Abstract

Aim: The aim of present study was to determine seroprevalence of bluetongue virus (BTV) in Haryana state of India.

Materials and Methods: A total of 803 serum samples, 408 of cattle and 395 of buffalo origin, respectively, were collected from different villages of Haryana. Sampling was done randomly to obtain unbiased results. The samples were evaluated by a competitive enzyme-linked immunosorbent assay for the presence of BTV antibodies.

Results: Overall seroprevalence of BTV antibody in cattle and buffaloes for all 21 districts of Haryana state was found to be 75.49% and 92.91%, respectively. The prevalence of BTV in different agroclimatic zones ranged between 72-77% and 90-94% for cattle and buffalo, respectively. In buffaloes, the BTV seroprevalence was comparatively higher than in cattle.

Conclusion: The study showed that BTV is circulating in cattle and buffalo populations in the Northern part of India.

Keywords: bluetongue, bluetongue virus, buffalo, cattle, competitive enzyme-linked immunosorbent assay, Haryana, India, serology.

Introduction

Bluetongue (BT) is an arthropod-borne disease of wild and domestic animals caused by bluetongue virus (BTV) of genus Orbivirus in the Reoviridae family [1,2]. The disease is characterized by fever, facial edema, hemorrhages, and ulceration on the oral mucosa and coriniths. Cattle and buffaloes are sub-clinically affected and are carriers of BTV. Even though this true for many strains of the virus, however, during the European outbreak of BT caused by BTV-8 in 2006, the cattle were severely affected [3]. The clinical signs in BTV-8 affected sheep flocks and cattle herds in 2007 and 2006 were similar.

BTV is not contagious, and it is transmitted by Culicoides vector midges [4,5]. In India, the disease is endemic particularly in Southern states namely, Tamil Nadu, Karnataka, Kerala, and Andhra Pradesh. To date, 27 serotypes of this virus have been reported worldwide; however, there are further putative serotypes reported recently [6-10]. There is a low level of cross-protection among different serotypes, thus creating difficulties when designing of vaccines, vaccination strategies, and planning control measures [11]. Fifteen BTV serotypes have been isolated in India (BTV-1, -2, -3, -4, -5, -6, -8, -9, -10, -12, -16, -17, -18, -21, -23, and -24), eleven of these in the past decade, with serological evidence of presence of eight more (BTV-6, -7, -11, -13, -14, -15, -19, and -20) [12]. BT outbreaks result in an estimated 3 billion USD/annum losses across the globe, both directly and indirectly [13,14]. Although there are no precise figures for economic losses due to BT in India, a study published in 2009 assessed the economic losses due to important diseases of sheep in India between 1991 and 2005, and BT was found to cause more economic devastation than foot and mouth disease (FMD), peste des petits ruminants, sheep and goat pox, anthrax, fascioliasis/distomatosis, and enterotoxemia [15]. The greatest direct losses to farmers due to BT occurred in 2005, amounting to approximately 231 million rupees [16]. Direct losses are a result of mortality and decline in production of affected animals. Indirect losses are due to trade embargoes and animal movement restrictions [1].

Due to its huge economic importance, it is paramount to detect BTV infection both in endemic and...
BTV-free countries. Complement fixation test, agar gel immunodiffusion (AGID), and competitive enzyme-linked immunosorbent assay (c-ELISA) are the OIE recommended methods for BT testing for international trade [17]. Of these 3 tests, the c-ELISA has proven to be highly sensitive. It can be used to detect antibodies raised against all BTV serotypes [15]. The specificity of this test is due to the use of monoclonal anti-VP7 which can distinguish the BT serogroup from other orbivirus serogroups, for example, epizootic hemorrhagic disease virus (EHDV) [18-20]. It has been found that the diagnostic sensitivity and specificity of c-ELISA is 87.8% (85.10-91.10) and 98.2% (96.30-99.60), respectively [21]. Therefore, the antibody detecting VP7-based c-ELISA was employed in this study to determine the seroprevalence of BTV in Haryana state of India.

In India, a few studies have been conducted on seroprevalence of BT, but their results do not have much significance due to testing of less/small number of samples. This is the first substantive seroprevalence study of BT in Haryana state based on random sampling and testing of a large number of serum samples from cattle and buffaloes.

Materials and Methods

Ethical approval

Ethical approval from Institutional Animal Ethics Committee was not required as no part of research had been carried out in live laboratory or domestic animals.

Animals

The blood samples were collected from 803 animals (cattle and buffaloes) from 80 villages of 21 district of Haryana. The details of animals are given in Table-1.

Study area

Haryana is one of the northern states of India situated between 27° 37’ to 30° 35’ latitude and between 74° 28’ to 77° 36’ longitude and with an altitude between 700 and 3600 ft above sea level. Haryana is primarily an agricultural state. The general slope of the terrain is from north-east to south-west and west with an exception in the south in Bhiwani, Mahendragarh, Rewari, and Gurgaon districts where the slope is toward north. Most of the year, the climate of Haryana is very hot in summer (May to June) and markedly cold in winter (December and January) where as in between are the pleasant months of spring. The rainfall in the region is low and erratic except in parts of Karnal, Kurukshetra, and Ambala districts ranging from 300 mm in the southwest to 1100 mm in the northeast of the state. The samples were collected throughout the year.

Serum samples

Serum was separated from 5 ml of blood collected from cattle and buffaloes, which was stored at −20°C until further use. A total of 803 serum samples, 408 from cattle and 395 from buffaloes, were collected through RRC-FMD from 80 villages of Haryana in 2014. These blood samples were taken from animals in the field, by qualified veterinarians, as part of normal veterinary care and diagnostic testing procedures in the Haryana, India. The statistical model is described as follows.

Statistical model for random sampling and sample size determination

To conduct serosurveillance studies in Haryana state, a model was designed for random sampling using SPSS software. The number of samples to be tested was calculated as described below. Villages having cattle/buffalo population more than 200 were taken for statistical analysis. The prevalence of BT was considered as 50% with 95% confidence interval. Using these values, random sampling model was designed. The above values along with the animal population data as per 19th livestock census of 2012 for all villages in Haryana were used to obtain the number and name of villages for random sampling (http://pashudhanharyana.gov.in/html/pdf%20%&%20downloads/LC%202012/Districtwise%20Livestock%20Census%202012.pdf).

C-ELISA

The c-ELISA kits were procured from the Veterinary Medical Research and Development, USA. The ELISA was performed as per the manufacturer’s instructions. Briefly, 25 µl of neat serum, positive control, and negative control were added to antigen (VP7) pre-coated plates in duplicates and test samples in a single well. These plates were then firmly tapped 14 times on the long sides and incubated for 15 min at room temperature (RT). 25 µl of antibody peroxidase conjugate was then added to each well, tapped firmly, and further incubated for 15 min at RT. Plates were then washed 3 times using wash solution, and remaining sera was removed by striking the inverted plates 4 times on a clean paper towel. Thereafter, 50 µl of substrate was added, and plates were tapped firmly and incubated for 10 min at RT. 50 µl of stop solution was added, and immediately, the plates were read in a microplate spectrophotometer at 620 nm. The plates were deemed pass if the mean of negative control optical density (OD) was 0.300-2.00 and mean of the positive control was <50% of the mean of negative control. Test samples were considered positive if they produce OD <50% of the mean of negative controls and negative if they produce OD >50% of the mean of negative controls.

Results

Based on the random sampling mode, a total of 803 serum samples, 408 from cattle and 395 from buffaloes, were collected from 80 different villages of 21 districts of Haryana (Figure-1). In Haryana, the domestic animal population is dominated by buffaloes (6.08 million - 69%) and cattle (1.80 million

Veterinary World, EISSN: 2231-0916 1465

Available at www.veterinaryworld.org/Vol.10/December-2017/8.pdf
- 20.50%), whereas sheep (0.36 million - 4.11%), goats (0.36 million - 4.19%), pigs only 1.44%, and remaining 0.76% constituted by other species as shown in pie chart (Figure-2).

Different districts of Haryana are divided into two agroclimatic zones, i.e. eastern and western zones as shown in Haryana map Figure-1 and Table-2. The prevalence of BTV in different agroclimatic zones ranged between 72-77% (Table-3) and 90-94% (Table-4) for cattle and buffalo, respectively. The prevalence of BTV antibodies in cattle and buffalo per district is shown in Table-5.

Overall seroprevalence of BTV antibody in cattle and buffaloes for all 21 districts of Haryana state was found to be 75.49% and 92.91%, respectively. District-wise seroprevalence in cattle was observed as follows: Gurgaon (100%), Mahendragarh (100%), Palwal (100%), Rohtak (100%), Sonepat (95%), Bhiwani (90%), Karnal (89.47%), Jind (85%), Mewat (85%), Faridabad (80%), Panipat, Rewari, Kurukshetra, and Fatehabad (65-70%), Hisar and Yamunanagar (53-58%), Sirsa (45%), Ambala (35%), and Kaithal (23%), respectively.

In buffaloes of Haryana, the BTV seroprevalence was comparatively higher than in cattle, with the districts of Gurgaon, Karnal, Mahendragarh, Mewat, Palwal, Panchkula, Panipat, Rohtak, and Yamunanagar showing 100% seropositivity. Ambala, Bhiwani, Jhajjar, Jind, and Sonepat had seroprevalences of 95%. Rewari was 93% seropositive, while

Faridabad, Fatehabad, and Sirsa each had seroprevalence of 80%. Kaithal and Kurukshetra were 60% and 50% seropositive, respectively.

**Discussion**

BT, an arthropod-borne viral disease, mainly affects sheep and wild ruminants. Among all susceptible vertebrates, sheep are the main hosts [22]. Clinical signs mainly involve fever, nasal discharge, frothy salivation, excoriation of oral mucosa, and laminitis [23]. BTV viral genome is mainly surrounded by two major structural proteins such as VP3 and VP7 and three minor structural proteins such as VP1, VP4, and VP6. This in turn is surrounded by outer capsid containing two structural proteins VP2 and VP5. The VP7 and VP3 polypeptides are predominant and constitute more than 50% of the total BTV protein structure. The VP7 antigen has been found to be a highly conserved group-specific antigen [24].

Diagnosis of exposure to BTV mainly relies on detecting antibodies to a group-specific antigen. The AGID test is the most widely used assay for this purpose [25]. Although AGID is simple and rapid to perform, it is insensitive and gives cross-reactivity with other orbiviruses like EHDV. The use of monoclonal antibodies against BTV group-specific protein VP7 in c-ELISA can overcome this problem [26]. The serological response in BTV infection appears usually
7-14 days post-infection, and antibodies are generally long-lasting.

In India, the occurrence of BT between different parts of the country is dependent on the rainfall, with maximum number of outbreaks occurring during the North-East monsoon, followed by South-West monsoon [27]. In the study presented here, seroprevalence of BTV in cattle and buffalo was found to be 75.29% and 93.41%, respectively. Buffaloes exhibited higher seroprevalence than cattle. Serological evidence of BTV infection in local and exotic cattle breeds and buffaloes has been reported earlier from several states of India [28,29], indicating inapparent BTV infection in both cattle and buffaloes, although there are no reports of clinical BT in these animals in India.

A BT seroprevalence of 58.33% was observed in buffaloes in Gujarat [30]. In earlier studies by Raut et al. [31], a high seroprevalence was observed in cattle and buffalo of Maharashtra with 89.80% and 80%, respectively. However, in the southern state of India in Kerala, Arun et al. [32] reported that the percentage positivity in cattle was 6.9% which was below the overall prevalence of the disease previously reported in Kerala. Joarder et al. [33] screened a total of 313 animal serum samples (sheep - 68, goat - 195, and cattle - 50). 58.82% of sheep, 31.79% of goat, and 70.00% of cattle serum samples were found positive for the presence of antibodies for BTV. The prevalence of anti-BT antibodies in different agroclimatic zones ranged between 31 and 50%. This study revealed high seroprevalence of BT in cattle, sheep, and goats in Assam, north-eastern state of India. Bhagat et al. [34] tested a total of 510 goat serum samples from different part of Gujarat (western part of India). Among the samples tested, 292 (57.25%), 202 (39.61%), and 135 (26.47%) samples were found seropositive by c-ELISA, i-ELISA, and AGID test, respectively. Tigga et al. [35] studied serum samples of different small ruminants from Jharkhand (an eastern state of India) for the presence of BTV antibodies. Of the 480 serum samples tested, 83/190 (43.68%) sheep, 91/210

**Table-5:** District-wise seroprevalence of BTV in cattle and buffaloes of Haryana state.

| Districts     | Cattle | Buffalo |
|---------------|--------|---------|
| Ambala        | 35.00  | 95.00   |
| Bhiwani       | 90.00  | 95.00   |
| Faridabad     | 80.00  | 80.00   |
| Fatehabad     | 70.00  | 80.00   |
| Gurgaon       | 100.00 | 100.00  |
| Hisar         | 53.30  | 91.66   |
| Jhajjar       | 90.00  | 95.00   |
| Jind          | 85.00  | 95.00   |
| Kaithal       | 23.30  | 60.00   |
| Karnal        | 89.47  | 100.00  |
| Kurukshetra   | 66.60  | 50.00   |
| Mahendragarh  | 100.00 | 100.00  |
| Mewat         | 85.00  | 100.00  |
| Palwal        | 100.00 | 100.00  |
| Panchkula     | 90.00  | 100.00  |
| Panipat       | 65.00  | 100.00  |
| Rohtak        | 70.00  | 93.33   |
| Sirsa         | 45.00  | 80.00   |
| Sonepat       | 95.00  | 95.00   |
| Yamunanagar   | 58.33  | 100.00  |

**Figure-2:** Distribution of livestock in Haryana. Adapted from 19th livestock census 2012, chapter 14, Haryana.
(43.33%) goats, and 46/80 (57.50%) cattle were found positive. The results of a study by Tigga et al. [35] showed slightly higher seroprevalence, although not significantly at two degrees of freedom (5%), in cattle than sheep and goats in different agroclimatic zones of Jharkhand. Sharma et al. [36] estimated the seroprevalence of antibodies to BTV among domestic ruminants of Grenada. They tested 928 sera samples (cattle - 133, goat – 314, and sheep - 481) using c-ELISA. They found that the overall BTV seroprevalence was 78.4% (95% confidence interval [CI] ± 2.65). The seropositivity of ovine, caprine, and bovine was found to be 71.7%, (95% CI, 67.67-75.73%), 80.2% (95% CI, 75.79-84.61%), and 98.5% (95% CI, 96.43-100.57%), respectively.

The high seroprevalence of BTV in cattle and buffalo population of Haryana state showed their prior exposure to BTV. The free movement of animals from the adjoining states of Rajasthan and intermixing with other animals for grazing (favoring two-way transmission of virus) along with an increase in the number of adult Culicoides oxystoma (the north Indian vector for BTV) during the rainy season overlaps with the spread of BTV in northern India. Moreover, proper surveillance program based on sero-monitoring can help forecast the possible future outbreaks. Attempts of isolation of the virus from the blood of the seropositive animals of Haryana and serotyping of the virus were not successful. There is no current BTV vaccination program in North India. Future, owing to the presence of large number of non-cross-protecting BTV serotypes circulating in the area, the control of disease in the region is difficult to achieve.

However, recent developments of inactivated or subunit vaccines may in the future help to control the disease in the state.

Conclusion

Overall seroprevalence of BTV specific antibody in cattle and buffaloes for all 21 districts of Haryana state was found to be 75.49% and 92.91%, respectively. The prevalence of BTV in different agroclimatic zones ranged between 72-77% and 90-94% for cattle and buffalo, respectively. In buffaloes, the BTV seroprevalence was detected to be comparatively higher than in cattle. Conclusively, the study showed the BTV circulation is quite wide spread in cattle and buffalo populations in the Northern part of India.

Authors’ Contributions

SM, AT, and DC: Analyzed the data. SM, AT, DC, and AD: Drafted the manuscript. SM, NK, NSM, VK, and NB: Contacted the officials of State AH department and collection of samples. SM, NK, AT, NSM, and AK: Provided reagents and materials. AT, KB, AD, and NB: Conducted the experiments. SM, DC, AD, AK, NK, and NSM: Proof read the manuscript and provided the guidance. All authors read and approved the final manuscript.

Acknowledgments

The farmers, veterinarians, and personnel of the Department of Animal Biotechnology are acknowledged for their help in the study. We acknowledge funding support from DBT Bio-CARE grant (BT/Bio-CARE/04/261/2011-12), BBSC-DBT (BT/IND-UK/FADH/46/SM/2013) and Rashtriya Krishi Vikas Yojana (RKVY) from the Government of India.

Competing Interests

The authors declare that they have no competing interests.
