Abstract. We consider a model of weakly interacting close-packed dimers on the two-dimensional square lattice. In a previous paper, we computed both the multi-point dimer correlations, which display non-trivial critical exponents, continuously varying with the interaction strength; and the height fluctuations, which, after proper coarse graining and rescaling, converge to a massless Gaussian field with a suitable interaction-dependent pre-factor (‘amplitude’). In this paper, we prove the identity between the critical exponent of the two-point dimer correlation and the amplitude of this massless Gaussian field. This identity is the restatement, in the context of interacting dimers, of one of the Haldane universality relations, part of his Luttinger-liquid conjecture, originally formulated in the context of one-dimensional interacting Fermi systems. Its validity is a strong confirmation of the effective massless Gaussian field description of the interacting dimer model, which was proposed on the basis of formal bosonization arguments. We also conjecture that a certain discrete curve defined at the lattice level via the Temperley bijection converges in the scaling limit to an SLE\(_\kappa\) process, with \(\kappa\) depending non-trivially on the interaction and related in a simple way to the amplitude of the limiting Gaussian field.

1. Introduction

In recent years, there has been an increasing interest from the mathematical community in the conformal invariance properties of two-dimensional (2D) statistical systems at the critical point, and on their connections with the massless Gaussian field. The introduction of novel techniques, ranging from discrete holomorphicity \[12, 38, 39, 58\] to Schramm–Loewner evolution (SLE) \[44\] and percolation techniques \[62\], finally allowed, after more than 50 years of intense research, full characterization of the structure and the conformal invariance of dimer \[19, 40\] and Ising models \[14, 31\], as well as rigorous confirmation of some predictions, based on conformal field theory (CFT) arguments, concerning crossing probabilities in critical percolation \[59\]. These exciting advances are still ongoing and, as they develop, they are revealing a closer and closer connection between the lattice-integrability properties of dimer and Ising models, and certain CFT structures and objects, such as the Virasoro algebra, the operator product expansion, and the stress–energy tensor \[32\].

A big limitation of these methods is that they are mostly confined to models at the free-fermion point, and it is a major challenge to develop techniques for rigorously controlling the scaling limit of general interacting, non-integrable theories, and for proving their conformal covariance properties. A standard method used in quantum field theory (QFT) and condensed matter communities for quantitatively characterizing the scaling limit of 2D interacting theories at the critical point is the so-called Coulomb gas formalism, which is based on an effective description of several 2D critical theories in terms of a massless Gaussian field (‘bosonization method’) \[46, 54\]. In this approach, the conformal invariance of the interacting theory translates into the well-known conformal invariance of the Gaussian model. Most of the applications of this method are quite heuristic, and we are still lacking a full comprehension of the emergence of the massless Gaussian field in the scaling limit.

In this paper, we prove a rigorous instance of this emergent correspondence in the context of interacting dimer models, giving a strong justification of the use of the Coulomb gas description outside the free-fermion point. Our new result complements our previous findings in \[25\], where we showed that the critical exponent of the dimer–dimer correlations is an analytic function of the interaction strength, and proved the convergence, at large distances, of the height function to the massless Gaussian field, with a suitable interaction-dependent pre-factor. In short, our new result is a rigorous proof of the identity between such a pre-factor (the ‘stiffness’ or ‘amplitude’ of the massless Gaussian field) and the dimer–dimer critical exponent. This identity, very surprising at first sight, can be guessed on the basis of the aforementioned representation of the interacting dimer model in terms of a massless Gaussian field. It is an instance of the so-called Haldane relations, originally formulated in the context of one-dimensional interacting Fermi systems, as part of the famous Haldane’s Luttinger-liquid picture \[28, 29\].

Before formulating the model and the result precisely (see section 4), we first make a historical digression on the concept of Luttinger-liquid universality class and on the bosonization method, which may be useful for clarifying the motivations behind the emergence of an effective ‘massless Gaussian field’ behavior and the Haldane relation. We also explain the connection between these concepts and 2D dimer models.
### 1.1. Luttinger liquids

Kadanoff [34] and Haldane [28, 29] (see also [16, 35, 36, 46, 56]) conjectured the existence of a ‘universality class’, called the ‘8-vertex universality class’ or ‘Luttinger liquids’, of models whose low-energy behavior is described by a 2D massless Gaussian field (i.e. a free massless boson field) $\phi$ with covariance

$$\mathbb{E}(\phi(x)\phi(y)) = -\frac{A}{2\pi^2} \log|x-y|,$$

for a suitable constant $A$, which is model-dependent. In particular, the correlation functions of models in this class are, asymptotically at large distances, the same as those of suitable functions of $\phi$. Models in this class include 2D classical systems: the 6- (6V) and 8-vertex (8V) models, the Ashkin–Teller model, and interacting dimer models with close packing; and one-dimensional quantum systems: Heisenberg spin chains, the Luttinger model and the spinless Hubbard models (see [4, 28, 34, 46, 56]). This conjecture implies, in particular, that the critical exponents are connected by scaling relations such that, once a single exponent is known, all the others are determined, and that there are simple relations between the critical exponents and the ‘amplitudes’ (i.e. the pre-factors in front of the power-law decay) of suitable correlations. These predictions have mostly been checked in exactly solvable models, but they are also expected to hold for non-solvable ones.

### 1.2. Bosonization

The models in the Luttinger-liquid universality class that we mentioned describe interacting spins or particles; therefore, the mapping of all these systems into such a simple model as the massless Gaussian field is, at first sight, surprising. The simplest way to understand this correspondence is via the concept of ‘bosonization’, which is a crucial notion in 2D QFT and in condensed matter physics. The starting point is the observation that all the lattice models in the Luttinger-liquid universality class (vertex models, spin chains, dimers, Ashkin–Teller) admit an exact description in terms of lattice fermions, i.e. a family of Grassmann variables $\psi_{x,\sigma,\omega}$, indexed by lattice vertices $x = (x_1, x_2)$, as well as by two indices $\sigma, \omega = \pm$. For instance, the 8-vertex and the Ashkin–Teller models can be represented as a pair of 2D Ising models coupled via a quartic interaction [4], and the fermionic representation is inherited from the Pfaffian description of the 2D Ising model. For special values of the model parameters (free-fermion point) such fermions are non-interacting and then the system is exactly solvable. However, for generic values of the parameters the fermions are interacting, i.e. their action contains terms at least quartic in the Grassmann variables, so that the partition function and the correlations are given by non-Gaussian Grassmann integrals. If one performs a formal continuum limit, such fermions becomes Dirac fermions in $d = 1 + 1$ dimensions, which are massless at criticality.

There is a well-known correspondence in $d = 1 + 1$ QFT between bosons and fermions [15]. Take non-interacting massless Dirac fermions $\psi_{x,\sigma,\omega}$, $\sigma, \omega = \pm$, $x \in \mathbb{R}^2$, with a propagator that is diagonal in the index $\omega$, anti-diagonal in $\sigma$, translation-invariant in $x$ and such that

https://doi.org/10.1088/1742-5468/aa5d1f
Haldane relation for interacting dimers

\[ \langle \psi_{x,\omega}^+ \psi_{0,\omega}^+ \rangle = \frac{C_\omega}{x_1 + i\omega x_2}, \]  
(1.2)

with \( C_\omega \) constants such that\(^4\) \( C_\omega = C_{\omega+}^\ast \). Then, bosonization consists of the following two identities (see e.g. [17]):

- the ‘fermionic density’ \( \psi_{x,\omega}^+ \psi_{x,\omega}^- \) has the same multi-point correlations as the derivative of a boson field:
  \[ \psi_{x,\omega}^+ \psi_{x,\omega}^- \leftrightarrow 2i\pi C_\omega \partial \phi, \]  
(1.3)

where \( \partial \omega := \frac{1}{2}(\partial_{x_1} - i\omega \partial_{x_2}) \), and \( \phi \) is the massless Gaussian field with covariance (1.1) with \( A = 1 \). In particular, correlations of \( \psi_{x,\omega}^+ \psi_{x,\omega}^- \) of odd order and truncated correlations of order larger than 2 vanish.

- the ‘fermionic mass’ \( \psi_{x,\omega}^+ \psi_{x,-\omega}^- \) has the same correlations as a normal-order exponential of the boson field:
  \[ \psi_{x,\omega}^+ \psi_{x,-\omega}^- \leftrightarrow C_\omega e^{2i\pi \omega \phi(x)} :, \]  
(1.4)

where \( : \cdots : \) denotes Wick ordering (see e.g. [17]).

Remarkably, a similar correspondence also remains valid [15] for interacting massless Dirac fermions. In particular, in the presence of a local, delta, interaction (Thirring model) of the multi-point correlations of the fermionic density and fermionic mass operators are known explicitly [33, 43, 60] and the bosonization identities are still true, provided that the left-hand side of (1.4) is divided by a suitable renormalization constant, diverging in the ultraviolet limit. Moreover, the pre-factor \( A \) in (1.1) is changed into an interaction-dependent constant, \( A = A(\lambda) = 1 \), where \( \lambda \) is the strength of the delta interaction. Note that the density and mass operators in the Thirring model are naturally defined up to multiplicative renormalization constants, whose specific choices are part of the definition of the model. In this sense, the amplitudes of the fermionic operators (which play a role in the Haldane relations that we are interested in) are somewhat ambiguous; therefore, it would be desirable to have at our disposal a solvable model (similar to Thirring, but free of ultraviolet divergences) to be used to unambiguously test the desired universality relations between amplitudes and critical exponents.

The simplest such model is a model of interacting massless Dirac fermions, whose interaction is local, and delta-like, only in one of the two directions, say horizontal (Luttinger model). Additionally, in this case the correlations can be computed exactly [49] and, for a proper choice of the bare Fermi velocity (chosen in such a way that the interacting Fermi velocity is 1), their asymptotic expression at large distances reads:

\[ \sum_\omega \langle \psi_{x,\omega}^+ \psi_{x,\omega}^- ; \psi_{0,\omega}^+ \psi_{0,\omega}^- \rangle \approx \frac{A}{2\pi^2} \frac{x_1^2 - x_2^2}{|x|^4}, \]  
(1.5)

\(^4\) A standard choice is \( C_\omega = 1/(2\pi) \). However, for the interacting dimer model, below we consider a natural choice of coordinates, which leads to \( C_\omega = \omega \) depending on \( \omega \). We could reduce to the standard case via a suitable rotation of space coordinates, but then many formulas would look more cumbersome.
and

\[ \sum_{\omega} \langle \psi_{x,\omega}^+ \psi_{x,-\omega}^-; \psi_{0,-\omega}^+ \psi_{0,\omega}^- \rangle \simeq \frac{B}{2\pi^2 |x|^2} \frac{1}{\omega} \]  

(1.6)

where the semicolon indicates truncated expectation, and \( A \) and \( B \) are suitable interaction-dependent constants. Equation (1.5) and (1.6) are the same that one would obtain by using (1.3) and (1.4), with \( \phi \) normalized as in (1.1) and \( C_\omega = 1/(2\pi) \), provided the right-hand side of (1.4) is multiplied by \( \sqrt{B} \). Note that the constant \( A \) in (1.5) is the same as the one appearing in the critical exponent in (1.6). The same identity between the amplitude of the density–density correlations and the critical exponent of the mass–mass correlations has been verified for other exactly solvable models in the same universality class; in particular, for the XXZ spin chain [28]. The conjecture is that it should also remain valid for models that are not exactly soluble in the same universality class, including lattice models, for which an exact mapping into a massless Gaussian field is not possible.

1.3. Previous results

In the absence of exact solutions or of bosonization identities, the computation of the asymptotic behavior of correlations at criticality, not to mention the verification of the Kadanoff–Haldane relations, is a major mathematical challenge. Constructive QFT and renormalization group (RG) techniques provide powerful mathematical tools to attack these problems. These methods allowed one of us [48] to prove that the critical exponents of the 8-vertex and the Ashkin–Teller model, close to the free-fermion point, are analytic functions of the interaction strength \( \lambda \). Benfatto, Falco and Mastropietro [6] later extended the analysis of [48], proving the validity of some of the Kadanoff relations between the critical exponents of several non-integrable models in the 8-vertex universality class, as well as two Haldane relations between exponents and amplitudes for a quantum spin chain [9, 10]. These results provide relations only between correlations of quantities that are local in the fermionic variables. An important open problem is analysis of the observables that are non-local instead, such as the spin in coupled Ising layers and the height function in dimer models. The analysis of these observables is already very non-trivial at the free-fermion point [14, 19, 20, 39, 40].

1.4. Interacting dimers

Motivated by these issues, in [25, 26] we considered a non-integrable dimer model with close packing on \( \mathbb{Z}^2 \), where dimers interact via a short-range potential of strength \( \lambda \). We studied two natural observables: the dimer occupation variable \( 1_e \), indexed by edges \( e \) of the square lattice, and the height function \( h(\eta) \), indexed by faces \( \eta \). The model can be rewritten (see section 3.3 below) as a system of 2D interacting lattice Dirac fermions with a propagator behaving at large distances as in (1.2) with \( C_\omega = 1/(2\pi(1-\omega)) \) (see (3.24)). When the coupling parameter \( \lambda \) is set to zero the fermion–fermion interaction vanishes, corresponding to the Pfaffian nature of Kasteleyn’s solution of the non-interacting dimer model. The observable \( 1_e \) has a local expression \( \mathcal{I}_e \) in the fermionic representation, containing both a ‘density term’ \( \psi_{x,\omega}^+ \psi_{x,\omega}^- \) and a ‘mass term’ \( \psi_{x,\omega}^+ \psi_{x,-\omega}^- \).
where the latter is multiplied by a pre-factor that oscillates with distance. If, e.g. \( e \) is horizontal, then (if \( x = (x_1, x_2) \) is the coordinate of the edge \( e \) and \((-1)^x = (-1)^{x_1 + x_2}\))

\[
\mathcal{I}_e = \pm \sum_{\omega} \left[ \psi_{x_1,\omega}^+ \psi_{x_1,\omega}^- + (-1)^x \psi_{x_1,\omega}^+ \psi_{x_1,\omega}^- \right] + \text{h.o.},
\]

where the sign in front depends on the parity of the edge, and h.o. indicates subdominant terms\(^5\): see below for the full expression (see in particular remark 4). The height function \( h(\eta) \) is defined as the sum over a lattice path \( \eta_0, \eta_1, \ldots, \eta_k = \eta \), from a reference face \( \eta_0 \) to \( \eta \), of \( \sigma_{(x_1 - 1/4)} \), with \( \sigma \) a suitable sign (see (2.6) and following lines) and, therefore, by (1.7), it is non-local in the fermionic variables.

Using (1.7), one finds that the dimer–dimer correlation \( \langle 1_e; 1_{e'} \rangle \) is the sum of two terms, the first corresponding to a density–density correlation,

\[
\sum_{\omega} \langle \psi_{x_1,\omega}^+ \psi_{x_1,\omega}^-; \psi_{x_1',\omega}^+ \psi_{x_1',\omega}^- \rangle
\]

and the second to a mass–mass correlation with oscillating pre-factor:

\[
(-1)^{x + x'} \sum_{\omega} \langle \psi_{x_1,\omega}^+ \psi_{x_1,\omega}^-; \psi_{x_1',\omega}^+ \psi_{x_1',\omega}^- \rangle.
\]

By heuristically using the bosonization identities (1.3) and (1.4), one guesses that (1.8) should behave asymptotically as

\[
\frac{A}{2\pi^2} \text{Re} \left( \frac{1}{(1 - i)^2(z - z')^2} \right),
\]

with \( z = x_1 + i x_2, z' = x_1' + i x_2' \), while (1.9) should be asymptotically proportional to

\[
(-1)^{x + x'} \frac{1}{|z - z'|^{2\nu}},
\]

with \( \nu = A \). Similarly, by using the fermionic representation of the height function and the first bosonization identity (1.3), one predicts that \( h(\eta) \) tends to a massless Gaussian field with covariance (1.1), and the same \( A \) as in (1.10).

In [25, 26], we developed a renormalization group analysis for the interacting dimer model, which allowed us to prove most of these predictions, in particular the convergence of the height field to the massless Gaussian field, the validity of (1.10) and (1.11) and their multi-point generalization. However, the important question of the identity \( A = \nu \) was not addressed, and we prove it here by combining the ideas of [25, 26] together with a comparison of exact lattice Ward identities with those of a relativistic reference model, in the spirit of [9, 10]. The remarkable identity \( A = \nu \) is a strong confirmation of the validity of the massless Gaussian-field description of the interacting dimer model. It is a restatement of the Haldane relation between the ‘compressibility’ and the ‘density–density critical index’, in a context different from the one originally proposed by Haldane, who considered interacting fermions in one dimension and quantum spin chains: in this sense, it is the first example of such a universality relation in a classical statistical mechanics model.

\(^5\) By ‘subdominant’ here we mean contributions that produce faster decaying terms at large distances in the computation of \( \langle \mathcal{I}_e; A_{e'} \rangle \), where \( A_{e'} \) is an observable localized around the bond \( e' \), and \( |e - e'| \gg 1 \).
1.5. Summary

The rest of the paper is organized as follows. In section 4 we define the model precisely and state our main results. We also comment on possible generalizations to related models and about the possible emergence, in the scaling limit, of an SLE\(_\kappa\) process with \(\lambda\)-dependent diffusion constant \(\kappa\), underlying the interacting dimer model. The following sections contain the technical aspects of the proof of our main theorem, in particular:

- In section 3 we discuss the Grassmannian formulation of the model;
- In section 4 we derive a lattice Ward identity for the dimer model, which plays an important role in the proof of the Haldane relation;
- In section 5 we introduce a relativistic continuum model (the ‘reference model’), which plays the role of the infrared fixed point of the dimer model, and review some of the properties of its correlations;
- In appendix A we put together the ingredients of the previous sections to complete the proof of the Haldane relation; in appendix B we compare the notations and conventions of the present paper with those of [25].

In the appendices we explore a few more technical issues: in appendix A we discuss the structure of the singularities of the Fourier transform of the dimer–dimer correlations; in appendix B we verify the Haldane relation at first order in perturbation theory; in appendix C we review the derivation of the Ward identities for the relativistic reference model, as well as the exact computation of its two- and four-point functions.

2. Model and result

Let us now define our model more precisely. We consider the bipartite graph \(\mathbb{Z}^2\), and we decompose it into two sublattices (black/white sublattices \(V_B/V_W\)) such that all neighbors of a vertex \(v \in V_B\) belong to \(V_W\) and vice versa. Each vertex is assigned a coordinate \(x = (x_1, x_2)\) and a white vertex has the same coordinates as the black vertex just to its left. Both \(V_B\) and \(V_W\) will be thought of as Bravais lattices with basis vectors \(\vec{e}_1\) and \(\vec{e}_2\), where \(\vec{e}_1\) is the vector of length \(\sqrt{2}\) and angle \(-\pi/4\) w.r.t. the horizontal axis, while \(\vec{e}_2\) has a length of \(\sqrt{2}\) and an angle of \(+\pi/4\) (see figure 1).

Given an edge \(e\), we let \(b(e), w(e)\) denote the black/white vertex of \(e\). Edges are of four different types: \(r = 1, 2, 3, 4\). We say that \(e\) is of type \(r\) if the vector from \(b(e)\) to \(w(e)\) forms an anti-clockwise angle \((r - 1)\pi/2\) with respect to the horizontal axis. An edge \(e\) is unambiguously identified by its type \(r(e)\) and by the coordinates \(x(e) = (x_1(e), x_2(e))\) of its black site.

We consider the dimer model in a periodic box: we let \(\mathbb{Z}_L\) be the graph \(\mathbb{Z}^2\) periodized (with period \(L\)) in both directions \(\vec{e}_1, \vec{e}_2\) (see figure 1). With a slight abuse of notation, we still denote the set of white/black sites of \(\mathbb{Z}_L\) by \(V_W, V_B\), without making the \(L\) dependence explicit. Black/white sites are, therefore, indexed by coordinates \(x \in \Lambda = \Lambda_L = \{(x_1, x_2), 1 \leq x_i \leq L\}\).
The partition function of the interacting dimer model we study is
\[
Z_{\lambda, m} = \sum_{M \in \mathcal{M}_L} \left( \prod_{e \in M} t_e^{(m)} \right) e^{\lambda H_L(M)} =: \sum_{M \in \mathcal{M}_L} p_{\lambda; \lambda, m}(M) \tag{2.1}
\]
where

- \( \mathcal{M}_L \) is the set of perfect matchings of \( \mathbb{T}_L \);
- \( H_L(M) \) is the number of square plaquettes of \( \mathbb{T}_L \) containing two parallel dimers;
- \( \lambda \) is a real parameter (coupling constant);
- \( m > 0 \) and

\[
t_e^{(m)} = 1 + m(-1)^{x_1(e)+x_2(e)}(\delta_{r(e)=1} - \delta_{r(e)=3}). \tag{2.2}
\]

As discussed in [25], the parameter \( m \geq 0 \) (the mass) plays the role of an infrared cut-off, to eventually be sent to zero: it has the effect that correlations decay exponentially with distance (uniformly in \( L \)) as long as \( m > 0 \), and it is sent to zero after the thermodynamic limit \( L \to \infty \). This model, in the limit \( m \to 0 \), describes polar crystals [30] and it was recently reconsidered in [2, 55] in connection with quantum dimer models.

The Boltzmann–Gibbs measure associated with the model is denoted by \( \langle \cdot \rangle_{\lambda; \lambda, m} \): if \( O(M) \) is a function of the dimer configuration,
\[ \langle O \rangle_{\lambda; \nu} := \frac{1}{Z_{\lambda}(\nu)} \sum_{M \in \mathcal{M}_L} p_{\lambda; \nu}(M) O(M). \] (2.3)

**Remark 1.** This model is the same as that studied in [25, 26]. However, here we use a different convention for the coordinates on the lattice, which respects the bipartite structure and turns out to be convenient for the derivation of the Ward identities. In order to restate the results derived here in the notations of [25], one needs to properly redefine the coordinates, with the conventions of [25, 26], the black (resp. white) site of coordinate \( x = (x_1, x_2) \) have coordinates \( \tilde{x}(x) \) (resp. \( \tilde{x}(x) + (1, 0) \)), where

\[ \tilde{x}(x) = (x_1 + x_2, x_2 - x_1). \] (2.4)

As discussed in [25], whenever \( O \) is a bounded local function, the following limit exists:

\[ \langle O \rangle_\lambda := \lim_{m \to 0} \lim_{L \to \infty} \langle O \rangle_{\lambda; \nu}, \] (2.5)

and defines a translationally invariant infinite-volume Gibbs state \( \langle \cdot \rangle_\lambda \).

When \( \lambda = 0 \) (non-interacting model) the model is well known to be exactly solvable via Kasteleyn’s theory [37], in the sense that \( n \)-point correlations can be computed explicitly as determinants. When both \( \lambda \) and \( m \) are zero (non-interacting and massless model) the partition function reduces to the cardinality of \( \mathcal{M}_L \).

Before stating our main result, let us briefly review what was proven in [25]. We can recall that the height function is defined by fixing it to zero at some reference face \( \eta_0 \), and by establishing that

\[ h(\eta) - h(\xi) = \sum_{e \in C_{\xi \to \eta}} \sigma_e(1 - 1/4), \] (2.6)

with \( C_{\xi \to \eta} \) any nearest-neighbor path from \( \xi \) to \( \eta \), the sum running over the edges crossed by the path, \( \sigma_e \) the indicator function that an edge of \( \mathbb{Z}^2 \) is occupied by a dimer and \( \sigma_e \) being +1 or −1 according to whether the edge is traversed with the white vertex on the right or left. The content of [25, theorems 1 and 3] is that there exists \( \lambda_0 > 0 \) such that, if \( |\lambda| < \lambda_0 \) then the height field associated to the dimer configuration converges in distribution, in the scaling limit, to a massless Gaussian field \( \phi(\cdot) \) on the plane, with covariance

\[ \mathbb{E}(\phi(x)\phi(y)) = -\frac{A(\lambda)}{2\pi^2} \log|x - y|, \] (2.7)

where\(^6\) \( A(\lambda) \) is an analytic function of \( \lambda \) satisfying \( A(0) = 1 \). More precisely, for any smooth, zero-average test function \( f \) on \( \mathbb{R}^2 \), the random variable

\[ \epsilon^2 \sum_{\eta} h(\eta)f(\epsilon \eta) \]

converges in distribution, in the limit \( \lim_{\epsilon \to 0} \lim_{m \to 0} \lim_{L \to \infty} \), to

\(^6\) The constant \( A(\lambda) \) was called ‘\( K(\lambda) \)’ in [25]. Here, we change notation in order to avoid confusion with the elements of the Kasteleyn matrix, which is traditionally denoted by \( K \).

https://doi.org/10.1088/1742-5468/aa5d1f
Moreover, the \( n \)th cumulant of \( h(\eta) - h(\xi), n \geq 3 \), is bounded uniformly in \( \eta, \xi \).

A crucial ingredient in the proof was a sharp asymptotic expression for dimer–dimer correlations. The rewriting of [25, theorem 2] with the present convention gives the following: There exist real analytic functions \( B(\cdot), \nu(\cdot) \), defined in a neighborhood \( |\lambda| \leq \lambda_0 \) of the origin, satisfying \( B(0) = \nu(0) = 1 \), such that the following holds. Let \( e, e' \) be edges of type \( r, r' \), with \( b(e) = x = (x_1, x_2) \neq 0 \) and \( b(e') = 0 \). Then, for \( |\lambda| \leq \lambda_0 \),

\[
\langle 1_e; 1_{e'} \rangle_\lambda = -\frac{A(\lambda)}{2\pi^2} \text{Re} \left[ \frac{e^{i\pi(r+r')}}{(1 - i)^2(x_1 + ix_2)^2} \right] + t_{r,r'} \frac{B(\lambda)}{4\pi^2} (-1)^{z_1+z_2} \frac{1}{|x|^{2\nu(\lambda)}} + R_{r,r'}(x) \tag{2.8}
\]

where

\[
|R_{r,r'}(x)| \leq C_0 (1+|x|)^{-2-\theta} \tag{2.9}
\]

for some \( 1/2 \leq \theta < 1 \), \( C_0 > 0 \), and \( t_{r,r'} \) is 1 if \( r = r' \), 0 if the two edges are not parallel, and \(-1\) if they are parallel, but not of the same type. The function \( A(\cdot) \) is the same as in (2.7). The first line of (2.8) coincides with the right-hand side of (1.10) for \( r = r' = 1 \) and \( z' = 0 \).

Note that the large-scale behavior of the height field depends only on \( A(\cdot) \) and not on \( B(\cdot), \nu(\cdot) \). Observe also that the decay at large distances of the dimer–dimer correlation is controlled by the critical exponent \( \min(2, 2\nu(\lambda)) \).

The main result of the present work is an identity between the limit variance \( A(\lambda) \) of the height field and the dimer–dimer critical exponent \( \nu(\lambda) \).

**Theorem 1.** There exists \( \lambda_0 \) such that, if \( |\lambda| \leq \lambda_0 \), then (2.8) holds with

\[
A(\lambda) = \nu(\lambda) \tag{2.10}
\]

This result confirms the predictions of the universality conjecture of Kadanoff and Haldane for this model, as discussed in the Introduction. It would be interesting to apply the methods of its proof to the computation of other universality relations, such as the relation between the sub-leading corrections to the free energy of the interacting dimer model and the central charge \([1, 11]\), in the spirit of [24].

**Remark 2 (First-order computation).** While the non-perturbative proof of theorem 1 (sections 4–7) requires the use of lattice Ward identities and a comparison with a continuum model, one can directly check (2.10) at low orders in perturbation theory. In appendix B we check the equality at first order in \( \lambda \), via an explicit computation of the lowest-order Feynman diagrams. Remarkably, even at lowest order, this equality requires non-trivial cancellations between Feynman diagrams. As a byproduct of appendix B, we find that

\[
A(\lambda) = \nu(\lambda) = 1 - \frac{4}{\pi} \lambda + O(\lambda^2). \tag{2.11}
\]
In view of (1.1), this shows that when the dimer–dimer interaction $\lambda H_L$ is attractive ($\lambda > 0$), the variance of height fluctuations decreases (the interface is more rigid) and dimer–dimer correlations decay slower. This is compatible with the fact that at large enough $\lambda$ the model is known to have a rigid, crystalline, phase, which is characterized by a long-range order of ‘columnar’ type and $O(1)$ height fluctuations [30].

2.1. Outlook and conjectures

2.1.1. Extensions to other models. As discussed in [25], the specific form of the interaction in (2.1) is unimportant for the validity of the massless Gaussian behavior of the height function: see remark 3 after theorem 3 in [25]. Similarly, it is unimportant for the validity of the Haldane relation (2.10): the same identity holds true for a wide class of interacting dimer models, whose interaction is weak, of finite range, and symmetric under the natural lattice symmetries of $\mathbb{Z}^2$ (translations, reflections, discrete rotations). Both the results of [25] and those of the present paper are presumably valid also for other closely related models, in particular, for the 6V model, which is known to be equivalent to an interacting dimer model on $\mathbb{Z}^2$ with a plaquette interaction proportional to the number of even faces of $\mathbb{Z}^2$ with two parallel dimers (see [3, 22]). Note that the mapping of the 6V model into such an interacting dimer model preserves the height function, up to a factor $1/2$: the height function of the 6V model (defined as in [61]) equals half the height function of the dimer model, restricted to faces of odd parity (see the comment after equation (7) of [22]). The plaquette interaction of the effective dimer representation of the 6V model, acting only on even faces, is not invariant under the full group of translations; therefore, it has a slightly different symmetry to the one of the model considered in the present paper and in [25]. It is likely that such a change is unimportant for the proofs in [25]. The explicit verification that such a modified symmetry neither changes the structure of the effective infrared theory, nor the structure of the Ward identities, will be discussed elsewhere.

2.1.2. Emergent SLE. The emergent description of the interacting dimer model in terms of a massless Gaussian field calls for the emergence of an SLE process, dual to the Gaussian field. In fact, at the continuum level, there are several known connections, or ‘couplings’, between these two types of stochastic processes [13, 18, 50–53, 57]. Inspired by these results, we conjecture that a microscopic geometric curve, associated with the Temperley spanning forest, defined below, converges in the scaling limit to a variant of the space-filling SLE\(\kappa'\) process, with $\kappa' > 4$ the largest root of

$$A(\lambda) = \frac{2\kappa'}{(4 - \kappa')^2}. \quad (2.12)$$

Note that, if $\lambda = 0$ (in which case $A = A(0) = 1$), then $\kappa' = 8$.

Here, we give some support to this conjecture. The starting point is the Temperley bijection: see, for instance, [21, 42]. Given a dimer configuration on $\mathbb{T}_L$, for every

---

\(^7\) Given the speculative nature of the discussion, we are purposely a bit sloppy on the precise nature of the limiting SLE, as well as on the role played by the boundary conditions. The ‘variant’ of SLE we refer to is described in detail in [50–53].
white vertex \( w \) of even parity, we can draw an oriented edge of length 2 from \( w \) that goes along the unique dimer with an endpoint at \( w \) (such an edge, of course, ends at another white vertex \( w' \) of the same parity). The collection of edges thus drawn forms a cycle-rooted spanning forest (CRSF): every connected component contains an oriented cycle and the other edges in the same component form trees oriented toward the cycle, to which they are rooted. This CRSF spans the sub-graph of \( T_L \) induced by white vertices of even parity: see figure 2 where the CRSF, that in this example has a single connected component, is drawn in red. Repeating the same construction with white edges of odd parity one obtains a ‘dual’ CRSF (drawn in blue in figure 2).

Finally, one can draw an oriented wiggly curve \( \Gamma \) that runs between the primary and dual CRSF (in figure 2 this curve has two connected components, drawn in different colors). Note that the curve \( \Gamma \) passes once through every face of \( L_T \). We use the convention that, at the center of each face, \( \Gamma \) is tangent to one of the two main diagonals of the square lattice.

There is a simple correspondence between the height function and the curve \( \Gamma \), as the reader may verify by comparing figures 2 and 3. If \( \eta_1 \) and \( \eta_2 \) are two faces, which the same connected component of \( \Gamma \) passes through, the combination \( 2\pi[h(\eta_2) - h(\eta_1)] \) is the net amount of winding of \( \Gamma \) between \( \eta_1 \) and \( \eta_2 \). Moreover, such a condition on the winding determines the curve \( \Gamma \) uniquely.

In the non-interacting case (\( \lambda = 0 \)), it has been proven \cite{45} that the curve \( \Gamma \) tends (in the scaling limit) to a variant of SLE\( _{8} \). In the interacting case, we conjecture that \( \Gamma \) converges to (a variant of) SLE\( _{\kappa'} \), with \( \kappa' \) the largest root of (2.12). The conjecture is
based on the series of works [50–53] (notably, see [53]), where the authors, directly and at the continuum level, give a meaning to the notion of a solution of the differential equation

\[ \gamma(t) = e^{i(2\pi \phi(\gamma(t)) + \theta)}, \] (2.13)

where \( \phi \) is a massless Gaussian field with covariance (2.7), and \( \theta \) a real constant. Note that the flow line \( \gamma(t) \), the solution of (2.13), is such that \( 2\pi [\phi(\gamma(t)) - \phi(\gamma(0))] \) describes the net amount of winding of \( \gamma(t) \) around the circle between times 0 and \( t \). In [50–53] the authors define a continuous tree whose branches, roughly speaking, are the solutions of (2.13) starting from any point on the plane; and a space-filling curve that traces the tree in the natural order. They prove\(^8\) that the latter defines a space-filling SLE\( \kappa' \) process, with \( \kappa' \) the largest root of (2.12): this space-filling curve is the continuous

\(^8\) In [53] the authors use a different convention, namely they study the solution of \( \gamma(t) = e^{i\phi(\gamma(t)) + \chi + \theta} \), with \( \phi \) the massless Gaussian field with covariance \(- \log |x - y|\), and they prove that it defines a space-filling SLE\( \kappa' \) process, with \( \kappa' \) and \( \chi \) related by \( \chi = \sqrt{\kappa'}/2 - 2i\sqrt{\kappa'} \). Using the fact that \( \varphi = \sqrt{(2\pi^2/A)}\phi \), we find that \( \chi = \sqrt{\kappa A} \) and we see that the relation between \( \chi \) and \( \kappa' \) implies (2.12).

https://doi.org/10.1088/1742-5468/aa5d1f
Haldane relation for interacting dimers

analog of our space-filling discrete curve $\Gamma$, which leads to our conjecture. In [53], it is also proved that the flow lines $\gamma$ define a branched version of an SLE$_\kappa$ process, with $\kappa$ the diffusion constant ‘dual’ to $\kappa'$, i.e. $\kappa = 16/\kappa' < 4$: this branched process is the continuous analog of the Temperley CRSF; therefore, we also conjecture that the Temperley CRSF tends, in the scaling limit, to the variant of SLE$_\kappa$ described in [53].

Additionally, let us mention that recently a similar conjecture has been formulated (and successfully tested numerically) in [41] for the 6V model that, as recalled above, can be equivalently described in the form of an interacting dimer model. However, the discrete ‘space-filling’ curve considered in [41] is different from $\Gamma$. In particular, at the free-fermion point (that corresponds to $\lambda = 0$ for dimers) the curve of [41] converges to SLE$_{8 + 4 \sqrt{3}}$ rather than SLE$_8$.

3. Generating function and fermionic representation

In this section, we discuss the fermionic representation of the dimer model, which is the basis of the multi-scale expansion used in the proof of theorem 1.

The generating function of dimer correlations is defined as

$$
e^{-\mathcal{W}(A)} = \langle \prod_{e \in \Lambda} e^{A_e \lambda_e} \rangle_{\Lambda; \lambda, m},$$

(3.1)

where for each edge $e$, $A_e$ is a real number. In particular, the dimer–dimer correlation function in the thermodynamic and zero-mass limits is

$$G_{r, r'}^{(0, 2)}(x, y) := \lim_{m \rightarrow - \infty} \lim_{L \rightarrow \infty} \partial_{A_r, A_{r'}}^2 \mathcal{W}(A)|_{A = 0}$$

(3.2)

where $e, e'$ are the bonds of type $r, r'$ with $b(e) = x, b(e') = y$. Note that $G_{r, r'}^{(0, 2)}(x, y)$ depends only on $x - y$ and its Fourier transform is defined via

$$G_{r, r'}^{(0, 2)}(x, 0) = \int_{[-\pi, \pi]} \frac{dp}{2\pi} e^{ipx} G_{r, r'}^{(0, 2)}(p).$$

(3.3)

As discussed in [25, section 2], since we are working on the torus, the generating function at finite volume can be rewritten as the sum of four Grassmann integrals (the same way as the partition function of the non-interacting model on the torus is written in Kasteleyn’s theory as the sum of four determinants or Pfaffians [37]). However, since the mass $m$ is removed after the thermodynamic limit is taken, one can reduce to a single Grassmann integral (see [25, section 2.4]), the structure of which is discussed in the following sections.

3.1. Kasteleyn matrix and non-interacting model

Let us start by defining the Kasteleyn matrix $K$: this is a square matrix with rows/columns indexed by elements of $\Lambda$. If the black site $b_x$ of coordinate $x$ is not a neighbor of the white site $w_y$ of coordinate $y$, then we set $K(x, y) = 0$. Otherwise, if $b_x, w_y$ are the endpoints of an edge of type $r$, we set
\[ K(x, y) := K_r t^{(m)}_{(b, w)}, \quad K_r = e^{\frac{\pi}{2} (r - 1)} \]

where \( t^{(m)}_e \) was defined in (2.2). Given an edge \( e \) such that \( b(e) = x, w(e) = y \), we will write \( K(e) := K(x, y) \).

The matrix \( K \) is invertible as long as \( m > 0 \) and can be explicitly inverted in the Fourier basis. One has the following properties (these properties were discussed in detail in \([25, \text{section 2 and appendix A}]\), except that there we used a different coordinate system on \( \mathbb{Z}^2 \) (see remark 1), which explains why e.g. (3.5) below looks, at first sight, different from the \( m \to 0 \) limit of \([25, \text{equation (2.18)}]):

- If \( m > 0 \) is fixed, then \( K^{-1}(x, y) \) decays exponentially in \( |x - y| \) on a characteristic length of order \( 1/m \), uniformly in \( L \).
- If \( x, y \) is fixed, one has

\[
\lim_{m \to 0} \lim_{L \to \infty} K^{-1}(x, y) = g(x - y) := \int_{[-\pi, \pi]^2} \frac{dk}{(2\pi)^2} \frac{e^{-ik(x-y)}}{\mu(k)} (3.5)
\]

where

\[
\mu(k) = 1 - e^{ik_1 + k_2} + ie^{ik_1} - ie^{ik_2}. (3.6)
\]

- \( g(x - y) \) has the following long-distance behavior:

\[
g(x - y) \mid_{|x - y| \to \infty} \approx \frac{1}{2\pi} \left[ \frac{1}{a(x - y)} + \frac{(-1)^{x - y}}{a^*(x - y)} \right] + O(|x - y|^2) (3.7)
\]

where

\[
a(z) = (1 - i)z_1 + (1 + i)z_2. (3.8)
\]

The only zeros of \( \mu(\cdot) \) on \([-\pi, \pi]^2\) are \((k_1, k_2) = (0, 0) := p^+\) and \((k_1, k_2) = (\pi, \pi) := p^-\) and these are simple zeros:

\[
\mu(k) = D_\omega(k - p^\omega) + O(|k - p^\omega|^2), \quad \omega = \pm, (3.9)
\]

\[
D_\omega(k) = (-i - \omega)k_1 + (-i + \omega)k_2. (3.10)
\]

In order to represent the generating function \( \mathcal{W}_\Lambda(A, 0) \) as a Grassmann integral, we associate a Grassmann variable \( \psi_x^+ \) with the black vertex indexed \( x \in \Lambda \), and a Grassmann variable \( \psi_x^- \) with the white vertex indexed \( x \). For the sake of brevity, let \( \psi \) denote the collection of Grassmann variables \( (\psi_x^+, \psi_x^-)_{x \in \Lambda} \) with anti-periodic boundary conditions on \( T_L \), i.e. \( \psi_{x+L}^\pm = -\psi_x^\pm \), for all \( x \in \Lambda \) and \( j = 1, 2 \). Additionally, let \( \mathcal{E}_{0,\Lambda}(\cdot) \) be the Grassmann Gaussian ‘measure’ with propagator

\[
\mathcal{E}_{0,\Lambda}(\psi_x^+ \psi_y^-) := \int [\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-] e^{-(\psi_x^+ K_0 \psi_x^-)} \psi_x^+ \psi_y^- \frac{1}{\det(K_0)} = g_\Lambda(x - y), (3.11)
\]
Haldane relation for interacting dimers

\[ \mathcal{E}_{0,\Lambda}(\psi_x^- \psi_y^-) = \mathcal{E}_{0,\Lambda}(\psi_x^+ \psi_y^+) = 0. \] (3.12)

where \( K_0 \) is the Kasteleyn matrix with \( m = 0 \) and anti-periodic boundary conditions,

\[ g_\lambda(x) = K_0^{-1}(x,0) = \frac{1}{L^2} \sum_{k \in \mathcal{D}_\lambda} e^{-ikx} \] (3.13)

and

\[ \mathcal{D}_\Lambda = \{ k = (k_1, k_2) : k_i = \frac{2\pi}{L} (n_i + 1/2), 0 \leq n_i \leq L - 1 \}. \] (3.14)

We refer to [23, section 4] for a few basic facts on Grassmann integration. Here, let us just recall the fermionic Wick rule:

\[ \mathcal{E}_{0,\Lambda}(\psi_{x_1}^+ \psi_{y_1}^+ \cdots \psi_{x_n}^+ \psi_{y_n}^-) = \det G_\lambda(x, y), \] (3.15)

where \( G_\lambda(x, y) \) is the \( n \times n \) matrix with elements \( [G_\lambda(x, y)]_{ij} = g_\lambda(x_i - y_j), i, j = 1, \ldots, n \).

In the following, we shall denote the weak limit of \( \mathcal{E}_{0,\Lambda} \) as \( L \to \infty \) by \( \mathcal{E}_0 \).

Given a bond \( e = (b,w) \), we let \( E_e = K_0(e)\psi_{\psi^e} \psi_{\psi^e} \), so that

\[ (\psi^+, K_0\psi^-) = \sum_{x,y \in \Lambda} \psi_x^+ K_0(x, y)\psi_y^- = \sum_e E_e. \] (3.16)

The non-interacting generating function, in the thermodynamic and zero-mass limits, can be rewritten as

\[ \lim_{m \to 0} \lim_{L \to \infty} W_\Lambda(A)|_{\lambda=0} = \lim_{L \to \infty} W_\Lambda(A)|_{\lambda=0}, \] (3.17)

where

\[ W_\Lambda(A)|_{\lambda=0} = \log \frac{\int [\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-] e^{-\sum E_e e^A}}{\int [\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-] e^{-\sum E_e}} \] (3.18)

is the Grassmann generating function. By differentiating with respect to \( A_{e_1}, \ldots, A_{e_6} \) and then setting \( A = 0 \), and by using (3.15), it is apparent that the multi-point dimer correlations can be all computed explicitly in terms of a suitable fermionic Wick rule.

For later reference, let us also set our conventions for the Fourier transform of Grassmann fields: we let

\[ \psi_k^\pm = \sum_{x \in \Lambda} e^{i k x} \psi_x^\pm, \quad k \in \mathcal{D}_\Lambda, \] (3.19)

so that

\[ \psi_x^\pm = \frac{1}{L^2} \sum_{k \in \mathcal{D}_\Lambda} e^{i k x} \psi_k^\pm. \] (3.20)
3.2. Decomposition of Dirac fields

It is convenient, for the comparison with the relativistic model of section 5, to decompose the Grassmann fields $\psi_x^\pm$ into sums of so-called Dirac fields. First of all, we let $\chi^+(\cdot)$ be a non-negative ‘cut-off function’, i.e. a smooth function on $[-\pi, \pi]^2$ satisfying the following:

- letting $\chi^-(k) = \chi^+(k - (\pi, \pi))$, one has $\chi^+(k) + \chi^-(k) = 1$;
- $\chi^+(\cdot)$ is centered at the origin, is even in $k$ and its support does not include $2\pi$.

As discussed in [25, appendix C], it is technically convenient to assume that $\chi^+$ is in the Gevrey class of order 2 (which, in particular, implies that it is $C^\infty$). To avoid ambiguity, one should think of $\chi^+$ as a suitably smoothed version of the indicator $1_{\{\|k\| + |k| \leq \pi\}}$.

By using the ‘addition principle’ for Grassmann integrals (see [25, proposition 1]) we rewrite the field $\psi$ as the combination of two independent Grassmann fields $\psi_\omega$, $\omega \in \{\pm\}$, via the following:

$$
\psi_x^\pm = \sum_{\omega = \pm} e^{ip^x x_\omega} \psi_{x,\omega}^\pm = \psi_{x,+,\omega}^\pm + (-1)^{x_0} \psi_{x,-,\omega}^\pm \tag{3.21}
$$

Here, and in the following, whenever $x = (x_1, x_2) \in \mathbb{Z}^2$, we let $(-1)^x := (-1)^{x_1 + x_2}$. The rewriting (3.21) should be meant as a statement that, for every function $f$ of the Grassmann field $\psi$,

$$
\mathcal{E}_{0,\lambda}(f(\psi)) = \tilde{\mathcal{E}}_{0,\lambda}(\tilde{\mathcal{E}}_0(\tilde{\mathcal{E}}_0( f(\psi_{x,+,\omega}^\pm, \psi_{x,-,\omega}^\pm, \omega \in \Lambda)), \tag{3.22}
$$

where $\tilde{f}(\{\psi_{x,+,\omega}^\pm, \psi_{x,-,\omega}^\pm, \omega \in \Lambda) = f(\{\psi_{x,+,\omega}^\pm + (-1)^{x_0} \psi_{x,-,\omega}^\pm, \omega \in \Lambda)$, and $\tilde{\mathcal{E}}_{0,\lambda}$ is the Grassmann Gaussian integration on the $\psi_\omega$ fields with propagator

$$
\tilde{\mathcal{E}}_{0,\lambda}(\psi_{x,\omega}^- \psi_{y,\omega}^+) = \frac{1}{L^2} \sum_{k \in D_\lambda} \frac{e^{-ik \cdot p}(x-y)}{\mu(k)} \chi^\omega(k) \tag{3.23}
$$

and $\tilde{\mathcal{E}}_{0,\lambda}(\psi_{x,\omega}^- \psi_{y,\omega}^+) = 0$.

**Remark 3.** Note that the effect of the cut-off function $\chi^\omega$ is to restrict the integration close to the singularity $p^\omega$. Therefore, at large distances, one has

$$
\tilde{\mathcal{E}}_{0,\lambda}(\psi_{x,\omega}^- \psi_{y,\omega}^+) \approx \frac{1}{L^2} \sum_{k \in D_\lambda} \frac{e^{-ik \cdot p}(x-y)}{D_\omega(k)} \chi^+(k) \approx \frac{1}{2\pi(1-i\omega)(x_1 - y_1) + (1+i\omega)(x_2 - y_2)} \frac{1}{2\pi(1-i\omega)(x_1 - y_1) + i\omega(x_2 - y_2)}, \tag{3.24}
$$

with $D_\omega(k)$ defined in (3.9). This will be used in the comparison between the dimer model and the continuum fermionic model of section 5.
3.3. Interacting model

As discussed in [25, sections 2.3 and 2.4], equation (3.17) admits the following natural generalization to the interacting case:

$$\lim_{m \to 0} \lim_{L \to \infty} \mathcal{W}_\Lambda(A) = \lim_{L \to \infty} W_\Lambda(A),$$

(3.25)

where

$$W_\Lambda(A) = \log \frac{\int[\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-]e^{V(\psi, A)}}{\int[\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-]e^{V(\psi, 0)}}$$

(3.26)

and

$$V(\psi, A) = \sum_\gamma (-1)^{||\gamma||} \alpha^{||\gamma||} - 1 \prod_{e \in \gamma} E_e A_e.$$  

(3.27)

Here, $\alpha = \exp(\lambda) - 1$, $\gamma$ are collections of parallel bonds in $\mathbb{T}_L$ belonging to the same horizontal or vertical strip: $\gamma = (e_1, \ldots, e_k)$, with $k \geq 1$. In section 4, in order to derive the lattice Ward identities, we will generalize $W_\Lambda(A)$ to a generating function $W_\Lambda(A, \phi)$, with $\phi$ being a ‘Grassmann external source’, with respect to which we will take derivatives.

Note that, at zero external source, and at lowest non-trivial order in $\lambda$, the Grassmann action takes the form

$$V(\psi, 0) = -(\psi^+, K_0 \psi^-) + \lambda V_d(\psi) + O(\lambda^2),$$

where

$$V_d(\psi) = -2 \sum_{x \in \Lambda} \left[ \psi_x^+ \psi_{x+[0,1]} \psi_{x-[1,0]} + \psi_x^+ \psi_{x+[1,0]} \psi_{x-[0,1]} \right].$$

(3.28)

For later reference, we introduce the symbol $\mathcal{E}_{\Lambda, A}(-\cdot)$ for the ‘interacting measure’

$$\mathcal{E}_{\Lambda, A}(f(\psi)) = \frac{\int[\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-]e^{\psi(0) f(\psi)}}{\int[\prod_{x \in \Lambda} d\psi_x^+ d\psi_x^-]e^{V(\psi, 0)}}$$

(3.29)

and we let $\mathcal{E}_\Lambda$ be the weak limit of $\mathcal{E}_{\Lambda, A}$ as $L \to \infty$.

We also define

$$\mathcal{I}_e = \sum_{\gamma: \gamma \ni e} (-1)^{||\gamma||} \alpha^{||\gamma||} - 1 \prod_{e' \in \gamma} E_{e'},$$

(3.30)

which is the fermionic counterpart of the dimer operator $1_e$, in the sense that for instance

$$\lim_{m \to 0} \lim_{L \to \infty} \langle 1_e \rangle_{\Lambda, A, m} = \mathcal{E}_\Lambda(\mathcal{I}_e),$$

(3.31)

and

$$\lim_{m \to 0} \lim_{L \to \infty} \langle 1_e 1_{e'} \rangle_{\Lambda, A, m} = \mathcal{E}_\Lambda(\mathcal{I}_e \mathcal{I}_{e'}),$$

(3.32)

provided $e, e'$ have different orientations, or they have the same orientation, but there is no $\gamma$ made of parallel adjacent bonds that contain both. In order to prove (3.31) and (3.32), it is enough to differentiate (3.25) with respect to $A_e$ and $(A_{e}, A_{e'})$, and then set

https://doi.org/10.1088/1742-5468/aa5d1f
$A \equiv 0$ (the possibility of exchanging the limits $\lim_{m \to 0} \lim_{L \to \infty}$ with the derivatives with respect to $A$ follows from the uniform bounds on the generating function proved in [25]).

**Remark 4.** For future reference, it is useful to re-express the Grassmann action, $V(\psi, 0)$, and the Grassmann counterpart of the dimer observable, $I_e$, in terms of Dirac fields: for this purpose, it is enough to plug (3.21) into the definition of $E_e$, and then use (3.27) and (3.30). If we denote by $E'_e$, $e \in \{1, 2, 3, 4\}$, the operator $E_e$ with $e$ the edge of type $r$ with black vertex at $x$, we find:

$$E'_e = K_r \left[ \sum_{\omega} \omega^{r-1} \psi^+_{x,\omega} \psi^-_{x+v,\omega} + (-1)^{x} \sum_{\omega} (-\omega)^{r-1} \psi^+_{x,\omega} \psi^-_{x+v,\omega} \right]$$

(3.33)

where $v_1 = 0, v_2 = -(1, 0), v_3 = -(1, 1), v_4 = -(0, 1)$. Using this expression, we see that the quadratic part of the action, $-(\psi^+, K_0 \psi^-)$, reads

$$-(\psi^+, K_0 \psi^-) = \sum_{x, r, \omega} K_r^\omega \omega^{r-1} [\psi^+_{x,\omega} \psi^-_{x+v,\omega} + (-1)^{x} \omega^{r-1} \psi^+_{x,\omega} \psi^-_{x+v,\omega}] ,$$

(3.34)

while the ‘interaction’ $V_{\text{int}}(\psi) := V(\psi, 0) + (\psi^+, K_0 \psi^-)$ can be re-expressed, at dominant order, as

$$V_{\text{int}}(\psi) = -16\alpha \sum_x \psi^+_{x,+} \psi^-_{x,+} \psi^+_{x,-} \psi^-_{x,-} + \text{h.o.},$$

(3.35)

Here ‘h.o.’ denotes higher-order terms, namely ‘non-local quartic terms’, or terms of order 6 or higher in the Grassmann fields. All these higher-order terms are ‘irrelevant’ in the RG sense (see [25, sections 5 and 6]).

Similarly, if $e$ is the edge of type $r$ with black vertex at $e$, the operator $I_e$ can be rewritten as

$$I_e = -K_r \left[ \sum_{\omega} \omega^{r-1} \psi^+_{x,\omega} \psi^-_{x,\omega} + (-1)^{x} \sum_{\omega} (-\omega)^{r-1} \psi^+_{x,\omega} \psi^-_{x,\omega} \right] + \text{h.o.},$$

(3.36)

where the higher-order terms are either non-local quadratic terms, or terms of the fourth order or higher in the Grassmann fields.

### 4. Ward identities

A crucial role in the proof of theorem 1 is played by lattice conservation laws, which induce exact relations (Ward identities) among the correlation functions. The basic microscopic conservation law inducing the Ward identities is the fact that the number of dimers incident to a given vertex of $V_B/V_W$ is identically equal to 1.

---

9 These are the terms quartic in the Grassmann fields, where one or more fields are replaced by their discrete derivatives: they result from rewriting $\psi^-_{x+v,\omega} = \psi^-_{x,\omega} + (\nabla_v \psi^-)_{x,\omega}$ in (3.33), where $\nabla_v$ is, by definition, the discrete derivative in direction $v_v$. 

https://doi.org/10.1088/1742-5468/aa5d1f
In order to derive these identities, we need to generalize the generating function (3.26), since the identities will involve correlation functions that cannot be obtained as derivatives of \( W_\Lambda(A) \) with respect to the variables \( A_e \). That is to say, given a set of Grassmann variables \( \{ \phi^+_x, \phi^-_x \} \in \Lambda \) and (as before) a set of real numbers \( A_e \) associated to edges \( e \), we define

\[
W_\Lambda(A, \phi) = \log \frac{\int [\prod_{x \in \Lambda} d\psi^+_x d\psi^-_x] e^{\psi^+_x A_e + \phi^-_x A_e}}{\int [\prod_{x \in \Lambda} d\psi^+_x d\psi^-_x] e^{\psi^+_x 0 + \phi^-_x 0}}.
\]

(4.1)

Here, \( (\psi^+, \phi^-) := \sum_{x \in \Lambda} \psi^+_x \phi^-_x \), and this is similar for \( (\phi^+, \psi^-) \).

**Remark 5.** As any function of a finite number of Grassmann variables, the function \( W_\Lambda(A, \phi) \) is a polynomial in \( \{ \phi^+_x, \phi^-_x \} \in \Lambda \). If \( W_\Lambda(A, 0) \) is the monomial that contains none of the \( \phi \) variables, then we have

\[
W_\Lambda(A, 0) = W_\Lambda(A),
\]

(4.2)

with \( W_\Lambda(A) \) defined in (3.26).

We will also need to take derivatives of \( W_\Lambda(A, \phi) \) w.r.t. \( \phi^\pm_x \). By this we simply mean the following: if the sum of monomials of \( W_\Lambda(A, \phi) \) that contains \( \phi^\pm_x \) is written as \( f(\phi) \) (with \( f \) a polynomial not containing \( \phi^\pm_x \) then \( \partial_{\phi^\pm_x} W_\Lambda(A, \phi) := f(\phi) \). Note that \( \partial_{\phi^+_x} \) and \( \partial_{\phi^-_x} \) anti-commute.

The following identities hold:

**Proposition 1.** For every \( x, y, z \in \Lambda \) we have

\[
\sum_{e \in b(e) = x} \partial_{A_e} \partial_{\phi^+_x} \partial_{\phi^+_y} W_\Lambda(0, 0) + \delta_{x = z} \partial_{\phi^{+}_y} \partial_{\phi^{+}_z} W_\Lambda(0, 0) = 0
\]

(4.3)

\[
\sum_{e \in u(e) = x} \partial_{A_e} \partial_{\phi^+_x} \partial_{\phi^+_y} W_\Lambda(0, 0) + \delta_{x = y} \partial_{\phi^{+}_y} \partial_{\phi^{+}_z} W_\Lambda(0, 0) = 0.
\]

(4.4)

**Proof.** The starting point in the derivation of (4.3) is a ‘local gauge covariance property’ of the Grassmann generating function \( W_\Lambda(A, \phi) \), i.e. an identity satisfied by \( W_\Lambda(A, \phi) \) when the Grassmann variables \( \psi^e_x \) are multiplied by a phase depending on \( x \) and \( \sigma \).

Grassmann integrals are known to satisfy the following: if \( \psi_1, \ldots, \psi_n \) are Grassmann variables and \( \psi(\psi) = \sum_{j \leq n} a_j \psi_j \) are linear combinations of the \( \psi \) variables, then

\[
\int \prod_j d\psi_j f(\psi) = (\det a)^{-1} \int \prod_j d\psi_j f(\psi).
\]

(4.5)

In our case, consider the phase transformation \( \psi^{\pm}_x \rightarrow \tilde{\psi}^{\pm}_x = e^{i\alpha^\pm_x} \psi^{\pm}_x \), with \( \alpha^\pm_x \in \mathbb{R} \). Note that the combination \( E_e e^{A_e} \) appearing in the definition of \( V(\psi, A) \) (see (3.27)) transforms as follows under the phase transformation: \( E_e e^{A_e} \rightarrow E_e e^{i\alpha_e + A_e} \), where \( \alpha_e = \alpha_{b(e)} + \alpha_{u(e)} \). Therefore equation (4.5), together with the fact that in our case
Haldane relation for interacting dimers

\[
\det a = e^{i \sum_{x \in \Lambda} (\alpha^+_x + \alpha^-_x)},
\]

implying

\[
W_A(A, \phi) = -i \sum_{x \in \Lambda} (\alpha^+_x + \alpha^-_x) + W_A(A + i\alpha, \phi e^{i\alpha})
\]

(4.6)

with \((\phi e^{i\alpha})^\sigma_x = \phi^\sigma_x e^{i\alpha x^\sigma}, \sigma = \pm\). By repeatedly deriving this identity with respect to \(A\) and \(\phi\), and then setting \(A = \phi = 0\), we obtain a sequence of exact identities among the correlation functions, known as Ward identities.

We are particularly interested in (4.3), relating the ‘vertex function’, \(\partial_A \partial_{\phi^+} \partial_{\phi^-} W_A(0, 0)\) with the ‘dressed propagator’ \(\partial_{\phi^+} \partial_{\phi^-} W_A(0, 0)\). In order to get this, we start by deriving (4.6) once with respect to \(\alpha^+_x\) and then set \(0^+_x = 0\), thus obtaining

\[
\sum_{e : b(e) = x} \partial_A W_A(A, \phi) + \phi^-_x \partial_{\phi^-} W_A(A, \phi) = 1.
\]

(4.7)

Similarly, deriving with respect to \(\alpha^-_x\) and setting \(0^-_x = 0\), we obtain

\[
\sum_{e : w(e) = x} \partial_A W_A(A, \phi) + \phi^+_x \partial_{\phi^+} W_A(A, \phi) = 1.
\]

(4.8)

Next, we derive (4.7) and (4.8) w.r.t. \(\phi^+_y\) and \(\phi^-_z\) and we set \(\phi = A = 0\), thereby finding (4.3).

\[
\text{Equations (4.3) can be rewritten as}
\]

\[
\sum_{e : b(e) = x} \mathcal{E}_{\lambda, \Lambda}(\mathcal{I}_e; \psi^-_y \psi^+_z) + \delta_{x-y} \mathcal{E}_{\lambda, \Lambda}(\psi^-_y \psi^+_x) = 0
\]

(4.9)

\[
\sum_{e : w(e) = x} \mathcal{E}_{\lambda, \Lambda}(\mathcal{I}_e; \psi^-_y \psi^+_z) + \delta_{x-y} \mathcal{E}_{\lambda, \Lambda}(\psi^-_x \psi^+_z) = 0,
\]

(4.10)

where the semicolon indicates truncated expectation (i.e. \(\mathcal{E}_{\lambda, \Lambda}(A; B) = \mathcal{E}_{\lambda, \Lambda}(AB) - \mathcal{E}_{\lambda, \Lambda}(A) \mathcal{E}_{\lambda, \Lambda}(B)\)).

**Remark 6.** If \(\lambda = 0\), one can check that (4.9) reduces to the statement that \(\mathcal{E}_{0, \Lambda}(\psi^-_y \psi^+_y) = K_0^{-1}(x, y)\) satisfies \(K_0 K_0^{-1} = I\), i.e. the non-homogeneous discrete Cauchy–Riemann equation.

If \(e\) is the edge of type \(r \in \{1, 2, 3, 4\}\) with \(b(e) = x\), we let

\[
G^{(2, 1)}_r(x, y, z) := \mathcal{E}_{\lambda}(\mathcal{I}_r; \psi^-_x \psi^+_z)
\]

(4.11)

(recall that \(\mathcal{E}_{\lambda}\) is the \(L \to \infty\) limit of \(\mathcal{E}_{\lambda, \Lambda}\)). Similarly, we define

\[
G^{(2)}(x, y) := \mathcal{E}_{\lambda}(\psi^-_x \psi^+_y).
\]

(4.12)

Note that both \(G^{(2, 1)}_r\) and \(G^{(2)}\) are translationally invariant. Their Fourier transform is defined by

\[https://doi.org/10.1088/1742-5468/aa5d1f\]
Haldane relation for interacting dimers

\[ \hat{G}^{(2)}(p) = \sum_x G^{(2)}(x, 0)e^{ipx} \quad (4.13) \]

\[ \hat{G}^{(2,1)}_r(k, p) = \sum_{x,z} e^{-ipx-ikz} G^{(2,1)}_r(x, 0, z) \quad (4.14) \]

so that

\[ \int_{[-\pi, \pi]^2} \frac{dp}{(2\pi)^2} e^{-ipx} \hat{G}^{(2)}(p) = G^{(2)}(x, 0) \quad (4.15) \]

\[ \int_{[-\pi, \pi]^2} \frac{dp}{(2\pi)^2} \int_{[-\pi, \pi]^2} \frac{dk}{(2\pi)^2} e^{ipx+ikz} \hat{G}^{(2,1)}_r(k, p) = G^{(2,1)}_r(x, 0, z). \quad (4.16) \]

From (4.9)–(4.10) we finally deduce our exact lattice Ward identity of interest:

**Proposition 2 (Lattice Ward identities).** For every \( x, y, z, \)

\[ \delta_{x=y} G^{(2)}(x, z) - \delta_{x=z} G^{(2)}(y, x) = - \sum_{r=2}^4 \nabla_{\nu_r} G^{(2,1)}_r(x, y, z), \quad (4.17) \]

where \((\nabla_x f)(x, y, z) := f(x + n, y, z) - f(x, y, z)\) is the (un-normalized) discrete derivative acting on the \( x \) variable.

After Fourier transform, this identity reads

\[ \hat{G}^{(2)}(k + p) - \hat{G}^{(2)}(k) = \sum_{r=2}^4 (e^{-ip\nu_r} - 1) \hat{G}^{(2,1)}_r(k, p). \quad (4.18) \]

5. The reference model

In order to prove theorem 1, we intend to follow a logic analogous to [9, 10]. The general scheme is as follows: we introduce a relativistic reference model whose correlation functions have the same long-distance behavior as our lattice model, provided the bare parameters entering the definition of its action are properly chosen. The relativistic model satisfies Ward identities corresponding to local chiral-gauge invariance, which guarantees the validity of exact scaling relations among the critical exponents of its correlation functions (and, therefore, \textit{a posteriori}, of the correlation functions of the dimer model). In addition to the relations between critical exponents, we can get exact relations among the exponents and the amplitudes of the correlations, by comparing the relativistic Ward identities with the lattice ones, which are the same at dominant order (asymptotically at large distances, or for momenta close to the Fermi points).

In this section, we introduce the reference relativistic model and recall its Ward identities. The reference model is nothing but the formal scaling limit of the Grassmann integral of our dimer model, properly regularized, thanks to the presence of: (1) a smooth non-local density–density potential \( \nu_0 \), decaying on a fixed scale, which sets the unit length (the smooth, rather than delta-like, potential provides an ultraviolet cut-off
on the fermionic interaction), (2) an infrared regularization on the propagator, induced by the presence of a finite box of side \(L\) and by the anti-periodic boundary conditions enforced on the Grassmann fields, (3) an ultraviolet regularization on the propagator, which cuts off the momenta larger than \(2N\), with \(N \gg 1\), and (4) an underlying lattice of mesh \(a\), which guarantees that the number of Grassmann variables is finite. The limit \(a \to 0\), followed by \(N \to \infty\) and then \(L \to \infty\), is called the ‘limit of removed cut-offs’. Note that in this limit the decay scale of \(\nu_0\) is kept fixed; therefore, even the limiting theory has an ultraviolet regularization, which guarantees the finiteness of the bare parameters to be fixed.

Given \(L > 0\) and an integer \(M\), we let \(a = L/M\) and we define \(\Lambda = a \mathbb{Z}^2 / L \mathbb{Z}^2\) to be the discrete torus of side \(L\) and lattice mesh \(a\). The reference model is defined in terms of a generating functional \(W_\Lambda^0(J, \phi)\) parametrized by

- four real constants \(Z, Z^{(1)}, Z^{(2)}, \lambda_\infty\);
- external sources \(J\), where \(J = \{J^{(j)}\}_{\omega = \pm, x \in \Lambda}\) and \(J^{(j)}_{x, \omega}\) \(\in \mathbb{R}\);
- external Grassmann sources \(\phi\), where \(\phi = \{\phi^\sigma_{x, \omega}\}_{x \in \Lambda}\) and \(\phi^\sigma_{x, \omega}\) is a Grassmann variable.

The generating function is defined by

\[
e^{W_\Lambda^0(J, \phi)} = \frac{\int P^\Lambda_{\xi N}(d\psi)e^{i(\sqrt{Z}\psi) + \sum_{j=1}^{2} Z^{(j)}(J^{(j)} + \rho^{(j)}) + Z[\psi^+, \phi^+ + (\phi^+, \psi^-) + (\phi^-, \psi^-)]}}{\int P^\Lambda_{\xi N}(d\psi)e^{i(\sqrt{Z}\psi)}},
\]

(5.1)

where, letting \(\int_\Lambda dx := a^2 \sum_{x \in \Lambda}\), we define \((J^{(j)}, \rho^{(j)}) := \sum_{\omega} \int_\Lambda dx J^{(j)}_{x, \omega} \rho^{(j)}_{x, \omega}\), with

\[
\rho^{(1)}_{x, \omega} = \psi^+_{x, \omega} \psi^-_{x, \omega}, \quad \rho^{(2)}_{x, \omega} = \psi^+_{x, \omega} \psi^-_{x, -\omega}.
\]

(5.2)

Moreover, \(P^\Lambda_{\xi N}(d\psi)\) is the fermionic measure with propagator (satisfying anti-periodic boundary conditions over \(\Lambda\))

\[
\frac{1}{Z^2} g_{R, \omega}(x - y) = \frac{1}{2} \sum_{k \in D} e^{-ik(x-y)} \frac{\chi_N(k)}{(-i - \omega)k_1 + (-i + \omega)k_2},
\]

(5.3)

where \(\chi_N(k) = \chi(2^{-N}|k|)\), with \(\chi : \mathbb{R}^+ \to \mathbb{R}\) a \(C^\infty\) cutoff function that is equal to 1, if its argument is smaller than 1; and equal to 0, if its argument is larger than 2, and \(D = (2\pi/L)(\mathbb{Z}/M \mathbb{Z} + 1/2)^2\) (we recall that \(M = L/a\)).

**Remark 7.** Note that, in the limit of removed cut-offs, the cut-off function \(\chi_N\) tends to 1, the Riemann sum over \(k \in D\) tends to the corresponding integral, so that (5.3) reduces to \(1/Z\) times the inverse of the Dirac operator

\[
D^x_\omega := (1 - i\omega)\partial_{x_1} + (1 + i\omega)\partial_{x_2}.
\]

(5.4)
Additionally, compare (5.3) with (3.24): asymptotically at large distances, the lattice Grassmann fields $\psi_{x,\omega}^\pm$ and the those of the continuous model have the same propagator (apart from the constant pre-factor $1/Z$).

Finally, the interaction is

$$\mathcal{V}(\psi) = \frac{\lambda_\infty}{2} \sum_{\omega = \pm} \int_\Lambda dx \int_\Lambda dy \, v_0(x - y) \psi_{x,\omega}^+ \psi_{x,\omega}^- \psi_{y,\omega}^- \psi_{y,\omega}^+,$$

where $v_0$ is a smooth rotationally invariant potential, exponentially decaying to zero at large distances, of the form

$$v_0(x) = \frac{1}{L^2} \sum_{p \in (2\pi/L)^2} \hat{v}_0(p)e^{ipx},$$

with $|\hat{v}_0(p)| \leq Ce^{-|p|}$ for some constants $C$, $c$, and $\hat{v}_0(0) = 1$. Note the similarity between (5.5) and the dominant, ‘local’, quartic interaction of the interacting dimer model, (3.35).

We shall use the following definitions\(^\text{10}\):

$$G_{R,\omega,\omega'}^{(2,1)}(x, y, z) = \lim_{L \to \infty} \lim_{a \to 0} \frac{\partial^3}{\partial J_{x,\omega}^{(1)} \partial \phi_{y,\omega}^- \partial \phi_{y,\omega}^+} \mathcal{W}_N(J, \phi)|_{J = \phi = 0},$$

$$G_{R,\omega,\omega}^{(2)}(x, y) = \lim_{L \to \infty} \lim_{a \to 0} \frac{\partial^2}{\partial \phi_{y,\omega}^- \partial \phi_{x,\omega}^+} \mathcal{W}_N(J, \phi)|_{J = \phi = 0},$$

$$S_{R,\omega,\omega}^{(j,j)}(x, y) = \lim_{L \to \infty} \lim_{a \to 0} \frac{\partial^2}{\partial J_{x,\omega}^{(1)} \partial J_{y,\omega}^{(1)}} \mathcal{W}_N(J, \phi)|_{J = \phi = 0}. \tag{5.7}$$

The very existence of the limits on the right-hand side follows from the construction of the correlation functions of the reference model, performed, e.g. in [6, sections 3 and 4]. The Fourier transforms of the correlations in (5.7) are defined as follows:

$$G_{R,\omega,\omega'}^{(2,1)}(x, y, z) = \int_{\mathbb{R}^3} \frac{dk}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} e^{ipx - i(k+p)y + ikz} G_{R,\omega,\omega'}^{(2,1)}(k, p),$$

$$G_{R,\omega,\omega}^{(2)}(x, y) = \int_{\mathbb{R}^2} \frac{dk}{(2\pi)^2} e^{-ik(x-y)} G_{R,\omega,\omega}^{(2)}(k),$$

$$S_{R,\omega,\omega}^{(j,j)}(x, y) = \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} e^{ip(y-x)} S_{R,\omega,\omega}^{(j,j)}(p). \tag{5.8}$$

In the limit of removed cut-offs, $\hat{G}_{R,\omega,\omega}^{(2,1)}$ and $\hat{G}_{R,\omega,\omega}^{(2)}$ satisfy the following remarkable identities: for small $\lambda_\infty$, if $k$ and $k + p$ are different from 0,

$$\frac{Z}{Z^{(1)}} \sum_{\omega' = \pm} D_{\omega}(p) G_{R,\omega',\omega}^{(2,1)}(k, p) = \hat{F}(p)[\hat{G}_{R,\omega}^{(2)}(k) - \hat{G}_{R,\omega}^{(2)}(k + p)], \tag{5.9}$$

\(^{10}\) On the right-hand side of (5.7), the space label $x, y, z$ of the external fields $J_{x,\omega}^{(1)}, \phi_{x,\omega}^\pm$ should actually be interpreted as the points $x_0, y_0, z_0$ in $\Lambda$ closest to $x, y, z$. Clearly, $\lim_{a \to 0} x_a = x$, etc. In the formulas, we drop the label a purely for lightness of notation.
where \( D_p(p) \) was defined in (3.10), and

\[
\hat{F}(p) = \frac{1}{1 - \tau \hat{v}_0(p)}, \quad \tau = \frac{\lambda_{\infty}}{8\pi},
\]  

(5.10)

The equation (5.9) is a Ward identity, derived by a local chiral-gauge transformation of the Grassmann field \( \psi \), i.e. by the \( \omega \)-dependent phase transformation \( \psi_{x,\omega}^\pm \to e^{i\pi \omega(x)} \psi_{x,\omega}^\pm \). The fact that \( \hat{F}(p) \) is not equal to 1 is a manifestation of the ‘anomalies’ in quantum field theory. Finally, the linearity of \( 1/\hat{F}(p) \) in terms of \( \lambda_{\infty} \) is a property called ‘anomaly non-renormalization’. Equation (5.9) was proved in [47]; see also [6] and the comments after proposition 12 in [25]. A sketch of its proof is also discussed, for completeness, in appendix C.

Similarly, the density–density correlations \( S^{(1,1)}_{R,\omega,\omega}(x, y) \) satisfy the following identities (see, again, appendix C):

\[
D_\omega(p)S^{(1,1)}_{R,\omega,\omega}(p) - \tau \hat{v}_0(p)D_\omega(p)S^{(1,1)}_{R,-\omega,\omega}(p) + \frac{(Z^{(1)})^2}{8\pi Z^2} D_\omega(p) = 0,
\]

\[
D_\omega(p)S^{(1,1)}_{R,-\omega,\omega}(p) - \tau \hat{v}_0(p)D_\omega(p)S^{(1,1)}_{R,\omega,\omega}(p) = 0,
\]

(5.11)

which imply:

\[
\hat{S}^{(1,1)}_{R,\omega,\omega}(p) = -\frac{1}{Z^2} \frac{(Z^{(1)})^2}{8\pi(1 - \tau^2 \hat{v}_0(p)^2)} D_\omega(p),
\]

(5.12)

6. Proof of Theorem 1

In order to transfer the information encoded in the Ward identities of the reference model to the correlation functions of the dimer model, we choose the parameters \( Z, Z^{(1)}, Z^{(2)}, \lambda_{\infty} \) of the reference model so that its correlations are asymptotically the same as those associated with the lattice’s Grassmann generating function (3.26), in the limit of small momenta/large distances. More precisely, the parameters of the reference model can be fixed so that the following asymptotic relation among the correlation functions of the two models is valid.

**Lemma 1.** Given \( \lambda \) small enough, there are constants \( Z, Z^{(1)}, Z^{(2)}, \lambda_{\infty} \), depending analytically on \( \lambda \), such that, if \( \lvert p \rvert \ll 1 \),

\[
\hat{G}_{r,r'}^{(0,2)}(p) = K_rK_{r'} \sum_{\omega=\pm} \omega^{r'+r'} \hat{S}^{(1,1)}_{R,\omega,\omega}(p) + R_{r,r'}(p),
\]

(6.1)

\[
\hat{G}_{r,r'}^{(0,2)}(p^{-} + p) = K_rK_{r'} \sum_{\omega=\pm} (-1)^{r'-1} \omega^{r'+r'} \hat{S}^{(2,2)}_{R,\omega,-\omega}(p) + R'_{r,r'}(p),
\]

(6.2)

where \( R_{r,r'}(p) \) and \( R'_{r,r'}(p) \) are continuous in \( p \), notably at \( p = 0 \). Moreover, supposing

https://doi.org/10.1088/1742-5468/aa5d1f

26
Haldane relation for interacting dimers

that \(0 < \epsilon \leq |p|, |k|, |k + p| \leq 2\epsilon\) for some \(\epsilon < 1\), then for any \(0 < \theta < 1\) one has

\[
\hat{G}_r^{(2)}(k + p^\sigma; p) = -K_r \sum_{\omega' = \pm} (\omega')^{-1} \hat{G}^{(2)}_{R_{\omega',\omega}}(k, p)[1 + O(\epsilon^0)], \tag{6.3}
\]

\[
\hat{G}_r^{(2)}(k + p^\sigma) = \hat{G}^{(2)}_{R_{\omega}}(k)[1 + O(\epsilon^0)]. \tag{6.4}
\]

**Remark 8.** At lowest non-trivial order in \(\lambda\), the parameters of the reference model are: \(Z = 1 + O(\lambda), Z^{(1)} = 1 + O(\lambda), Z^{(2)} = 1 + O(\lambda),\) and \(\lambda_\infty = -16\lambda + O(\lambda^2)\). In order to obtain these values, at lowest non-trivial order, it is enough to fix the parameters in the bare Grassmann actions of the reference and dimer models, so that the corresponding expressions match at dominant order: compare, e.g. (5.3) with (3.24) and (5.5) with (3.35).

Lemma 1 is a restatement (using new notations) and a slight extension of [25, proposition 12]. The comparison between Lemma 1 and [25, proposition 12] is discussed in the next section. Let us now discuss its implications; in particular, let us show how to use it in order to prove theorem 1.

By combining (6.3) and (6.4) with (4.18), and using the fact that \(\sum_{r=2}^{4} K_r (p \cdot \nu_r)(\omega')^{-1} = -D_{\omega}(p)\), we obtain

\[
\sum_{\omega' = \pm} D_{\omega}(p) \hat{G}^{(2)}_{R_{\omega',\omega}}(k, p) = [\hat{G}^{(2)}_{R_{\omega}}(k) - \hat{G}^{(2)}_{R_{\omega}}(k + p)][1 + O(\epsilon^0)], \tag{6.5}
\]

which, if compared with (5.9) and recalling that \(\delta_0(p) = 1 + O(p)\), gives

\[
\frac{Z^{(1)}}{(1 - \tau)Z} = 1. \tag{6.6}
\]

Moreover, by combining (5.12) with (6.1) we obtain:

\[
\hat{G}^{(0, 2)}_{r, \nu}(p) = -\frac{K_r K_{\nu}(Z^{(1)})^2}{8\pi Z^2(1 - \tau^2)} \sum_{\omega = \pm} \omega^{r + \nu'} D_{\omega}(p) \frac{D_{\omega'}(p)}{D_{\omega}(p)} + \hat{R}_{r, \nu}(p), \tag{6.7}
\]

where \(\hat{R}_{r, \nu}\) is continuous in \(p\), in particular, at \(p = 0\). By using (6.6), we can rewrite this equation as

\[
\hat{G}^{(0, 2)}_{r, \nu}(p) = -\frac{K_r K_{\nu}}{8\pi} \frac{1 - \tau}{1 + \tau} \sum_{\omega = \pm} \omega^{r + \nu'} D_{\omega}(p) \frac{D_{\omega'}(p)}{D_{\omega}(p)} + \hat{R}_{r, \nu}(p). \tag{6.8}
\]

Taking, for instance, \(r = \nu' = 1\) this implies that

\[
\hat{G}^{(0, 2)}_{1, 1}(p) = -\frac{1}{2\pi} \frac{1 - \tau}{1 + \tau} \frac{p_1 p_2}{p_1^2 + p_2^2} + \hat{R}_{1, 1}(p). \tag{6.9}
\]

This should be compared with the Fourier transform of (2.8). Indeed, recall from the definition (3.2) that

\[
G^{(0, 2)}_{1, 1}(x) = \langle 1_e, 1_{e'} \rangle_\lambda,
\]

with \(e, e'\) two horizontal edges of type 1, with black sites \(b(e), b(e')\) of coordinates \(x\) and 0, respectively, and white sites of coordinates \(w(e), w(e')\) also of coordinates \(x\) and 0. Therefore, (6.9) must also equal

https://doi.org/10.1088/1742-5468/aa5d1f
\[
\sum_{x \in \mathbb{Z}^2} e^{-ipx} \langle 1_x; 1_x \rangle_\lambda.
\]

(6.10)

In the computation of the Fourier transform for small values of \(p\), both the error term \(R_{1,1}(x)\) in (2.8) as well as the oscillating term proportional to \(B(\lambda)\) give a contribution that is continuous in \(p\) for \(p\) in the neighborhood of 0. In contrast, the term proportional to \(A(\lambda)\) has a Fourier transform that is not continuous at \(p = 0\), namely

\[
\sum_{x \in \mathbb{Z}^2} e^{-ipx} \langle 1_x; 1_x \rangle_\lambda = \frac{A(\lambda)}{2\pi^2} \sum_{x=0} e^{-ipx} \text{Re} \left[ \frac{1}{((x_1 + x_2) + i(x_2 - x_1))^2} \right] + \mathcal{R}(p)
\]

(6.11)

\[
= -\frac{A(\lambda)}{2\pi} \frac{p_1 p_2}{p_1^2 + p_2^2} + \mathcal{R}(p)
\]

(6.12)

where \(\mathcal{R}(p)\) and \(\overline{\mathcal{R}}(p)\) are continuous in \(p\), notably at \(p = 0\) (for a proof of the second identity, see, e.g. appendix A). By comparing this expression with (6.9) we get

\[
A(\lambda) = \frac{1 - \tau}{1 + \tau}.
\]

(6.13)

On the other hand, the right-hand side of this equation, \((1 - \tau)/(1 + \tau)\), coincides with the critical exponent of the correlation \(S_{R_{\omega,-\omega'}}^{(2,2)}\). In fact, it was proved in [6, section 4.2] (see, in particular, [6, equations (4.24) and (4.26)]), that

\[
S_{R_{\omega,-\omega'}}^{(2,2)}(x, y) = C \frac{\delta_{\omega,-\omega'}}{|x - y|^{2\nu}} + \overline{\mathcal{R}}_{\omega,\omega'}(x, y),
\]

(6.14)

where: (i) for some \(0 < \theta < 1/2\) and a suitable constant \(c_\theta > 0\), \(|\overline{\mathcal{R}}_{\omega,\omega'}(x, y)| \leq c_\theta |x - y|^{-3+\theta}\); (ii) \(C\) and \(\nu\) are analytic functions of \(\lambda_\infty\) and

\[
\nu = \frac{1 - \tau}{1 + \tau}.
\]

(6.15)

For completeness, we reproduce a sketch of the proof of this identity in appendix C.

By comparing (2.8) with (6.2), (6.14), we recognize that the critical exponent in (6.14) is the same as the one in the second line of (2.8). Therefore, by combining (6.13) with (6.15), we obtain the statement of theorem 1, as desired.

\[\Box\]

7. Comparison of lemma 1 with [25, proposition 12]

As discussed, Lemma 1 is essentially a restatement [25, proposition 12] in the notation of this paper. More precisely, (6.1) and (6.2) are obtained by Fourier transforming [25, equations (6.91) and (6.93)] with respect to \(x - y\) and then by using [25, equation (6.90)] (see below for more details). On the contrary, (6.3) and (6.4) are not part of [25, proposition 12]; however, their proof follows the same discussion as the one after [25, proposition 12].

https://doi.org/10.1088/1742-5468/aa5d1f
In order to help the reader to recognize that (6.1) and (6.2) are direct consequences of [25, equations (6.90), (6.91) and (6.93)], let us discuss more precisely the connection between the notations used here and in [25]. In order to avoid confusion, the parameters, fields and coordinates of the models in [25] will be referred to here by adding an extra tilde on the symbols: we use \( J^{(j)}_\omega (\tilde{x}) \) to denote its source terms, \( \tilde{v}(\tilde{x}) \) its potential, \( \tilde{\psi}_{x,\omega}^{\pm} \) its Grassmann fields, etc. The coordinates \( x \) used in this paper are related to those of [25], denoted by \( \tilde{x} \), by the formulas: 
\[
\tilde{x}(x) = (x_1 + x_2, x_2 - x_1) \quad \text{and its inverse} \quad x(\tilde{x}) = 1/2(\tilde{x}_1 - \tilde{x}_2, \tilde{x}_1 + \tilde{x}_2).
\]

The connection between the reference model in this paper and the one in [25, section 6.3.2] is established by fixing 
\[
J^{(j)}_{x,\omega}, v_x(\tilde{x}), \psi_\omega, \psi_\omega^+ \quad \text{and taking the same values for the parameters } Z, \lambda, \mu.
\]

By fixing the parameters in this way, the two relativistic models, in the limit of removed cut-offs, are exactly the same. The proof of this fact is straightforward; it is just a matter of tracking the normalization constants in the two cases correctly, and it is left to the reader. Note that, due to the factor \( \sqrt{2} \) in the first line of (7.1), the relativistic correlations \( S^{(j,j)}_{x,y}(x, y) \) defined in this paper are related to their analogs in [25] via the following:
\[
S^{(j,j)}_{x,y}(x, y) = 4S^{(j,j)}_{x,y}(\tilde{x}(x), \tilde{x}(y)).
\]

By using this equation and the definition of dimer–dimer correlations, we immediately get (6.1)–(6.2). In fact, by direct inspection of [25, equation (6.95)], one sees that the dimer–dimer correlation in the notations of this paper is related to the one in [25] via 
\[
G^{(0,2)}_{r,r'}(x, y) = \frac{\partial^2}{\partial \tilde{J}_{(x,r),j(r)} \partial \tilde{J}_{(0,r'),j(r')}} \tilde{S}(\tilde{J}) \bigg|_{J=0},
\]

where, given a coordinate \( x \) and \( r = 1, 2, 3, 4 \), we let \( j(r) = 1 \) if \( r = 1, 3 \) (i.e. if the edge of type \( r \) is horizontal), \( j(r) = 2 \) if \( r = 2, 4 \) (i.e. if the edge is vertical), and 
\[
\tilde{x}(x, r) = \begin{cases} 
\tilde{x}(x) & \text{if } r = 1, 2 \\
\tilde{x}(x) - (1, 0) & \text{if } r = 3 \\
\tilde{x}(x) - (0, 1) & \text{if } r = 4.
\end{cases}
\]

Moreover, by using [25, equations (6.27)–(6.28), (6.91)–(6.93), (6.96)–(6.97)], we can rewrite 
\[
G^{(0,2)}_{r,r'}(x, y) = 4K_rK_{r'} \sum_{j=1}^{2} \sum_{\omega = 1}^{\pm} [\omega^{r'+r}] S^{(1,1)}_{R,\omega,\omega}(\tilde{x}(x), \tilde{x}(y)) 
\]

\[
+ (-1)^{r'-y} \omega^{r-1}(\omega)^{r'-1} S^{(2,2)}_{R,\omega,\omega}(\tilde{x}(x), \tilde{x}(y)).
\]

By using (7.2) and [25, equation (6.90)], and by taking the Fourier transform at both sides, we finally get (6.1) and (6.2). The proof of (6.3) and (6.4) is along the same lines outlined after the statement of [25, proposition 12] and we shall not labor the point here.
Acknowledgments

We thank K Gawedzki for several enlightening discussions on the connections between the 2D massless Gaussian field and SLE processes. The main part of this work was completed during a sabbatical visit by AG to the Mathematics Department of the University Lyon 1, supported by the A*MIDEX project Hypathie (n. ANR-11-IDEX-0001-02) and funded by the ‘Investissements d’Avenir’ 25 French Government program, managed by the French National Research Agency (ANR), and by a CNRS visiting research grant, which are gratefully acknowledged. FT was partially supported by the CNRS PICS grant ‘Interfaces aléatoires discrètes et dynamiques de Glauber’ and by the ANR-15-CE40-0020-03 Grant LSD.

Appendix A. Fourier singularities of the dimer–dimer correlation

In this section, we compute the dominant behavior of the Fourier transform \( \hat{G}_{r,r'}(p) \) of the dimer–dimer correlation (2.8) close to the Fermi points, \( p = 0 \) and \( p = (\pi, \pi) \). The formulas derived here will be useful in the first-order computation of \( A(\lambda) \) and \( \nu(\lambda) \), discussed in the next appendix.

More precisely, we prove that, if \( |p| \leq 1 \),

\[
\hat{G}^{(0,2)}_{r,r'}(p) = -\frac{A(\lambda)}{4\pi} \sum_{x=0} e^{-ipx} \text{Re} \left[ \frac{e^{i\pi/2(r+r')}}{(x_1 + x_2 + i(x_2 - x_1))^2} \right] + F^+(r,r')(p),
\]

where \( \nu = \nu(\lambda) \), and \( F^\pm_{r,r'} \) are functions that are continuous in \( p \) in the neighborhood of \( p = 0 \), uniformly in \( \lambda \), for \( \lambda \) small.

A.1. Singularity at \( p = 0 \)

In order to prove the first line of (A.1), we note that the discontinuous part of \( \hat{G}^{(0,2)}_{r,r'}(p) \) at \( p = 0 \) comes from the first term on the right-hand side of (2.8), that is, if \( |p| \leq 1 \),

\[
\hat{G}^{(0,2)}_{r,r'}(p) = -\frac{A(\lambda)}{2\pi^2} \sum_{x=0} e^{-ipx} \text{Re} \left[ \frac{e^{i\pi/2(r+r')}}{(x_1 + x_2 + i(x_2 - x_1))^2} \right] + \tilde{F}^+(r,r')(p),
\]

where \( \tilde{F}^+(r,r') \) is continuous in \( p \) in the region \( |p| \leq 1 \), uniformly in \( \lambda \). One can first rewrite this, recalling (3.7)–(3.8) and the fact that \( K_r = \exp(i\pi/2(r-1)) \):

\[
-\frac{1}{2\pi^2} \text{Re} \left[ \frac{e^{i\pi/2(r+r')}}{(x_1 + x_2 + i(x_2 - x_1))^2} \right] = -K_rK_r'g(v_{p'} - x)g(x + v_r)
\]

\[
-K_rK_r'((1)^v_{r'} + (-1)^v_{r'}(-1)^{x_1 + x_2}8\pi^2|x|^2 + O(|x|^{-3}).
\]

where we also use the fact that \((-1)^v_{r'} + (-1)^v_{r'} = 1\), if \( K_rK_r' \in \mathbb{R} \), and \((-1)^v_{r'} + (-1)^v_{r'} = -1\), if \( K_rK_r' \in i\mathbb{R} \). By plugging (A.3) into (A.2), we get

https://doi.org/10.1088/1742-5468/aa5d1f
\[ G_{r,v'}^{(0,2)}(p) = -A(\lambda) K_r K_{v'} \int_{[-\pi,\pi]^2} \frac{dk}{2\pi^2} \frac{e^{-ik(\delta_{rv}+\nu_v)}}{\mu(k)\mu(k+p)} + F_{r,v}^+(p), \]  

(A.4)

where \( F_{r,v}^+ \) is continuous in \( p \) in the region \(|p| \leq 1\), uniformly in \( \lambda \).

Now, the desired result follows from the explicit computation of the integral over \( k \), which is summarized in the following proposition, formulated here in greater generality for later convenience (the first line of (A.1)), follows an application of this proposition, with \((a, b) = -\nu_r - \nu_{r'}\).

**Proposition A.3.** Let \( a, b \in \mathbb{Z} \). Let

\[ I_{a,b}(p) = \int_{[-\pi,\pi]^2} \frac{dk}{2\pi^2} \frac{e^{ik(a+ib)}}{\mu(k)\mu(k+p)}. \]  

(A.5)

Then, one has

\[ I_{a,b}(p) = \frac{1}{8\pi} \left[ \frac{D_r(p)}{D_{a+b}(p)} + (-1)^{a+b} \frac{D_{a+b}(p)}{D_r(p)} \right] + \frac{i}{8\pi} \left[ 1 - (-1)^{a+b} \right] \]
\[ + \frac{(1-b)}{2\pi} \int_0^{2\pi} dk_1 e^{ik_1} a \left( 1 + ie^{ik_1} b \right)^{-2} \frac{1}{(e^{ik_1} + i)^p} [1_{|b|\leq 0} 1_{|x|<\pi} - 1_{|b|> 1} 1_{|0|<\pi}] \]
\[ + R_{a,b}(p) \]  

(A.6)

where \( R_{a,b}(p) \) vanishes continuously for \( p \to 0 \). Moreover,

\[ I_{a,b}(-p) = (-1)^{a+b} I_{a,b}(p)^*, \quad I_{a,b}(-p) = I_{a,b}(p) + R'_{a,b}(p) \]  

(A.7)

where \( R'_{a,b}(p) \) vanishes continuously for \( p \to 0 \).

Checking (A.7) is a simple exercise. The proof of (A.6) is lengthy, but straightforward; we do not give details, only a few hints. One starts by rewriting, via the change of variables \( z_j = e^{ik_j}, j = 1,2 \),

\[ I_{a,b}(p) = \frac{1}{(2\pi)^2} \oint_{z_1} dz_1 \oint_{z_2} dz_2 \frac{z_1^a z_2^b}{\hat{\mu}(z_1, z_2) \hat{\mu}(z_1 e^{ip}, z_2 e^{ip})}, \]  

(A.8)

with \( \hat{\mu}(z_1, z_2) = 1 - z_1 z_2 + i(z_1 - z_2) \) and the integrals running over \(|z_1| = |z_2| = 1\). The denominator, as a function of \( z_2 \), is a polynomial with three distinct zeros (as long as \( p \neq 0 \)). The integral w.r.t. \( z_2 \) is performed via the residue theorem and the remaining integral over \( z_1 = e^{ik_1} \) produces (A.6). The only point that requires attention is that according to the value of \( p \), some zeros can be inside or outside the integration curve \(|z_2| = 1\).

**A.2. Singularity at \( p = (\pi, \pi) \)**

Let us now prove the second line of (A.1). From (2.8) we see that

\[ G_{r,v'}^{(0,2)}((\pi, \pi) + p) = t_{r,v'} \frac{B(\lambda)}{4\pi^2} \sum_{x=0} B_\nu^x \frac{e^{-i\nu_\pi}}{|x_\nu|^2} + F_{r,v}^-(p) \]  

(A.9)

https://doi.org/10.1088/1742-5468/aa5d1f
where $\tilde{F}_{r,r'}$ is continuous in $p$ in the region $|p| \leq 1$, uniformly in $\lambda$. We have
\begin{equation}
\sum_{x=0} e^{-ip|x|} = \int_{|x| \geq 1} e^{-ipx}dx + B_1(p) \label{A10}
= 2\pi |p|^{2(\nu-1)} \int_{|p|} J_0(\rho) \rho^{2(\nu-1)}d\rho + B_1(p)
\end{equation}
where $J_0$ is the Bessel function with index $n=0$ and $B_1(p)$ is continuous in the neighborhood of $p=0$, uniformly in $\nu$, for $\nu - 1$ small. Now, by integration by parts, and recalling that $J_0(\rho) = -\rho J_1(\rho)$ and $J_0(0) = 1$, we find
\begin{equation}
\int_{|p|} J_1(\rho) \rho^{2(\nu-1)}d\rho = \frac{1}{2(\nu-1)} \left[ J_0(|p|) |p|^{2(\nu-1)} - \int_{|p|} J_1(\rho) \rho^{2(\nu-1)} \right]
= \frac{1}{2(\nu-1)} \left[ |p|^{2(\nu-1)} - \int_{0}^{\infty} J_1(\rho) \rho^{2(\nu-1)} \right] + \int_{0}^{p} J_0(\rho) \int_{0}^{p} \frac{d\rho J_1(\rho)}{x^{1-2\nu}}.
\end{equation}
Recalling that $J_1(x)$ vanishes linearly at $x=0$, we find that the last term is of order $O(|p|^{1-2\nu})$, as $p \to 0$, uniformly in $\nu$ for $\nu - 1$ small. Moreover, the integral $\int_{0}^{\infty} J_1(\rho) \rho^{2(\nu-1)}$ is explicitly known (see [27, formula 6.56114]):
\begin{equation}
\int_{0}^{\infty} J_1(\rho) \rho^{2(\nu-1)} = 2^{2(\nu-1)} \frac{\Gamma(2-\nu)}{\Gamma(\nu)}. \label{A12}
\end{equation}
By plugging this formula into (A.9)–(A.10) we obtain, the second line of (A.1) as desired.

Appendix B. First-order calculation

Here, we check that $A(\lambda) = \nu(\lambda)$ at first order in $\lambda$ and, more precisely, that (2.11) holds. From (3.2) and (3.25)–(3.27) we have it that, at first order in $\lambda$, if $e$ and $e'$ are two edges such that $r(e) = r, \ b(e) = x$, and $r(e') = r', \ b(e') = y,$
\begin{equation}
G^{(0,2)}(x,y) = \mathcal{E}_0(E_e; E_{e'}) - \lambda \mathcal{E}_0(T_e^{(1)}; E_{e'}) - \lambda \mathcal{E}_0(E_{e}; T_e^{(1)})
+ \lambda \mathcal{E}_0(E_{e}; E_{e'}; V_1) + O(\lambda^2) \label{B1}
\end{equation}
where $\mathcal{E}_0$ is the Gaussian Grassmann integration with propagator (3.11), in the limit $L \to \infty$, and the semicolon indicates truncated expectation. Moreover, given an edge $e_0$, we define $T_e^{(1)} := E_{e_0}(E_{e_1} + E_{e_2}),$ with $e_1, e_2$ the two edges parallel to $e_0$ and at a distance 1 from it, while $V_1$ was defined in (3.28). By computing all the contributions to (B.1) and by taking the Fourier transform, we obtain (see below for the details of the computation):
\[ \mathcal{G}_{r,r'}^{(0,2)}(p) = -(1 - 2\lambda)K_rK_r' \int \frac{dk}{(2\pi)^2} \frac{e^{-ik_p - i(k+p)v_r}}{\mu(k)\mu(k+p)} - 2\lambda K_rK_r' \int \frac{dk}{(2\pi)^2} \int \frac{dk'}{(2\pi)^2} \frac{W(k, k', p)e^{-iv_r(k' - p) - iv_r(k+p)}}{\mu(k)\mu(k+p)\mu(k')\mu(k' - p)} + \lambda \int \frac{dk}{(2\pi)^2} \frac{K_r e^{-iv_r(k+p)}f_r(k, p) + K_r e^{-iv_r(k+p)}f_r(k, p)}{\mu(k)\mu(k+p)} + O(\lambda^2), \] (B.2)

where the integrals over \( k \) and \( k' \) are taken over the Brillouin zone \([-\pi, \pi]^2\), and we recall that \( v_1 = (0,0), v_2 = -(1,0), v_3 = -(1,1), v_4 = -(0,1) \), while \( \mu(k) \) was defined in (3.6). Moreover,

\[ W(k, k', p) = e^{i(k_1' + k_2' - p_2)} + e^{i(k_1' + k_2' - p_3)} + e^{i(k_1 + k_2 + p_2)} + e^{i(k_1 + k_2 + p_3)} - e^{i(k_1 + k_2 + p_2)} - e^{i(k_1' + k_2' - p_3)} - e^{i(k_1' + k_2' - p_2)} - e^{i(k_1 + k_2 + p_3)}, \] (B.3)

while \( f_r(k, p) \), for \( r = 1, \ldots, 4 \), is defined by

\[ f_1(k, p) = e^{i(k_1 + k_2)}(e^{ip_1} + e^{ip_2}) - 2 + ie^{ik_2}(1 + e^{ip_2}) - ie^{ik_1}(e^{ip_1} + 1), \]
\[ f_2(k, p) = 2e^{i(k_1 + k_2)} - (e^{ip_1} + e^{-ip_2}) + ie^{ik_2}(e^{-ip_1} + 1) - ie^{ik_1}(1 + e^{-ip_2}), \]
\[ f_3(k, p) = e^{i(k_1 + k_2)}(1 + e^{ip_2}) - (e^{-ip_1} + 1) + ie^{ik_2}(e^{-ip_1} + e^{ip_2}) - 2ie^{ik_1}, \]
\[ f_4(k, p) = e^{i(k_1 + k_2)}(e^{ip_1} + 1) - (1 + e^{-ip_2}) + 2ie^{ik_2} - ie^{ik_1}(e^{ip_1} + e^{-ip_2}). \]

Observe for later convenience that

\[ W(k, k', 0) = 2(e^{ik_1} - e^{ik_1'})(e^{ik_2} - e^{ik_2'}), \] (B.4)

and that

\[ f_r(k, 0) = -2\mu(k). \] (B.5)

In the following, we shall first explain how to obtain (B.2), and then we will analyze its behavior close to \( p = 0 \) and \( p = (\pi, \pi) \), so that, by using (A.1), we will be able to identify the values of \( A(\lambda) \) and of \( \nu(\lambda) \), at first non-trivial order in \( \lambda \).

**B.1. Proof of (B.2)**

We start from (B.1). Let us first look at the term \( \mathcal{E}_d(X_e^{(1)}; E_e) \). Given a quartic polynomial of the Grassmann variables, of the form

\[ W(\psi) = \sum_{x_1, \ldots, x_4} a(x_1, \ldots, x_4) \psi_{x_1}^+ \psi_{x_2}^- \psi_{x_3}^+ \psi_{x_4}^- \]

we define its ‘linearization’ \( \overline{W} \) as:

\[ \overline{W}(\psi) = \sum_{x_1, \ldots, x_4} a(x_1, \ldots, x_4)[-\psi_{x_1}^+ \psi_{x_2}^- g(x_4 - x_3) - \psi_{x_3}^+ \psi_{x_4}^- g(x_2 - x_1)] + \psi_{x_2}^+ \psi_{x_3}^- g(x_4 - x_1) + \psi_{x_1}^+ \psi_{x_4}^- g(x_2 - x_3)]. \] (B.6)
Note that $\mathcal{W}$ is obtained from $W$ by ‘contracting’ (in all possible ways) two out of the four Grassmann fields, the contraction corresponding to the selection of a pair of $\psi^+ \psi^-$ fields, and by the replacement of the selected pair by its average with respect to $\mathcal{E}_0(\cdot)$. Due to the truncated expectation, one then has

$$\mathcal{E}_0(\mathcal{T}_e^{(1)}; E; E) = \mathcal{E}_0(\mathcal{T}_e^{(1)}; E; E).$$

If, e.g. $e$ is of type 1,

$$\mathcal{T}_e^{(1)} = g(v_1)(\psi_{x+1,0}^+ \psi_{x-1,0}^- + \psi_{x+1,0}^- \psi_{x-1,0}^+) + 2g(v_3)\psi_x^+ \psi_x^- - g(v_2)(\psi_{x+1,0}^+ \psi_{x-1,0}^- + \psi_{x+1,0}^- \psi_{x-1,0}^+) - g(v_4)(\psi_{x+1,0}^+ \psi_{x-1,0}^- + \psi_{x+1,0}^- \psi_{x-1,0}^+).$$

(B.8)

Since, by symmetry, all the edges $e$ have the same probability, $1/4$, of being occupied by a dimer, (3.31) for $\lambda = 0$ gives $1/4 = -\mathcal{E}_0(E_e)$, so that

$$g(v_e) = \mathcal{E}_0(\psi_{x+1}^+ \psi_x^-) = \frac{1}{4K_r}.$$  

(B.9)

Therefore, if $e$ is of type 1,

$$\mathcal{T}_e^{(1)} = \frac{1}{4}(\psi_{x+1,0}^+ \psi_{x-1,0}^- + \psi_{x+1,0}^- \psi_{x-1,0}^+) - 2\psi_x^+ \psi_x^- + \frac{1}{4}(\psi_{x+1,0}^+ \psi_{x-1,0}^- + \psi_{x+1,0}^- \psi_{x-1,0}^+) - \psi_x^+ \psi_{x-1,0}^+ \psi_{x-1,0}^- - \psi_x^- \psi_{x+1,0}^- \psi_{x+1,0}^+)$$

$$= \frac{1}{4} \int \frac{dp}{(2\pi)^2} e^{ipx} \int \frac{dk}{(2\pi)^2} \hat{\psi}_{k+p}^+ \hat{\psi}_k f(k, p).$$

(B.11)

Now, recall that

$$E_e = -K_r \psi_{y+1}^+ \psi_{y+c,0}^- = -K_r \int \frac{dp}{(2\pi)^2} e^{-ipy} \int \frac{dk}{(2\pi)^2} \hat{\psi}_k \psi_{k+p} e^{-i\nu(k+p)}.$$  

(B.12)

By using (B.11) and (B.12), the Wick rule and the fact that $\mathcal{E}_0(\hat{\psi}_k^- \hat{\psi}_k^+) = (2\pi)^2 \delta(k - k') \mu(k)$, we find that the Fourier transform of $-\lambda \mathcal{E}_0(\mathcal{T}_e^{(1)}; E; E)$, computed at $p$, equals

$$-\lambda \sum_x e^{-ipx} \mathcal{E}_0(\mathcal{T}_e^{(1)}; E; E) = \lambda K_r \int \frac{dk}{(2\pi)^2} \frac{1}{\mu(k)(k+p)} e^{-i\nu(k+p)} f(k, p).$$

(B.13)

Next, we compute $\lambda \mathcal{E}_0(E_e; E; E)$. Among the different ways of contracting the fields in the application of the fermionic Wick rule to form connected diagrams, either two of the four fields in a monomial of $V_1$ are contracted among themselves, or they are all contracted with fields in $E_e, E_e'$, $V_j$. One can check that the contributions of the former type, combined with the zero-order diagram $\mathcal{E}_0(E_e; E; E)$, altogether give

https://doi.org/10.1088/1742-5468/aa5d1f

34
where $\mathcal{E}_0$ is the Grassmann Gaussian expectation defined in a way analogous to (3.11), with the difference that $-(\psi^+, K_0 \psi^-)$ is replaced by $-(\psi^+, K_0 \psi^-) + \lambda \mathcal{V}_0(\psi)$. Using (B.9) we find that

$$\mathcal{E}_0(E_v; E_e) = K_r K_r' \mathcal{E}_0(\psi^+ \psi^-_{x+y}; \psi_1^+ \psi^-_{x+y+[v, v']}).$$

(B.16)

which is nothing but $-(\psi^+, K_0 \psi^-)$ itself. Therefore,

$$\mathcal{E}_0(E_v; E_e) = \frac{-K_r K_r' g(v_r - x + y)g(v_r + x - y)}{(1 + \lambda)^2}.$$ 

(B.17)

Taking the Fourier transform, this gives

$$-(1 - 2\lambda)K_r K_r' \int \frac{dk}{(2\pi)^2} \frac{e^{-ik_v - i(k+p)v_r}}{\mu(k)\mu(k + p)} + O(\lambda^2).$$

(B.18)

Finally, we consider the contributions to $\lambda \mathcal{E}_0(E_v; E_e; V_4)$ from the diagrams where two fields in $V_4$ are contracted with the two fields of $E_e$ and the remaining two are contracted with $E_e'$. It is convenient to symmetrize $V_4$ by rewriting, after taking the Fourier transform,

$$V_4(\psi) = -\frac{1}{2} \int \frac{dp}{(2\pi)^2} \int \frac{dk}{(2\pi)^2} \int \frac{dk'}{(2\pi)^2} \int \frac{dk''}{(2\pi)^2} \mathcal{V}_0 \mathcal{V}_0^* W(k, k', p),$$

(B.19)

with $W$ as in (B.3). Now, by using (B.19), (B.12), and the analogous expression for $E_e'$, we find that the Fourier transform of the sum of the contributions to $\lambda \mathcal{E}_0(E_v; E_e; V_4)$ from connected diagrams, such that none of the fields of $V_4$ are contracted among themselves, is equal to

$$-2\lambda K_r K_r' \int \frac{dk}{(2\pi)^2} \int \frac{dk'}{(2\pi)^2} \frac{W(k, k', p)e^{-iv_r(k' - p) - iv_r(k + p)}}{\mu(k)\mu(k + p)\mu(k')\mu(k' + p)}.$$ 

(B.20)

Now, recall that, from (B.1), $G_{r, r'}^{(0,2)}(p)$ at first order in $\lambda$ is given by the sum of (B.18), (B.20), (B.13), plus the term in (B.13), but with $e, e'$ interchanged, which gives (B.2), as desired.

### B.2. Behavior for $p \sim 0$

We want to identify the discontinuity of $G_{r, r'}^{(0,2)}(p)$ at $p = 0$ and, by using (A.1), identify the pre-factor $A(\lambda)$ at lowest non-trivial order in $\lambda$. We consider the case $r = r' = 1$: any choice of $(r, r')$ is equally good for computing $A(\lambda)$, and the case $r = r' = 1$ is, possibly, the simplest.

Let us first look at the first term on the right-hand side of (B.2), which, for $r = r' = 1$, is equal to

https://doi.org/10.1088/1742-5468/aa5d1f
\[-(1 - 2\lambda) \int \frac{dk}{(2\pi)^2} \frac{1}{\mu(k)\mu(k + p)}, \quad \text{(B.21)}\]

plus an error term that vanishes as \( p \to 0 \). The integral in (B.21) can be evaluated by proposition A.3, and equals

\[-\frac{1 - 2\lambda}{4\pi} \text{Re} \left[ \frac{D_-(p)}{D_+(p)} \right], \quad \text{(B.22)}\]

plus terms that are continuous at \( p = 0 \).

Next we look at the term in the second line of (B.2). We can set \( p = 0 \) in \( W(k, k', p) \), up to an error term that vanishes for \( p \to 0 \). This is because the integral diverges at like \( \log |p|^2 \), so that the error term is \( O(|p|\log |p|^2) \). Then, by using proposition A.3, the second line of (B.2) for \( r = r' = 1 \) reduces to

\[-8\lambda(I_{(1,1)}(p)I_{(0,0)}(p) - I_{(1,0)}(p)I_{(0,1)}(p)) \quad \text{(B.23)}\]

plus terms that vanish as \( p \to 0 \). In order to evaluate this expression, we use (A.6), which we rewrite as

\[ I_{(a,b)}(p) = \frac{1}{8\pi} \left[ \frac{D_-(p)}{D_+(p)} + (-1)^{a+b} \frac{D_+(p)}{D_-(p)} \right] + U_{(a,b)} + R_{(a,b)}(p), \]

and we recall that \( R_{(a,b)} \) vanishes continuously at \( p = 0 \). Omitting terms that are continuous at \( p = 0 \), (B.23) equals

\[-\frac{2\lambda}{\pi} \text{Re} \left[ \frac{D_-(p)}{D_+(p)} (U_{(0,0)} + U_{(1,1)} - U_{(0,1)} - U_{(1,0)}) \right]. \quad \text{(B.24)}\]

A simple computation shows that

\[ U_{(0,0)} = \frac{1}{4} \left( 1 - \frac{2}{\pi} \right), \quad U_{(1,1)} = 0, \quad U_{(0,1)} = \frac{i}{4\pi}, \quad U_{(1,0)} = -\frac{i}{4\pi} \]

so that (B.24) reduces to

\[-\frac{\lambda}{2\pi} \left( 1 - \frac{2}{\pi} \right) \text{Re} \left[ \frac{D_-(p)}{D_+(p)} \right]. \quad \text{(B.25)}\]

Finally, it is easy to see that the term in the last line of (B.2) is continuous at \( p = 0 \). Indeed, as above, we can replace \( f_1(k, p) \) by \( f_1(k, 0) \), up to an error term of order \( O(|p|\log |p|^2) \). Now, recalling that \( f_1(k, 0) = -2\mu(k) \), we see that this term simplifies with the factor \( \mu(k) \) in the denominator: after the simplification, we are left with an absolutely convergent integral.

Altogether, from (B.22) and (B.25)

\[ \bar{G}^{(0,2)}_{r, r'}(p) = -\frac{1}{4\pi} \left( 1 - \frac{4\lambda}{\pi} \right) \text{Re} \left[ \frac{D_-(p)}{D_+(p)} \right], \quad \text{(B.26)}\]

where we omitted terms that are either continuous at \( p = 0 \) or are \( O(\lambda^2) \). In view of (A.1), we have

https://doi.org/10.1088/1742-5468/aa5d1f
\[ A(\lambda) = 1 - \frac{4}{\pi} \lambda + O(\lambda^2). \]  

(B.27)

### B.3. Behavior for \( p \sim (\pi, \pi) \)

In order to compute \( \nu = \nu(\lambda) \) at first order, we use the second line of (A.1) that, if expanded at first order in \( \lambda \), and defining the coefficients \( \nu_1 \) and \( b_1 \) via \( \nu(\lambda) = 1 + \nu_1 \lambda + O(\lambda^2) \) and \( B(\lambda)\Gamma(2 - \nu(\lambda))/\Gamma(\nu(\lambda)) = 1 + b_1 \lambda + O(\lambda^2) \), reads

\[ G^{(0,2)}_{r, r'}((\pi, \pi) + q) = \frac{t_{r, r'}}{2\pi} \left[ -(1 + b_1 \lambda) \log \left( \frac{|q|}{2} \right) - \nu_1 \lambda \log^2 \left( \frac{|q|}{2} \right) \right], \tag{B.28} \]

up to terms that are continuous at \( q = 0 \), and/or of the order \( O(\lambda^2) \). From this equation, it is apparent that \( \nu_1 \) can be read from the most divergent contribution at order \( O(\lambda) \), i.e. from the contribution to \( G^{(0,2)}_{r, r'}((\pi, \pi) + q) \) that diverges as \( \log^2|q| \), as \( q \to 0 \), at first order in \( \lambda \).

For simplicity, we consider again the case \( r = r' = 1 \), in which case \( t_{r, r'} = t_{1,1} = 1 \).

We start from (B.2) computed at \( p = (\pi, \pi) + q \), and we observe that neither the term in the first line nor the one in the third line give a contribution to \( \nu_1 \), since they diverge as \( \log|q| \), as \( q \to 0 \).

It remains to consider the second line of (B.2), which can be rewritten, up to terms that vanish as \( q \to 0 \), as

\[ 4\lambda \int \frac{dk}{(2\pi)^2} \int \frac{dk'}{(2\pi)^2} \frac{(e^{ik_1} - e^{ik'_1})(e^{ik_2} - e^{ik'_2})}{\mu(k)(k + (\pi, \pi) + q)\mu(k')(k' - (\pi, \pi) - q)}, \tag{B.29} \]

where we use that

\[ W(k, k', (\pi, \pi)) = -W(k, k', 0) = -2(e^{ik_1} - e^{ik'_1})(e^{ik_2} - e^{ik'_2}). \]

The denominator has zeros when \( k \) and \( k' \) are close either to \((0, 0)\) or to \((\pi, \pi)\). However, when \( k, k' \) are both close to \((0, 0)\) or both close to \((\pi, \pi)\), the singularity is partially canceled by the fact that the numerator in (B.29) vanishes there: as a consequence, the contributions to the integral in (B.29) from the regions where \( k, k' \) are both close to \((0, 0)\) or both close to \((\pi, \pi)\) diverge less severely than \( \log^2|q| \), as \( q \to 0 \).

Therefore, the relevant contribution is from the region \( k \sim 0, k' \sim (\pi, \pi) \), or vice versa, in which case the numerator \( (e^{ik_1} - e^{ik'_1})(e^{ik_2} - e^{ik'_2}) \) in (B.29) is equal to 4, up to terms that, once integrated in \( k, k' \), give a contribution that is more regular than \( (\log|q|)^2 \). We make a similar replacement in the denominator: consider, e.g. the case \( k \sim 0, k' \sim (\pi, \pi) \), and rewrite \( k' = (\pi, \pi) + k'' \), so that both \( k \) and \( k'' \) are in the neighborhood of the origin. Then, we can rewrite the denominator \( \mu(k)(k + (\pi, \pi) + q)\mu(k')(k' - (\pi, \pi) - q) \) in (B.29) as its linearization, \( D_\pm(k)D_\pm(k + q)D_\pm(k' - q) \), plus a rest that, once integrated in \( k, k' \), gives a contribution that is more regular than \( (\log|q|)^2 \). We recall that \( D_\pm(k) \) was defined in (3.10) and in, particular, \( D_+(k) = -D_-(k) \). A similar argument can be repeated in the case where \( k \sim (\pi, \pi), k' \sim 0 \), which gives exactly the same dominant contribution (and, therefore, can be accounted for by multiplying the result of the first case by an overall factor 2).
In conclusion, the dominant contribution (for \( q \) small) to (B.29) is

\[
32\lambda \left| \int_{|k|<1} \frac{dk}{(2\pi)^2} \frac{1}{D_+(k)D_-(k + q)} \right|^2.
\]  

(B.30)

Always at dominant order, we can restrict the integration to \( |k| > 2|q| \) (the contribution from the complementary set is \( O(1) \)) and replace \( D_+(k)D_-(k + q) \) by \( -|D_+(k)|^2 = -2|k|^2 \) there. Then, the integral (B.30) gives, at dominant order,

\[
32\lambda \left( \int_{2|q|<|k|<1} \frac{dk}{2(2\pi)^2} \frac{1}{|k|^2} \right)^2 = \frac{2}{\pi^2} \lambda (\log(2|q|))^2.
\]  

(B.31)

By comparing this expression with the term of order \( \log^2|q| \) in (B.28), and recalling that \( t_{1,1} = 1 \), we conclude that \( \nu_1 = -4/\pi \), that is

\[
\nu(\lambda) = 1 - \frac{4}{\pi} \lambda + O(\lambda^2),
\]  

(B.32)
as desired.

Appendix C. Ward identities for the reference model

In this section we sketch the proof of the Ward identities (5.9) and (5.11), and of the identity (6.15) for the critical exponent \( \nu \). A full proof can be found in [6] and references therein.

C.1. Ward identities

The starting point in the derivation of the Ward identities is a ‘chiral-gauge transformation’ of the Grassmann fields in the reference model’s generating functional: that is, given \( \mathcal{J} \in \{ \pm \} \), we perform the following change of variables:

\[
\psi_{\pm,\sigma}^\alpha \to e^{\pm i\alpha_{\sigma,\alpha}} \psi_{\pm,\sigma}^\alpha, \quad \psi_{\pm,-\sigma}^\alpha \to \psi_{\pm,-\sigma}^\alpha,
\]  

(C.1)
in the numerator of the right-hand side of (5.1). The generating functional is invariant under this change of variables; therefore, the variation of the right-hand side of (5.1) with respect to \( \alpha_{\sigma} := \{ \alpha_{\sigma,\alpha} \}_{\alpha \in \Lambda} \) is zero. In the following, we intend to compute this variation, take its derivative with respect to \( \alpha_{\sigma} \), and set \( \alpha_{\sigma} \equiv 0 \). The resulting identity can be thought of as the generating function for a hierarchy of Ward identities.

Note that the interaction \( \mathcal{V}(\sqrt{Z} \psi) \) on the right-hand side of (5.1) is invariant under the transformation (C.1), and so is the source term \( Z^{(1)}(J^{(1)}, \rho^{(1)}) \).

Moreover,

\[
Z^{(2)}(J^{(2)}, \rho^{(2)}) \to Z^{(2)} \sum_{\omega = \pm} \int_{\Lambda} dx \, J^{(2)}_{\pm,\sigma} \rho^{(2)}_{x,\omega} e^{i\omega \alpha_{\pm,\sigma}},
\]  

(C.2)

\[
Z(\psi^+, \phi^-) \to Z \int_{\Lambda} dx (\psi^+_{x,\sigma} \phi^-_{x,\omega} e^{i\omega \alpha_{\sigma,\omega}} + \psi^+_{x,-\sigma} \phi^-_{x,-\omega}),
\]  

(C.3)
Finally, and most importantly, the Gaussian integration is also affected by the chiral-gauge transformation: in fact, $P_Z^{\pm N}(d\psi)$ can be formally\textsuperscript{11} written as

$$P_Z^{\pm N}(d\psi) = \frac{1}{\mathcal{N}} \exp \left\{ -Z \sum_{\omega} \int_{\Lambda} dx \psi_{x,\omega}^+(D_N\psi_{x,\omega}^-)(x) \right\} \prod_{\omega=\pm} \prod_{x \in \Lambda} d\psi_{x,\omega}^+ d\psi_{x,\omega}^-,$$  

(C.5)

where $\mathcal{N}$ is a normalization constant and

$$(D_N\psi_{x,\omega}^\pm)(x) := \pm \frac{1}{L^2} \sum_{k \in D} e^{\pm ikx} (\chi_N(k))^{-1} D_\omega(k) \psi_{k,\omega}^\pm.$$  

(C.6)

Under the chiral-gauge transformation, the ‘Grassmann measure’

$$\prod_{\omega=\pm} \prod_{x \in \Lambda} d\psi_{x,\omega}^+ d\psi_{x,\omega}^-$$

on the right-hand side of (C.5) is invariant, and so is the term $\int_{\Lambda} dx \psi_{x,-\omega}^+(D_N\psi_{x,-\omega}^-)(x)$ at the exponent, while

$$\int_{\Lambda} dx \psi_{x,\omega}^+(D_N\psi_{x,-\omega}^-)(x) \to \int_{\Lambda} dx e^{\pm ikx} \psi_{x,\omega}^+(D_N e^{\pm ikx} \psi_{x,-\omega}^-)(x)$$

$$= \int_{\Lambda} dx \psi_{x,\omega}^+(D_N\psi_{x,-\omega}^-)(x) + i \int_{\Lambda} dx \alpha_{x,\omega}[(D_{\rho}^{(1)})(x) + \delta T_\omega(x)] + O(\alpha^2),$$  

(C.7)

where

$$(D_{\rho}^{(1)})(x) = -\frac{1}{L^2} \sum_{k,p \in D} e^{ipx} D_\omega(p) \hat{\psi}_{k+p,\omega}^+ \hat{\psi}_{k,\omega}^-,$$  

(C.8)

$$\delta T_\omega(x) = \frac{1}{L^1} \sum_{k,p \in D} e^{ipx} \hat{\psi}_{k+p,\omega}^+ C_\omega(k+p,k) \hat{\psi}_{k,\omega}^-,$$  

(C.9)

and

$$C_\omega(k+p,k) := [\chi_N^{-1}(k) - 1] D_\omega(k) - [\chi_N^{-1}(k+p) - 1] D_\omega(k+p).$$  

(C.10)

Putting things together, and imposing that the variation of (5.1) vanishes at first order in $\alpha_\omega$, we find, letting

$$\mathcal{V}(\psi, J, \phi) := \mathcal{V}(\sqrt{Z}\psi) + \sum_{j} Z^{(j)}(J^{(j)}, \rho^{(j)}) + Z[(\psi^+, \phi^-) + (\phi^+, \psi^-)],$$  

(C.11)

that

\textsuperscript{11} The reason why (C.5)–(C.6) are ‘formal’ is that $(\chi_N(k))^{-1}$ is infinite if $k$ is outside the support of $\chi_N$. In order to make sense of these and the following formulas, one should introduce a function $\chi_N^{\varepsilon}$ of full support, such that $\lim_{\varepsilon \to 0} \chi_N^{\varepsilon}(k) = \chi_N(k)$. One should perform all computations keeping $\varepsilon$ fixed, and then send $\varepsilon \to 0$ first, before the removal of all the other cut-off parameters. In this appendix, we neglect this issue; for more details, see [7].
By taking derivatives w.r.t. $J$ and $\phi$, and then setting the external sources to zero, we generate a hierarchy of Ward identities. For example, by deriving w.r.t. $z$, $\phi^+ - \psi^-$ and $y$, $\phi^+ + \psi^+$, and then setting the external sources to zero, we find

\begin{equation}
\delta_{\omega, z} \omega^2 \langle \psi_{y, \omega} \psi_{z, \omega} \rangle_{L, N, a} - \delta_{\omega, y} \omega^2 \langle \psi_{x, \omega} \psi_{y, \omega} \rangle_{L, N, a} - Z^3 \langle (D\rho_\omega^{(1)})(x) \rangle_{L, N, a} - Z^3 \langle \delta T_{\omega}(x) \rangle_{L, N, a} = 0,
\end{equation}

where $\langle A(\psi) \rangle_{L, N, a} := \int P^\leq_N(\psi) e^{\chi N}\psi A(\psi) \int P^\leq_N(\psi) e^{\chi N}$, and the semicolon indicates truncated expectation (note that in the second line the truncated expectations are equal to the un-truncated ones, simply because $\langle \delta T_{\omega}(x) \rangle_{L, N, a} = 0$).

After taking the Fourier transform and sending $L, N, a \to \infty$, we get

\begin{equation}
\delta_{\omega, z} \omega^2 \langle \hat{G}_{\omega, \omega}^{(2)}(k + p) - \hat{G}_{\omega, \omega}^{(2)}(k) \rangle + \frac{Z}{Z^{(1)}} D\omega(p) \hat{G}_{\omega, \omega}^{(2)}(k, p) - \frac{Z}{Z^{(1)}} \hat{A}_{\omega, \omega}(k, p) = 0,\end{equation}

where

\begin{equation}
\hat{A}_{\omega, \omega}(k, p) = \lim_{L, N, a \to \infty} \frac{Z^{(1)}}{L^4} \sum_{q \in D} C_{\omega}(q + p, q) \left\langle \hat{\psi}_{q + p, \omega, \omega}^+ \hat{\psi}_{q, \omega}^- \hat{\psi}_{k + p, \omega}^+ \hat{\psi}_{k, \omega}^- \right\rangle_{L, N, a},
\end{equation}

and the limit on the right-hand side is meant as the limit $a \to 0$ first, then $N \to \infty$, then $L \to \infty$. By summing (C.14) over $\omega$, we will eventually get (5.9). Of course, the subtle issue is to compute $\hat{A}_{\omega, \omega}(k, p)$ (see below).

Remark 9. The term $\hat{A}_{\omega, \omega}(k, p)$ is referred to as an ‘anomaly term’: formally, it would be zero if we replaced the cut-off function $\chi_N$ appearing in the definition of $C_{\omega}(k + p, k)$ by 1. Of course, there is an exchange of limits involved: we first need to compute the expression on the right-hand side of (C.15) under the limit sign, and then take the limit of removed cut-offs. In order to compute the right-hand side of (C.15), we can use a multi-scale analysis similar to the one used in the computation of the free energy and the correlation functions of the interacting dimer model (see [25]) and of the reference model (see, e.g. [7] or [6]). Under RG iterations, the operator $\delta T_{\omega}$ appears to be marginal [7, 8], with a non-trivial flow from the ultraviolet scale, down to the deep infrared: this induces a non trivial flow of the anomaly term, which converges to a finite value (its ‘infrared fixed point’), that is non-vanishing in the limit of removed cut-offs. The fact that the anomaly term does not vanish in this limit is visible already at first order in perturbation theory.

In addition to the Ward identity (C.14) for the vertex function, we can get another identity for the density–density correlations, by deriving (C.12) with respect to $J_{y, \omega}^{(1)}$ and then setting the external sources to zero. In this case, after taking the Fourier transform and the limit of removed cut-offs, we obtain

\begin{equation}
D\omega(p) \hat{S}_{\omega, \omega}^{(1, 1)}(p) = \hat{B}_{\omega, \omega}(p),
\end{equation}

\begin{equation}
\int P^\leq_N(\psi) e^{\chi N}\psi \int P^\leq_N(\psi) e^{\chi N} = 0.
\end{equation}

\[\int P^\leq_N(\psi) e^{\chi N}\psi \int P^\leq_N(\psi) e^{\chi N} = 0.\]
\[ \hat{B}_\omega(p) = \lim_{L,N,a \to \infty} \frac{Z^{(1)}}{L^6} \sum_{q,k \in \mathcal{D}} C_\omega(q + p, q) \left( \hat{\psi}_q^+ \hat{\psi}_{q+p,\omega} \hat{\psi}_{k,\omega}^+ \hat{\psi}_{k-p,\omega} \right)_{L,N,a} \]  

(C.17)

is an anomaly term. Its computation, sketched below, leads to (5.11).

C.2. The anomaly terms

The anomaly terms have been computed in a series of previous works, starting from [7, 8]. In the presence of a non-local interaction potential, such as the one considered here (recall (5.5)), it has a very explicit form: for instance, \( \hat{A}_{\omega'}(k, p) \) is equal to an explicit pre-factor, linear in \( \lambda_\infty \), times \( G_{R_{\omega},\omega'}^{(2,1)}(k, p) \) (see (C.23) below). The fact that the pre-factor is exactly linear in \( \lambda_\infty \), i.e. that all its contributions beyond first-order perturbation theory vanish in the removed cut-offs limit, is a phenomenon known as the ‘anomaly non-renormalization’, first proved in this context in [47] (see also [6]).

Here, we informally discuss the main ideas of the proof and explain how to compute the anomaly terms.

For definiteness, let us consider the anomaly \( \hat{A}_{\omega}(k, p) \) first: the expression on the right-hand side of (C.15), under the limit sign, can be computed by a multi-scale analysis, similar to the one discussed in [25] (see [6] for details). The outcome is that, if \( k, p, k + p \neq 0 \), then \( \hat{A}_{\omega}(k, p) \) is analytic in \( \lambda_\infty \), uniformly in \( N, L, a \). Note that, by the support properties of \( C_\omega(q + p, q) \), in order for the summand not to vanish, both \( q \) and \( p + q \) must be ‘on scale \( N \)’, that is, for any fixed \( p \) and \( N \) large enough, \( 2^{N-1} \leq \left| q \right|, \left| q + p \right| \leq 2^{N+2} \). Therefore, the sum over \( q \) on the right-hand side of (C.15) can be performed under this constraint.

Thanks to the analyticity in \( \lambda_\infty \), we can expand \( \hat{A}_{\omega}(k, p) \) in series, thus finding

\[ \hat{A}_{\omega}(k, p) = \lim_{L,N,a \to \infty} \frac{Z^{(1)} Z^2}{L^4} \sum_{q \in \mathcal{D}} \sum_{n \geq 0} \frac{1}{n!} C_\omega(q + p, q) \times \left( \hat{\psi}_{q+p,\omega} \hat{\psi}_{q,\omega}^+ \hat{\psi}_{k,\omega}^+ \hat{\psi}_{k-p,\omega} \right)_{L,N,a} \]  

(C.18)

where \( \{ \mathcal{V} \} \) is a shorthand notation for \( \mathcal{V} \mathcal{V}_1 \cdots \mathcal{V} \), and \( \left( \cdot \right)^0_{L,N,a} \) is the unperturbed integration, i.e. \( \left( \cdot \right)^0_{L,N,a} := \int \mathcal{P}_Z^{\leq N}(d\psi)(\cdot) \), whose expectations can be computed by the fermionic Wick rule. Now, one can easily check that the 0th-order term, i.e. the term with \( n = 0 \) on the right-hand side of (C.18), vanishes in the removed cut-off limit. The higher-order terms can be of two types: either the two Grassmann fields \( \hat{\psi}_{q+p,\omega}, \hat{\psi}_{q,\omega}^+ \) are contracted with (two of the four fields of) the same interaction term \( \mathcal{V} \), or with (the fields of) two different interaction terms. Correspondingly, we can write \( \hat{A}_{\omega}(k, p) = (I) + (II) \), where, recalling that \( \hat{\psi}_0(p) \) is the Fourier transform of the interaction potential, which is rotationally invariant and such that \( \hat{\psi}_0(0) = 1 \),
Haldane relation for interacting dimers

\[ H_{L,N,a} = \lim_{L,N,a \to \infty} \frac{\lambda \hat{b}_0(p)}{L^6} \sum_{q \in D} C_{\omega}(q + p, q) Z^2 \langle \hat{\psi}_{q+p,p,\omega}^{-} \hat{\psi}_{q,\omega}^{+} \rangle_{L,N,a} \times \frac{1}{L^4} \sum_{q' \in D} \sum_{n \geq 1} \frac{Z^{(1)} Z^2}{(n-1)!} \langle \hat{\psi}_{q'+p,\omega}^{+} \hat{\psi}_{q,\omega}^{-} \rangle_{L,N,a} \]

and

\[ (II) = \lim_{L,N,a \to \infty} \frac{1}{L^4} \sum_{q \in D} C_{\omega}(q + p, q) \langle \hat{\psi}_{q+p,\omega}^{+} \hat{\psi}_{q,\omega}^{-} \rangle_{L,N,a} \times \sum_{n \geq 2} \frac{Z^{(1)} Z^2}{(n-2)!} \langle \hat{\psi}_{q+p,\omega}^{+} \hat{\psi}_{q,\omega}^{-} \rangle_{L,N,a}. \]

Let us focus on (I) first. After summation over \( n \), the third line of (C.19) can be explicitly re-written as

\[ \frac{1}{L^4} \sum_{q' \in D} Z^{(1)} Z^2 \langle \hat{\psi}_{q'+p,\omega}^{+} \hat{\psi}_{q,\omega}^{-} \rangle_{L,N,a}, \]

whose removed cut-off limit equals \( \hat{G}_{R,\omega}(k, p) \). Therefore,

\[ (I) = \lambda \hat{b}_0(p) \hat{H}_{\omega}(p) \hat{G}_{\omega}(k, p), \]

where

\[ \hat{H}_{\omega}(p) = - \lim_{N \to \infty} \int_{\mathbb{R}^2} \frac{dq}{(2\pi)^2} C_{\omega}(q + p, q) \frac{\chi_{\omega}(q) \chi_{\omega}(q + p)}{D_{\omega}(q) D_{\omega}(q + p)}. \]

Recall that the integrand is non-vanishing only if \( q \) and \( q + p \) are on scale \( N \). Therefore, the integrand vanishes pointwise in the limit \( N \to \infty \). However, the limit of the integral is not zero: a straightforward, but very instructive, computation shows that

\[ \hat{H}_{\omega}(p) = - \frac{1}{8\pi} D_{\omega}(p), \]

from which we infer that \( (I) = - \lambda \hat{b}_0(p) \hat{H}_{\omega}(p) \hat{G}_{\omega}(k, p) \).

Let us now turn to (II). The key fact is that all its contributions vanish in the removed cut-off limit. At a perturbative level, this can be checked by looking at the Feynman diagram expansion on the right-hand side of (C.20): the constraint that the momenta \( q, q + p \) are on scale \( N \), while the external momenta \( k, k + p \) are fixed, induces a ‘dimensional gain’ in the dimensional estimate of the values of the diagrams, which makes them vanish in the removed cut-off limit, at a speed at least \( 2^{-\theta N} \) for a suitable \( \theta \in (0, 1) \). The reader can easily check this fact for the lowest-order diagrams. For a general, non-perturbative, proof, see [6, 47].

https://doi.org/10.1088/1742-5468/aa5d1f
In conclusion,
\[ \hat{A}_{\omega', \omega}(k, p) = -\frac{\lambda_\infty}{8\pi} D_{\omega'}(p) \hat{\delta}_0(p) \hat{G}^{(2,1)}_{\omega', \omega}(k, p). \]  
(C.23)

Plugging this back into (C.14) we get
\[
\frac{Z}{Z^{(1)}} \left[ D_{\omega}(p) \hat{G}^{(2,1)}_{R, \omega, \omega}(k, p) + \frac{\lambda_\infty}{8\pi} \hat{\delta}_0(p) D_{\omega}(p) \hat{G}^{(2,1)}_{-\omega, \omega}(k, p) \right] = \hat{G}^{(2)}_{R, \omega}(k) - \hat{G}^{(2)}_{R, \omega}(k + p),
\]
\[
\frac{Z}{Z^{(1)}} \left[ D_{-\omega}(p) \hat{G}^{(2,1)}_{R, -\omega, \omega}(k, p) + \frac{\lambda_\infty}{8\pi} \hat{\delta}_0(p) D_{-\omega}(p) \hat{G}^{(2,1)}_{-\omega, \omega}(k, p) \right] = 0.
\]  
(C.24)

and summing the two equations we get (5.9), as desired.

Similarly, we find that the anomaly term \( \hat{B}_{\omega', \omega}(p) \) in (C.17) is
\[
\hat{B}_{\omega', \omega}(p) = \hat{H}_{\omega'}(p) \left[ \frac{(Z^{(1)})^2}{Z^2} \delta_{\omega', \omega} + \lambda_\infty \hat{\delta}_0(p) \hat{G}^{(1,1)}_{R, -\omega, \omega}(p) \right],
\]  
(C.25)

with \( \hat{H}_{\omega'}(p) \) as in (C.22). By plugging (C.25) into (C.16), we immediately get (5.11).

C.3. The critical exponent \( \nu \)

In this subsection, we give a sketch of the proof of the identity (6.15). We proceed as in [6, section 4.2]. The explicit form of the critical exponent follows from an exact computation of the ‘mass–mass’ correlation function \( S^{(2,2)}_{R, \omega, \omega}(x, y) \), which is as follows. We let
\[
G^{(4)}_{R, \omega}(x, y, u, v) := Z^4 \lim_{L, N, a \to \infty} \langle \psi^+_{\omega, x, \omega} \psi^+_{\omega, y, -\omega} \psi^-_{\omega, u, -\omega} \psi^-_{\omega, v, \omega} \rangle_{L, N, a}.
\]  
(C.26)

Note that \( G^{(4)}_{R, \omega} \) is related to \( S^{(2,2)}_{R, \omega, \omega} \) via the identity
\[
G^{(4)}_{R, \omega}(x, y, x, y) = \frac{Z^4}{(Z^{(1)})^2} S^{(2,2)}_{R, -\omega, \omega}(x, y).
\]  
(C.27)

The key observation is that \( G^{(4)}_{\omega} \) and the dressed propagator \( G^{(2)}_{\omega} \) satisfy a system of two equations, obtained by combining the Ward identities with the Schwinger–Dyson equation (see below for details):
\[
D^x_{\omega} G^{(2)}_{R, \omega}(x, 0) = Z\delta(x) - \lambda_\infty F_{\omega, -}(x) G^{(2)}_{R, \omega}(x, 0),
\]  
(C.28)
\[
D^x_{\omega} G^{(4)}_{R, \omega}(x, y, u, v) = Z\delta(x - v) G^{(2)}_{R, -\omega}(y, u) + \lambda_\infty [F_{\omega, +}(x - y) - F_{\omega, +}(x - u) - F_{\omega, -}(x - v)] G^{(4)}_{R, \omega}(x, y, u, v),
\]  
(C.29)

where \( D^x_{\omega} \) was defined in (5.4), and \( F_{\omega, \varepsilon}(x) = \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} e^{ipx} \hat{F}_{\omega, \varepsilon}(p) \), with
\[
\hat{F}_{\omega, \varepsilon}(p) := \frac{\hat{\delta}_0(p) A_{\varepsilon}(p)}{D_{\omega}(p)}, \quad A_{\varepsilon}(p) := \frac{1}{2} \left( \frac{1}{1 - \tau \hat{\delta}_0(p)} + \varepsilon - \frac{1}{1 + \tau \hat{\delta}_0(p)} \right).
\]  
(C.30)
The solution of (C.28) and (C.29) decaying to zero at infinity, as one can easily check by substitution, is

\[
G_{R,\omega}^{(2)}(x, y) = Z e^{-\lambda_{\omega}[\Delta_{\omega}(x-y,0)]} g_{R,\omega}(x - y),
\]

\[
G_{R,\omega}^{(4)}(x, y, u, v) = e^{\lambda_{\omega}[\Delta_{\omega}(x-y,0) - \Delta_{\omega}(x-u,0) - \Delta_{\omega}(v-u,0) + \Delta_{\omega}(x-y,0) - \Delta_{\omega}(x-u,0)]} G_{R,\omega}^{(2)}(x, v) G_{R,\omega}^{(2)}(y, u),
\]  

(C.31)

where

\[
g_{R,\omega}(x) = \int_{\mathbb{R}^2} \frac{dk}{(2\pi)^2} \frac{e^{-ik(x-y)}}{(-i - \omega)k_1 + (-i + \omega)k_2},
\]

and

\[
\Delta_{\omega}(x, z) := \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} \frac{e^{ipz} - e^{ipz}}{D_\omega(p)} 
\]

(C.32)

By using the fact that, asymptotically for large \(|x|\),

\[
\Delta_{\omega}(x, 0) \sim -\frac{A_{\omega}(0)}{4\pi} \log|x|,
\]

(C.33)

we find from (C.27) and (C.31) that

\[
S_{R,\omega,\omega}^{(2,2)}(x, y) \sim (\text{const.}) |x - y|^{-2(1-\tau)/(1+\tau)},
\]

(C.34)

where we recall that \(\tau = -\lambda_{\omega}/(8\pi)\). This proves (6.15).

It then remains to for us to give a sketch of the proof of (C.28) and (C.29). Let us start with (C.28). The idea is to combine the Ward identities (C.24) with the so-called Schwinger–Dyson equation for the propagator, which reads

\[
\hat{G}_{R,\omega}^{(2)}(k) = \frac{Z}{D_\omega(k)} \left[ 1 + \frac{\lambda_{\omega}}{Z(1)} \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} \hat{\rho}_0(p) \hat{G}_{R,\omega,\omega}^{(2,1)}(k, p) \right].
\]

(C.35)

For an elementary proof of this identity, see [5, appendix A.1].

On the other hand, the two Ward identities (C.24) imply a second, independent, relation between \(\hat{G}_{R,\omega,\omega}^{(2,1)}(k, p)\) and the dressed propagator: in fact, by solving (C.24) for \(\hat{G}_{R,\omega,\omega}^{(2,1)}(k, p)\) we find

\[
\frac{Z}{Z(1)} \hat{D}_{\omega}(p) \hat{G}_{R,\omega,\omega}^{(2,1)}(k, p) = A_{\omega}(p) \{ \hat{G}_{R,\omega}^{(2)}(k) - \hat{G}_{R,\omega}^{(2)}(k + p) \}.
\]

(C.36)

By plugging this equation into (C.35), taking the Fourier transform, and using the fact that \(\int \hat{F}_{\omega,\omega}(p) dp = 0\), we get (C.28), as desired.

In order to prove (C.29) we proceed analogously. The required analog of the Ward identity (C.14) is obtained by deriving (C.12) w.r.t. \(\dot{\phi}_{x,\omega}^-, \dot{\phi}_{y,\omega}^- \phi_{x,\omega}^+, \phi_{y,\omega}^+, \) and \(\phi_{x,\omega}^+, \phi_{y,\omega}^+, \) then setting the external sources to zero, and finally taking the removed cut-offs limit. The result is

\[
[\delta_{\omega,-\omega}(\delta(x - z) - \delta(x - y)) + \delta_{\omega,-\omega}(\delta(x - v) - \delta(x - u))] G_{\omega}^{(4)}(y, u, v, z) - \frac{Z}{Z(1)} \hat{D}_{\omega}(x, y, u, v, z) \]

(C.37)
where
\[
G^{(4,1)}_{R,\omega}(x, y, u, v, z) := Z^{(1)} Z^4 \lim_{L, N, a \to \infty} \langle \rho^{(1)}_{x, \omega} \psi^+_{y, \omega} \psi^+_{u, -\omega} \psi^+_{v, -\omega} \psi^+_{z, \omega} \rangle_{L, N, a},
\]
\[
I^{(1)}_{\omega}(x, y, u, v, z) := Z^{(1)} Z^4 \lim_{L, N, a \to \infty} \langle \delta \mathcal{T}_\omega(x); \psi^-_{y, \omega} \psi^-_{u, -\omega} \psi^+_{v, -\omega} \psi^+_{z, \omega} \rangle_{L, N, a}.
\]

We now take the Fourier transform, with the conventions
\[
G^{(4,1)}_{R,\omega}(x, y, u, v, z) = \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{dk_1}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{dk_2}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{dq}{(2\pi)^2} \times e^{ipx - i(k_1+p)y - i(k_2+q)v + i(k_1+q)z} \hat{G}^{(4,1)}_{R,\omega}(p, k_1, k_2, q),
\]
\[
G^{(4)}_{R,\omega}(y, u, v, z) = \int_{\mathbb{R}^2} \frac{dk_1}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{dk_2}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{dq}{(2\pi)^2} \times e^{-ik_1y - ik_2u + ik_1q + i(k_1+q)z} \hat{G}^{(4)}_{R,\omega}(k_1, k_2, q),
\]
and similarly for \( I^{(1)}_{\omega} \). If we combine the two equations obtained from (C.37) by setting \( \omega = \omega \) and \( \omega = -\omega \), and we use the fact that the anomaly term \( \hat{I}^{(1)}_{\omega} \) has an expression completely analogous to (C.23), namely
\[
\hat{I}^{(1)}_{\omega}(p, k_1, k_2, q) = -\frac{\lambda_\infty}{8\pi} D_{\omega}(p) \hat{v}_0(p) \hat{G}^{(4,1)}_{R,\omega}(p, k_1, k_2, q), \tag{39}
\]
we get
\[
\frac{Z}{Z^{(1)}} D_{\omega}(p) \hat{G}^{(4,1)}_{R,\omega}(p, k_1, k_2, q) = A_-(p) \hat{G}^{(4)}_{R,\omega}(k_1, k_2, q) - \hat{G}^{(4)}_{R,\omega}(k_1 + p, k_2, q) + A_+(p) \hat{G}^{(4)}_{R,\omega}(k_1 + p, k_2 - p, q - p) - \hat{G}^{(4)}_{R,\omega}(k_1 + p, k_2, q - p)), \tag{40}
\]
which is the analog of (C.36).

In addition to this Ward identity, we need the analog of (C.35), that is, the Schwinger–Dyson equation for the four-point function, which reads
\[
\hat{G}^{(4)}_{R,\omega}(k_1, k_2, q) = -\frac{Z}{Z^{(1)}} D_{\omega}(k_1) \left[ (2\pi)^2 \delta(q) \hat{G}^{(2)}_{R,\omega}(k_2) + \frac{\lambda_\infty}{Z^{(1)}} \int_{\mathbb{R}^2} \frac{dp}{(2\pi)^2} \hat{v}_0(p) \hat{G}^{(4,1)}_{R,\omega}(p, k_1, k_2, q) \right]. \tag{41}
\]
If we now plug (40) into (41) we finally obtain (C.29), as desired.
