Abstract. We explore some possibilities for obtaining useful dilatons for AdS/QCD models. As a guideline, we consider dilatons that on the one hand reproduce the mesonic spectrum, and that on the other hand allow us a correct implementation of chiral symmetry breaking in AdS/QCD models. We discuss two procedures: one is based on supersymmetric quantum mechanics techniques and the other considers the interpolation between some limits on dilatons.

1. Introduction
The holographic approach to QCD has attracted a great deal of interest, primarily in two directions, i.e., top-down and bottom-up approaches [1]-[4]. Top-down approaches start from string theory and, after taking low-energy limits and compacting extra dimensions, attempt to obtain a theory close to QCD. In the bottom-up approach, well-known QCD properties are used as guidelines to build models in a gravity frame with asymptotically anti-de Sitter (AdS) spaces, thereby obtaining models denoted as AdS/QCD.

In the context of bottom-up models, several hadron properties can be easily calculated (see, e.g., [5]-[17]). The first version of an AdS/QCD model is known as hard wall (HW) [18, 19], where conformal invariance was broken by introducing a hard cut-off in a holographic coordinate; therefore, a field dual to hadrons cannot propagate in all space. The main problem with HW models is that, because the relationship between $M^2$ and $J$ it is not linear, they do not reproduce Regge behavior. To improve this aspect, the soft wall (SW) model was proposed [20], where conformal invariance is broken by using a dilaton field. This scalar field allows us to introduce a soft cut-off along the holographic coordinate.

The most common dilaton used is quadratic in a holographic coordinate with AdS metric, and although in this case it is possible to obtain a spectrum with Regge behavior in the mesonic sector, this model is not free of problems. This situation has motivated several authors to search for improvements in this kind of model (see, e.g., [21, 22, 23] and references therein).

In AdS/QCD models the spectrum is calculated using a Schrödinger-type equation of motion; therefore, using techniques that can achieve strictly isospectral potentials could be very useful when exploring different alternatives for dilatons or metrics [24]. This offers us an opportunity to go beyond the typical choice for formulating AdS/QCD models. In this work we focus on different dilatons, but as was discussed on [24] similar ideas can be used to study different metrics.

There are several methods for obtaining a family of strictly isospectral potentials for Schrödinger equations (see, e.g.,[25]-[29]). In this work we use one developed in context of supersymmetric quantum mechanics (SUSY QM) [29]. By using SUSY QM techniques we can
explore dilatons (and/or metrics) that reproduce the same mesonic spectrum as in the usual models that consider quadratic dilaton and AdS metrics.

Applications of SUSY QM to AdS/QCD models have been considered previously [30]-[33], though in a different way: these authors consider transformations that produce potentials which are not strictly isospectrals, i.e., in one state the original potential and its supersymmetric partner differ. By using these transforms in they have shown that conformal invariance in the equation that describes bound states of quarks in light front holography produce interesting superconformal relationships that connect mesonic spectrum with a spectrum of baryons in light and heavy-light sectors.

The procedure propose by us in [24], considers first obtain a Schrödinger-type equation, and from this we derive a family of strictly isospectral potentials, and associated with these new potentials it is possible to extract a family of metrics and/or dilatons to AdS/QCD models (Here we focus on dilatons only). For the sake of simplicity, in this work we studied the family of dilatons related to Schrödinger equations that describe scalar glueballs in conventional SW models (i.e., AdS metric and quadratic dilaton) [34, 35, 17]. Because the mass of the gravity mode dual to scalar glueballs in AdS is zero, we obtained simplified equations.

Through the use of SUSY QM techniques, we suppose a family of strictly isospectral potential with a holographical coordinate $z$ that has the same behaviour at small and high values. This means, for example, if we consider as original potential one associated with AdS metric with quadratic dilaton, each dilaton in the family with AdS metric will have $\phi(z \to 0) = \kappa^2 z^2$ and $\phi(z \to \infty) = \kappa_\infty^2 z^2$. By construction, each dilaton in this family produces the same spectrum for scalar glueballs, but unfortunately these dilatons have the same problem as quadratic ones at the moment of building AdS/QCD models with chiral symmetry breaking. The problem with chiral symmetry breaking in AdS/QCD models has motivated the study of some modifications to these models [36, 37, 38, 39, 40].

To solve the problem associated with the correct implementation of chiral symmetry breaking in SW models, some authors have considered dilatons that correspond to an interpolation between $\phi(z \to 0) = \kappa_0^2 z^2$ and $\phi(z \to \infty) = \kappa_\infty^2 z^2$, where $\kappa_0^2 \neq \kappa_\infty^2$ [37, 41, 42]; dilatons that interpolate between these limits can be obtained by introducing small changes in the isospectral potential calculated with SUSY QM transforms.

This article contains six sections. In Sec. II we briefly show how to obtain the spectrum for scalar hadrons with SW models that consider an asymptotically AdS metric and an arbitrary $z$-dependent dilaton. In Sec. III we discuss the method we use to obtain a family of strictly isospectral potentials in the context of SUSY QM, and we explain how we used this to obtain a differential equation that allowed us to extract a family of dilatons. As an example, we present in detail the scalar glueball case. In Sec. IV we discuss the main problem in AdS/QCD models with chiral symmetry breaking. In Sec. V we present the possibility for using SUSY QM techniques to obtain families of dilatons consistent with the guidelines proposed; at the end of that section, we introduce a brief discussion about the interpolation functions for dilatons. Finally, in Sec. VI we present our conclusions and some future perspectives for additional work in this area.

2. Scalar fields

We consider a SW model, where action for scalar fields in spaces with 5D with dilaton is [36, 43, 44, 45]

$$S = - \int d^5x \sqrt{-g} e^{-\phi(z)} \frac{1}{2} [g^{MN} \partial_M \Phi \partial_N \Phi + m_5^2 \Phi^2], \quad (1)$$

with $M, N = 0, 1, 2, 3, z$, where $z$ is a holographic coordinate, $\phi(z)$ is a scalar dilaton field (used to break the conformal invariance in SW models) and $m_5$ is the mass of AdS modes along bulk
dilaton are in agreement with Regge trajectories because $M^2 = \Delta(\Delta - 4)$.

The metric considered was
\[ ds^2 = a^2(z)\eta_{MN}dx^Mdx^N, \]
where $\eta_{MN} = \text{diag}(-1, +1, +1, +1)$, and $a^2(z)$ is a warp factor; therefore, in general we can consider AdS spaces asymptotically.

We considered scalar modes according to
\[ \Phi(x) = e^{-iP\cdot x}f(z), \]
where $P$ and $\mathcal{X}$ correspond to momentum and position in boundary 4D and $P^2 = M^2$, where $M$ is the mass of hadron studied with this model.

Starting from equation of motion obtained from (1), and by using (3), it was possible to get an equation to $f(z)$
\[ -f''(z) + \left(\phi'(z) - 3\frac{a'(z)}{a(z)}\right)f'(z) + a^2(z)m^2_\Phi f(z) = M^2 f(z), \]
which, by transforming
\[ f(z) = \exp\left[\frac{1}{2}(\phi(z) - 3\ln a(z))\right]\psi(z), \]
gives rise to a Schrödinger-type equation of the form
\[ -\partial^2_z + V(z)\psi(z) = M^2 \psi(z), \]
where $V(z)$ is the potential
\[ V(z) = m^2_\Phi a^2(z) + \frac{3}{4}\left(\frac{a'(z)}{a(z)}\right)^2 - \frac{3}{2}\left(\frac{a'(z)}{a(z)}\right)\phi'(z) + \frac{1}{4}\phi''(z) + \frac{3}{2}\frac{a''(z)}{a(z)} - \frac{1}{2}\phi''(z). \]

Through the use of $a(z) = R/z$ (where $R$ is the AdS radius) and $\phi(z) = \kappa^2 z^2$, the conventional AdS/QCD model was obtained [36, 43, 44], which considers an AdS metric and a quadratic dilaton, and in this case, the potential is
\[ V(z) = \frac{1}{z^2}\left(\frac{15}{4} + m^2_\Phi R^2\right) + z^2 \kappa^4 + 2\kappa^2. \]

For this case, a solution to the eigenvalue problem (6) is
\[ \psi(z) = N_n \exp^{-\frac{1}{2}z^2\kappa^2}z^{\left(\frac{1}{2} + \sqrt{4 + m^2_\Phi R^2}\right)/2}L_n^{4 + m^2_\Phi R^2}(z^2 \kappa^2), \]
where $N_n$ is a normalization constant, that for the special case $n = 0$ (that will be used later), is
\[ N_0 = \frac{2\kappa^2(1 + \sqrt{4 + m^2_\Phi R^2})}{\Gamma(1 + \sqrt{4 + m^2_\Phi R^2})}. \]

The mass spectrum is given by
\[ M^2_n = 4\kappa^2\left(n + \frac{1}{2}\sqrt{4 + m^2_\Phi R^2} + 1\right). \]

As can be seen in the previous expression, SW models with an AdS metric and quadratic dilaton are in agreement with Regge trajectories because $M^2_n$ vs $n$ is linear.
3. Family of isospectral dilatons considering SUSY QM techniques

As we saw in the case of SW models, if we start with an AdS metric and a quadratic dilaton it is possible to obtain a Schrödinger-type equation associated with different hadrons on the AdS side. Although not a common practice, using the reverse (i.e., starting from a given potential) it is possible to extract a metric and a dilaton that reproduce this potential. This is the base of procedure presented in [24], and discussed in this section.

For Schrödinger-type equations, there are several procedures that make it possible to obtain a family of strictly isospectral potentials associated with a given potential [25, 26, 27, 28, 29]. From among the different isospectral transformations, we used a procedure discussed in [29], that considers SUSY QM to obtain a family of strictly isospectral potentials depending on a parameter.

According to [29], two potentials $V_1$ and $\hat{V}_1$ are strictly isospectral if

$$\hat{V}_1(z) = V_1(z) - 2 \frac{d^2}{dz^2} \ln[I(z) + \lambda].$$

In this case, $V_1(z)$ is the original potential (8), $\lambda$ is an arbitrary parameter and the function $I(z)$, for coordinate between zero and infinity, is given by

$$I(z) = \int_0^z \psi_1^2(z')dz',$$

where $\psi_1$ corresponds to the ground state of $V_1$, in our case is given by (9) with $n = 0$; using $R = 1$ we obtained

$$I(z) = 1 - \frac{\Gamma(1 + \sqrt{4 + m_5^2, z^2 \kappa^2})}{\Gamma(1 + \sqrt{4 + m_5^2})}.$$  \hspace{1cm} (13)

Figure (1) shows several strictly isospectral potential that appeared from (12), starting with $V_1(z)$ given by (8) for scalar glueballs ($m_5 = 0$); it is possible to compare different potentials in this family in relation to the original one, and note also that changes in potentials are produced in a region close to the origin in $z$ and depends on $\lambda$. At higher values of $\lambda$, changes in family...
 potentials are less, so when \( \lambda \to \infty \) we recover the original potential. Again, all potentials in Fig. 1 produce the same spectrum for scalar glueballs, which in this case it is Regge-like.

Each member of this family was obtained by using (12) which could be considered as having been generated for a new metric and/or a new dilaton. For this reason we could match (12) and (7) and get

\[
V_1(z) - 2 \frac{d^2}{dz^2} \ln[I(z) + \lambda] = m_5^2 a^2(z) + \frac{3}{4} \left( \frac{a'(z)}{a(z)} \right)^2 \phi'(z) + \frac{1}{4} \phi'^2(z) + \frac{3}{2} \frac{a''(z)}{a(z)} - \frac{1}{2} \phi''(z) - m^2_5 R^2 z^2 - \frac{3 \phi'(z)}{2z} + \frac{1}{4} \phi'^2(z) - \frac{1}{2} \phi''(z).
\]

(14)

Figure (2) shows several dilatons of family obtained solving (15).

It is important to verify that this procedure produces potentials with the same behaviour at low and high \( z \) as the original one. However, as we show in next section, this must be changed in order to obtain dilatons or metrics appropriated in AdS/QCD models. This must be considered when using boundary conditions to solve the differential equations suggested in this section, and it obligates us to introduce modifications on them.

4. Improvements in AdS/QCD models with chiral symmetry breaking

Although the spectrum in bottom-up models with an AdS metric and quadratic dilaton is well reproduced in the mesonic sector [30, 31, 32, 33, 46, 47], the incorporation of chiral symmetry breaking in this approach is far from QCD and needs improvements. This occurs because the scalar field in the bulk is dual to bilinear operator \( q \bar{q} \), whose vacuum expectation value (VEV) —which is responsible for chiral symmetry breaking in this model— does not allow its explicit and spontaneous breaking in an independent and simultaneous way [36, 37, 38, 39, 40]. The origin of this problem can be found in the solution of the VEV equation, which produces a finite action at the limit \( z \to \infty \), given by.
\( v(z) \sim m_q z U(1/2, 0, z^2), \) 

where \( U(a, b, z) \) is a hypergeometric confluent function. According to the AdS/QCD dictionary established in [18], the VEV limit \( z \to 0 \) must be

\( v(z) \sim \alpha z + \beta z^3. \) 

(17)

In these models, quark mass \( m_q \) and chiral condensate \( \sigma \) are related with a constant that appears in (17) through [18]

\[ m_q = \frac{\alpha R}{\zeta} \quad \text{and} \quad \sigma = \beta R \zeta, \] 

(18)

where \( \zeta \) is a normalization parameter introduced in [48].

According to Gell-Mann–Oakes–Renner (GMOR) relationship, \( m_q \) and \( \sigma \) are related by \( m_q^2 f_π^2 = 2m_q \sigma \): if we expand (16) to small values of the holographic coordinate, we get \( \alpha \sim m_q \) and \( \beta \sim \sigma \sim m_q \). This means that when quark mass is zero in this model then the chiral condensate is also zero, and this is not in agreement with GMOR.

The literature has some alternatives to solve this problem. For example, a negative quadratic dilaton could be a possible alternative [49], but it predicts an extra massless mode that are not observed [50]. It was recently suggested [41] that an interpolation between two quadratic dilatons, one negative to small \( z \) and another positive to high \( z \), could solve the problem without spurious modes that appear only with a negative dilaton. Another way to improve this model was studied in [37], where authors considered adding a quartic term in the scalar potential; in this case, they obtained

\[ \phi' = \frac{1}{a^3 v'} \left[ \partial_z (a^3 v') - a^5 \left( m_X^2 v - \frac{\kappa}{2} v^3 \right) \right] \] 

(19)

which corresponds to an equation that relates the dilaton field \( \phi(z) \), the warp factor in metric \( a(z) \), VEV \( v(z) \) and a constant \( \kappa \) introduced in quartic term in action.

We can properly incorporate chiral symmetry breaking in soft-wall models by using (19) with an AdS metric \( [a(z) = R/z] \) and

\[ v(z) = \frac{z}{R} (A + B \tanh C z^2), \] 

(20)

which is an interpolation between the limits to small and high values in \( z \) for VEV. In this case dilaton satisfies

\[ \phi(z \to 0) = \kappa_0^2 z^2, \] 

(21)

\[ \phi(z \to \infty) = \kappa_\infty^2 z^2, \] 

(22)

where \( \kappa_0^2 = -\kappa_\infty^2 \) in [41] and \( \kappa_0^2 \neq \kappa_\infty^2 \) in [37]. We notice that, without details, which dilatons corresponding to interpolations between limit (21) and (22) can, according to some authors, improve other facts in the SW model (e.g., [51]).

5. Family of dilatons for AdS/QCD models using SUSY QM techniques

Dilatons in agreement with (21) and (22) cannot be obtained from (15), because the original potential and the strictly isospectral potential has the same behaviour at low and high \( z \) values; i.e., dilatons in family found with (15) have \( \phi(z \to 0) = \phi(z \to \infty) = \kappa^2 z^2 \). However, it is possible to introduce small changes to (15) in order to obtain dilatons in agreement with (21)
Figure 3. Dilatons for different values of $\delta$, $p = \text{even}$, $\kappa = 428\text{ MeV}$, $m_5 = 0$ and $\lambda = 0.1$ and (22). To achieve this, we added a new term in (15) that slightly modifies the behavior at small $z$.

We have two possible locations to introduce the change: on the right or left side in (15). Thus, instead of (15) we suggest:

$$\frac{1}{z^2} \left( \frac{15}{4} + m_5^2 \right) e^{-\delta z^2} + z^2 \kappa^4 + 2\kappa^2 - 2 \frac{d^2}{dz^2} \ln[I(z) + \lambda] = \frac{1}{z^2} \left( \frac{15}{4} + m_5^2 \right) e^{\delta z^2} + \frac{3\phi'(z)}{2z} + \frac{1}{4} \phi''(z) - \frac{\phi''(z)}{2}$$

or

$$\frac{1}{z^2} \left( \frac{15}{4} + m_5^2 \right) e^{-\delta z^2} + z^2 \kappa^4 + 2\kappa^2 - 2 \frac{d^2}{dz^2} \ln[I(z) + \lambda] = \frac{1}{z^2} \left( \frac{15}{4} + m_5^2 \right) e^{\delta z^2} + \frac{3\phi'(z)}{2z} + \frac{1}{4} \phi''(z) - \frac{\phi''(z)}{2}.$$

Notice that both equations can be summarized in

$$(-1)^p [e^{-\delta z^2} - 1] \frac{1}{z^2} \left( \frac{15}{4} + m_5^2 \right) + z^2 \kappa^4 + 2\kappa^2 - 2 \frac{d^2}{dz^2} \ln[I(z) + \lambda] = \frac{3\phi'(z)}{2z} + \frac{1}{4} \phi''(z) - \frac{\phi''(z)}{2},$$

where $\delta$ and $p$ are two parameters that modify the behavior of $\phi(z)$ at low $z$.

In Figs. 3 and 4 it is possible to see how $\delta$ modifies the magnitude of $\phi(z \to 0)$, and by using even or odd $p$ values it was possible to choose the sign of $\phi(0)$ according to (23) or (24). Increasing $\delta$ produces differences between the spectrum calculated with quadratic dilaton and the one obtained from (23), (24) or (25). This constrains us to use small values for $\delta$ if we wish to obtain a dilaton that produces a spectrum very close to the original one. The behavior of the dilaton obtained in both extensions is $\phi \to C \pm \kappa_0^2 z^2$, with $C$ a constant.

It is worth noting in relation to implementation of chiral symmetry breaking in AdS/QCD models that the constant term is not important, and it can be dropped to calculate other quantities. In addition, whether the change suggested was implemented according to (23) or (24) determines if $\kappa_0 < \kappa_\infty$ or $\kappa_0 > \kappa_\infty$.

An alternative procedure to built dilatons or metrics could be to consider interpolation functions between known limits. For example, for dilatons in models with AdS metrics it is possible to consider (21) and (22) as known limits, and in this case a possible dilaton could be

\begin{align*}
\text{Quadratic:} & \quad \delta = 0 \\
\delta = 0.1 & \\
\delta = 1 & \\
\delta = 10 &
\end{align*}
In this case, numerical calculation shows that this interpolation function produces a potential with Regge behaviour in a mass spectrum calculated with (6).

6. Summary and conclusions
In this work we discuss the ideas introduced in [24] to get families of dilatons useful for AdS / QCD models.

The main method discussed is based on SUSY QM techniques. This ensures that dilatons obtained with this procedure produce a proper mesonic spectrum. When we include as an additional condition the correct chiral symmetry breaking implementation, we found that in general this is not possible; however, introducing small changes in equations opens a possibility for obtaining dilatons that works in AdS spaces.

Another alternative studied considers dilatons that correspond to interpolating functions between two limits. In our case we consider limits when \( z \rightarrow 0 \) and \( z \rightarrow \infty \), and following Ref. [37], the limits suggested in (21) and (22) for dilatons.

In our opinion, dilatons presented here, or other that could be obtained through the procedures discussed in this paper, could be interestingly used to calculate hadronic properties in other uses of AdS/QCD models. These possibilities will be explored in future work.
