotation. The $H_\Delta$ breaks both of the TRS and the inversion symmetry but preserves\textsuperscript{20} the combined symmetry $C_4 T$ and the rotoinversion symmetry $C_4 \bar{C}_4$. Our concern is the effect of the Zeeman term. The Zeeman term $H_Z$ breaks $C_4 T$ but preserves $\bar{C}_4$.

**$Z_2$ index protected by $C_4$:** We can define\textsuperscript{12,20} the $Z$ index $\kappa_4$ protected by the rotoinversion symmetry $\bar{C}_4$,

$$\kappa_4 = \frac{1}{2\sqrt{2}} \sum_K \sum_\alpha e^{i\frac{\alpha\pi}{4}} n_K^{\alpha}, \quad (10)$$

where $K$ runs over the high symmetry points $\Gamma, S, Z, R$; $n_K^{\alpha}$ is the number of the occupied bands with the eigenvalue $e^{i\frac{\alpha\pi}{4}}$ of the symmetry operator $\bar{C}_4$, $\bar{C}_4 |\psi\rangle = e^{i\frac{\alpha\pi}{4}} |\psi\rangle$. Because of the relation $(\bar{C}_4)^4 = -1$, $\alpha$ is quantized to be $\alpha = 1, 3, 5, 7$. We explicitly evaluate $\kappa_4$ using the formula (10), which is shown in Fig.2. It follows that the topological phases at $B = 0$ are extended to the regions with $B \neq 0$, as shown in Fig.2. When the TRS is present, there is a relation\textsuperscript{12} that $\text{mod}_2 \kappa_4 = \nu_0$, where $\nu_0$ is the $Z_2$ index for the time-reversal-invariant topological insulators. Furthermore, by calculating the band structure of a square prism, we can check that no hinge states emerge for $B \neq 0$ in the phase indexed by $\kappa_4 = 0, \pm 2$ in the phase diagram (Fig.2). It implies that the bulk topological

![Fig. 2: 3D SOTI. Topological phase diagram in the $(m/t, B/t)$ plane. Numbers in red represent the $Z$ index $\kappa_4$, which gives the topological number $\nu$ by the formula $\nu = \text{mod}_2 \kappa_4$. The symbol $W$ stands for Weyl semimetal phases. The SOTI phases are marked in yellow.](image)

![Fig. 3: 3D SOTI. Surface band structure of a thin film. Surface states of the topological hinge insulator: (a) along the [001] and [010] direction; (b) those along the [001] direction, where the gap closes at the $M$ point in the surface Brillouin zone; (c) Surface states of the magnetic SOTI along the [001] direction with $B = t/2$. The surface states are gapped in the presence of magnetization.](image)
index is given by
\[ \nu = \text{mod}_{2 \pi} \kappa_4, \quad (11) \]
which is a generalization of \( \nu_0 \) in the absence of the TRS.

Surface states: We study the surface states in the topological phase. It is shown that the surface states along the [100] and [010] directions are gapped due to the term \( H_\Delta \) as in Fig.3(a). However, we find the gapless surface states along the [001] direction as in Fig.3(b). This is because that the \( C_4T \) and \( C_4 \) symmetries are preserved along the [001] direction but broken along the [100] and [010] directions. Because of the emergence of the topological surface states, the topological hinge insulator is not a SOTI. Nevertheless, this gapless surface states can be gapped out by introducing the Zeeman term as in Fig.3(c). On the other hand, the [100] and [010] surface states remain to be gapped in the presence of the Zeeman term.

Hinge states: We calculate the band structure of a square prism in the topological insulator phase to examine the hinge states. The hinge states remain as they are even in the presence of the magnetization, as shown in Fig.4. These hinge states are protected by the \( Z_2 \) index associated with the \( C_4 \) symmetry.

2D magnetic SOTI: Next, we study a magnetic SOTI model in two dimensions. The Hamiltonian is given by setting \( t = x, y \) in the Hamiltonian of the SOTI in three dimensions. The symmetry analysis is almost the same as in the 3D case just by neglecting the \( z \) coordinate. We discuss the properties of a 2D magnetic SOTI in the following order.

Topological phase diagram: The Brillouin zone is a square with four corners, \( \Gamma = (0, 0), X = (\pi, 0), Y = (0, \pi) \) and \( M = (\pi, \pi) \). The massive Dirac cone exists at the \( M \) point for \( |m - 2t| < |m + 2t| \) and at the \( \Gamma \) point for \( |m - 2t| > |m + 2t| \). There are two high-symmetry points, \( \Gamma \) and \( M \). At these points the TRS and the \( C_4 \) symmetry are respected. The energy spectrum reads \( E = \pm \sqrt{2t + \eta m} \) with the two-fold degeneracy at the \( \Gamma \) point with \( \eta = 1 \) and at the \( M \) point with \( \eta = -1 \). In the presence of the Zeeman term, the energies at these points are analytically given by
\[ E(0,0) = 2t + m \pm B, \quad -2t - m \pm B, \quad (12) \]
\[ E(\pi,\pi) = 2t - m \pm B, \quad -2t + m \pm B. \quad (13) \]
The topological phase diagram, given in Fig.5(a), consists of a SOTI phase, Chern TI (CI) phases and trivial insulator

FIG. 4: 3D SOTI. Band structure of the hinge states (a) without the Zeeman term and (b) with the Zeeman term \( B = t/2 \). The hinge states survive even in the presence of the Zeeman term. The horizontal axis is the momentum \( k_z \). We have set \( m/t = 2, \lambda = t \) and \( \Delta = t/4 \).

![Image](image_url)

FIG. 5: 2D SOTI. (a) Topological phase diagram in the \( (m/t, B/t) \) plane, which contains three distinctive phases: the trivial phase, the SOTI phase and the Chern TI (CI) phase. Band structures of (b) a nanoribbon in the absence of the \( H_\Delta \) term and (c) the one in the presence of the \( H_\Delta \) term, where we have chosen \( \Delta = t/4 \). Red curves represent edge modes in (b). We have set \( m = \lambda = t \).

![Image](image_url)

FIG. 6: 2D SOTI. Eigenvalues of the square (a) without magnetization and (b) with magnetization (\( B = t/2 \)). (a2) and (b2) Enlarged figures of the green areas in (a1) and (b1). Four zero-energy states indicated in red are observed. (a3) and (b3) Corresponding local charge distributions. Charge distributions are well localized, where localization is slightly weakened in the presence of magnetization. We have set \( m = \lambda = \Delta = t \).

The topological phase diagram, given in Fig.5(a), consists of a SOTI phase, Chern TI (CI) phases and trivial insulator phases. We can check there are chiral edge states for nanoribbons in the CI phase. We have also gap closing in the CI phase at \( E(\pi,0) = E(0,\pi) = 0 \) with \( E(\pi,0) = E(0,\pi) = \sqrt{m^2 + 4\Delta^2} \pm B \), \( -\sqrt{m^2 + 4\Delta^2} \pm B \), which are plotted in dotted curves in Fig.5(a).

Edge states: We calculate the band structure of nanoribbons without the Zeeman term in the topological phase \( |m/t| < 2 \). In the absence of the \( H_\Delta \) term, there are topological edge states as shown in Fig.5(b). They are gapped by the \( H_\Delta \) term as shown in Fig.5(c). Namely, edge states are absent since the rotoinversion symmetry \( C_4 \) is broken in the nanoribbon geometry.

Corner states: We calculate the eigenvalues of the Hamil-
tonian for a square nanodisk, which preserves the four-fold rotational symmetry. We show the eigenvalues in Fig.6(a1) and (a2) in the absence of the Zeeman term. There are four zero-energy states. These zero-energy states remain as they are even when the Zeeman term is introduced as in Fig.6(b1) and (a2). This is a 2D magnetic SOTI. We show the charge distribution in the absence and presence of the Zeeman term in Fig.6(a3) and (b3), respectively. The wave functions are localized at the four corners.

The origin of the gap opening in nanoribbon geometry and persistence of the corner states in the presence of the $H_{\Delta}$ term is naturally understood by treating the $H_{\Delta}$ as a perturbation.$^{20}$

The edge states at the zero energy are spatially uniform. The expectation value of the $H_{\Delta}$ term is $\Delta$ along the $x$ direction while it is $-\Delta$ along the $y$ direction. Thus, the edge states are gapped for a nanoribbon geometry. On the other hand, the expectation value of the $H_{\Delta}$ is exactly cancelled at the corner. As a result, the corner states are robust in the presence of $H_{\Delta}$ term.

3D second-order topological semimetals: By setting $m = m_0 + t_z \cos k_z$ in the 2D magnetic SOTI Hamiltonian, we can construct a model for 3D magnetic second-order topological semimetals in the similar way to the previous works.$^{22,25}$ The properties are derived by the sliced Hamiltonian $H(k_z)$ along the $k_z$ axis, which gives a 2D magnetic SOTI model with various mass term $m$. The bulk band gap closes at the points $k_z = \arccos((m - m_0)/t_z)$. The surface states are gapped except for the two bulk gap closing points. On the other hand, there emerge hinge-arc states connecting the two gap closing points, which are shown in Fig.7(a). This hinge-arc states are robust even in the presence of the Zeeman term as shown in Fig.7(b).

The author is very much grateful to N. Nagaosa for helpful discussions on the subject. This work is supported by the Grants-in-Aid for Scientific Research from MEXT KAKENHI (Grant Nos.JP17K05490 and JP15H05854). This work is also supported by CREST, JST (JPMJCR16F1).
