WEAK HOPF ALGEBRAS AND QUANTUM GROUPOIDS

PETER SCHAUENBURG

ABSTRACT. We give a detailed comparison between the notion of a weak Hopf algebra (also called a quantum groupoid by Nikshych and Vainerman), and that of a $\times_R$-bialgebra due to Takeuchi (and also called a bialgebroid or quantum (semi)groupoid by Lu and Xu). A weak bialgebra is the same thing as a $\times_R$-bialgebra in which $R$ is Frobenius-separable. We extend the comparison to cover module and comodule theory, duality, and the question when a bialgebroid should be called a Hopf algebroid.

1. Introduction

Quantum groupoids (or Hopf algebroids) are to groupoids what quantum groups (or Hopf algebras) are to groups: A Hopf algebroid is the noncommutative analog of the function algebra on a groupoid. A groupoid is a small category, and has a set of morphisms and a set of objects (in other terminology arrows and vertices). Thus the definition of a quantum groupoid should involve two algebras, one of which (say $H$) plays the role of the function algebra on the quantum space of morphisms, and the other (say $R$) the role of the function algebra on the quantum space of objects. Since there is a source and target assigned to each arrow, one should also expect (in the reversed direction) two maps from $R$ to $H$ to be part of the structure, while composition in the groupoid, a partially defined map on the product, should correspond to a comultiplication into a suitably defined tensor product of $H$ with itself.

In this note we will compare in detail two notions of quantum (semi)groupoids: The $\times_R$-bialgebras defined by Takeuchi [21], and the weak bialgebras defined by Böhm and Szlachányi [2]. Thus we shall, as it were, provide reference [NS] in [6]; while my joint paper with Florian Nill is announced there optimistically as a preprint to appear shortly, in reality it was never finished. The main result is as follows: A weak bialgebra is the same thing as a $\times_R$-bialgebra in which the algebra $R$ is Frobenius-separable.

The $\times_R$-bialgebras defined by Takeuchi [21], following work of Sweedler [20], are the first quantum (semi)groupoids appearing in the literature. One should note, though, that Takeuchi did not consider the analogy with groupoids at all, whereas this was the key motivation for the definitions of Lu [11] and Xu [22], which turn out to be equivalent to Takeuchi’s, mostly by a translation of notations, though some care has to be taken about the somewhat different definitions of counits. See the paper of Brzeziński and Militaru [4] for details.

Weak Hopf algebras were defined by Böhm and Szlachányi [2], see also the recent survey [15] by Nikshych and Vainerman and the literature cited there. A weak bialgebra $H$ is a coalgebra and algebra such that the comultiplication is multiplicative, but does not preserve the unit; dually the multiplication is not counital. These two requirements are replaced by certain weakened versions. In this definition there is
in the beginning no auxiliary algebra \( R \) playing the role of the function algebra on the set of vertices, but rather two anti-isomorphic “source and target counital subalgebras” are constructed from the axioms.

A special case of weak bialgebras, called face algebras, had been defined earlier by Hayashi [7, 8]. A face algebra turns out to be precisely the special case of a weak bialgebra in which the, say target, counital subalgebra is commutative. In [18] we have shown that a face algebra is precisely the special case of a \( \times_R \)-bialgebra in which the algebra \( R \) is commutative and separable.

It turns out that one can show by essentially the same calculations that a weak bialgebra is precisely the special case of a \( \times_R \)-bialgebra in which \( R \) is Frobenius-separable. A major difference is that Hayashi’s face algebras involve a commutative separable base algebra by definition, while one has to show that the target counital subalgebra of a weak bialgebra is Frobenius-separable.

The fact that any weak Hopf algebra is a \( \times_R \)-bialgebra (in fact a Hopf algebroid in the sense of Lu) has meanwhile been shown by Etingof and Nikshych [5, Prop.2.3.1], who also show that the target counital subalgebra is separable (note however that the formulas between (10) and (11) there seem to claim that the Frobenius automorphism is always trivial, which is not the case). This covers a large part of Theorem 5.1. However, the antipode is used in [5], while it is not assumed to exist in Theorem 5.1. On the other hand the part of the antipode relevant for the proof (its restrictions to the source and target counital subalgebras) is present in any weak bialgebra, even if it does not possess an antipode: this was proved by Nill [16] along with the fact that the counital subalgebras are Frobenius-separable.

After providing some definitions in Sections 2 and 3, we start the real work in Section 4 by proving some basic facts about weak bialgebras, notably that the counital subalgebra of a weak bialgebra is Frobenius-separable. As we acknowledged already, this (and all the facts proved in Section 4) can be found in the literature. However, Etingof and Nikshych [5] use antipodes, while Nill’s paper [16] consistently uses the assumption that the weak bialgebra in question is finite dimensional. The same general assumption is used in many places in [1]. Instead of examining the proofs in each situation to convince the reader that the extra assumptions are not necessary, it seemed easier and more useful to develop the basic facts that we need from scratch.

In Section 5 we prove that any weak bialgebra \( H \) is a \( \times_R \)-bialgebra (in fact a Hopf algebroid in the sense of Lu) has meanwhile been shown by Etingof and Nikshych [5, Prop.2.3.1] if \( H \) is a weak Hopf algebra, and conversely, that any \( \times_R \)-bialgebra with Frobenius-separable \( R \) is a weak bialgebra.

In Section 6 we address the question when a weak bialgebra is a weak Hopf algebra. We show in Theorem 6.1 that a weak Hopf algebra can be characterized as a weak bialgebra \( H \) for which a certain canonical map \( H \otimes_H H \to \Delta(1)(H \otimes H) \) is a bijection; this is analogous to a well-known characterization of ordinary Hopf algebras. (We should note that certain identities for antipodes useful for proving one of the implications in Theorem 6.1 can be found in [1], again under different assumptions). This also proves that a weak bialgebra is a weak Hopf algebra if and only if the associated \( \times_R \)-bialgebra is a \( \times_R \)-Hopf algebra in the sense of the definition we have given in [19]. One should note that this is in general rather different from the definition of a Hopf algebroid by Lu, which involves an antipodal anti-algebra map and a certain splitting of the epimorphism \( H \otimes H \to H \otimes_R H \).

Our definition by bijectivity of a canonical map has the advantage of having a canonical characterization in terms of properties of the module category of \( H \).
In Section 7 we show that the correspondence between weak bialgebras and $\times_R$-bialgebras is compatible with taking duals (in the finite-dimensional case), and with taking the respective comodule categories.

2. $\times_R$-BIALGEBRAS

In this section we will recall the necessary definitions and notations on $\times_R$-bialgebras. For more details we refer to [20, 21, 17].

Throughout the paper, $k$ denotes a base field. Modules, algebras, unadorned tensor products etc. are understood to be over $k$ if nothing else is indicated.

Let $R$ be a $k$-algebra. We denote the opposite algebra by $\overline{R}$, we let $R \ni r \mapsto \overline{r} \in \overline{R}$ denote the obvious $k$-algebra antiautomorphism, and abbreviate the enveloping algebra $R^e := R \otimes \overline{R}$. We write $r\overline{s} := r \otimes \overline{s} \in R \otimes \overline{R}$ for $r, s \in R$.

For $M, N \in R^e\mathcal{M}$ we let

$$\int^r \! M \otimes r N := M \otimes N/(\overline{m} \otimes n - m \otimes rn | r \in R, m \in M, n \in N)$$

and we let $\int^r \! M \otimes r N \subset M \otimes N$ denote the $k$-submodule consisting of all elements $\sum m_i \otimes n_i \in M \otimes N$ satisfying $\sum \overline{m}_i \otimes n_i = \sum m_i \otimes rn_i$ for all $r \in R$. Variations of the $\int_r$ and $\int^r$ notations, which are due to MacLane, will be used without further notice. We abbreviate $\int_r \! M \otimes r N = M \mathcal{O} R N$ for $M, N \in R^e\mathcal{M}$.

For two $R^e$-bimodules $M$ and $N$ we let

$$M \times_R N := \int^s \! \int^r \! \overline{M} \otimes r N_s.$$  

If $M, N$ are $R^e$-rings, then so is $M \times_R N$, with multiplication given by $(\sum m_i \otimes n_i)(\sum m'_i \otimes n'_i) = \sum m_i m'_i \otimes n_i n'_i$, and $R^e$-ring structure

$$R^e \ni r \otimes \overline{s} \mapsto r \otimes \overline{s} \in M \times_R N.$$

For $M, N, P \in R^e\mathcal{M}$ one defines

$$M \times_R P \times_R N := \int^{s,u} \! \int_{r,t} \! \overline{M} \otimes r \overline{P} \otimes s \pi \otimes t N_u$$

(where $\int^{s,u} := \int^s \int^u = \int^u \int^s$). There are associativity maps

$$(M \times_R P) \times_R N \xrightarrow{\alpha} M \times_R P \times_R N$$
$$M \times_R (P \times_R N) \xrightarrow{\alpha'} M \times_R P \times_R N$$

given on elements by the obvious formulas (doing nothing), but which need not be isomorphisms. If $M, N$ and $P$ are $R^e$-rings, so is $M \times_R N \times_R P$, and $\alpha, \alpha'$ are $R^e$-ring maps.

An $R^e$-ring structure on the algebra $E = \text{End}(R)$ is given by $r \otimes \overline{s} \mapsto (t \mapsto rts)$. We have, for any $M \in R^e\mathcal{M}$, two $R^e$-bimodule maps

$$\theta : M \times_R \text{End}(R) \to M; \quad m \otimes f \mapsto f(1)m$$
$$\theta' : \text{End}(R) \times_R M \to M; \quad f \otimes m \mapsto f(1)m.$$  

which are $R^e$-ring homomorphisms if $M$ is an $R^e$-ring.
A $\times_R$-bialgebra $L$ is defined to be an $R^e$-ring equipped with a comultiplication, a map $\Gamma: L \to L \times_R L$ of $R^e$-rings over $R^e$, and a counit, a map $C: L \to E$ of $R^e$-rings, such that

\begin{align}
(\Gamma \times_R L) \Gamma &= \alpha'(L \times_R \Gamma) \Gamma: L \to L \times_R L \times_R L \\
\theta(L \times_R C) \Gamma &= \theta(C \times_R L) \Gamma.
\end{align}

Note that an $R^e$-ring map $\Gamma: L \to L \times_R L$ induces a map $\Gamma_0: L \to L \circ_1 L$ in $R^e\mathcal{M}$, and an $R^e$-ring map $C: L \to E$ induces a map $C_0: L \ni \ell \mapsto C(\ell)(1) \in R$ in $R^e\mathcal{M}$.

One checks that $\Gamma$ and $C$ fulfill the equations (2.1) and (2.2) if and only if

\[(\Gamma_0 \circ L) \Gamma_0 = (L \circ_1 \Gamma_0) \Gamma_0: L \to L \circ_1 L \circ_1 L\]

and $(C_0 \circ L) \Gamma_0 = \text{id}_L = (L \circ C_0)$ hold. These mean that $L$, considered as an $R\times R$-bimodule via the left $R^e$-module structure, is an $R$-co-ring.

For $\times_R$-bialgebras we will make use of the variants $\Gamma(\ell) := \ell_{[1]} \otimes \ell_{[2]} \otimes \ell_{[3]} \in L \times_R L$ and

\[\alpha(\Gamma \times_R L) \Gamma(\ell) =: \ell_{[1]} \otimes \ell_{[2]} \otimes \ell_{[3]} \in L \times_R L \times_R L,\]

of usual Sweedler notation (reserving $\ell_{(1)} \otimes \ell_{(2)}$ for usual coalgebra structures).

If $L$ is a $\times_R$-bialgebra, then the tensor product $M \otimes_R N$ of $M, N \in \mathcal{L} \mathcal{M}$ can be endowed with an $L$-module structure by the usual formula $\ell(m \otimes n) = \ell_{[1]} m \otimes \ell_{[2]} n$.

The suitable definition of comodules over a $\times_R$-bialgebra $L$ is as follows: A left $L$-comodule is an $R$-bimodule $M$ together with a map $\lambda: M \to L \times_R M$ of $R$-modules such that

\[\alpha'(L \times_R \lambda) \lambda = \alpha(\Gamma \times_R M) \lambda: M \to L \times_R L \times_R M\]

and $\theta'(C \times_R M) \lambda = \text{id}_M$ hold. If we denote by $\lambda_0: M \to L \circ_0 M$ the composition of $\lambda$ with the inclusion of $L \circ_0 M$ into $L \times_R M$, then coassociativity is equivalent to $(L \otimes \lambda_0) \lambda_0 = (\Gamma_0 \circ \lambda) \lambda_0: M \to L \otimes L \circ_0 M$ and $(C_0 \circ \lambda) \lambda_0 = \text{id}_M$. We will denote by $L \mathcal{M}$ the category of left $L$-comodules. We will use Sweedler notation in the form $\lambda(m) = m_{[1]} \otimes m_{[0]}$ and $\alpha(\Lambda \times_R M)(m) = m_{[2]} \otimes m_{[1]} \otimes m_{[0]}$ for $L$-comodules.

The category $L \mathcal{M}$ of left $L$-comodules over a $\times_R$-bialgebra is monoidal. The tensor product of $M, N \in L \mathcal{M}$ is their tensor product $M \otimes_R N$ over $R$, equipped with the comodule structure

\[
M \otimes_R N \to L \times_R (M \otimes_R N)
\]

\[m \otimes n \mapsto m_{[1]}n_{[1]} \otimes m_{[0]} \otimes n_{[0]}\]

\section{Frobenius-separable algebras}

In this section we compile a few facts and notations on Frobenius-separable algebras, that is, Frobenius algebras that are separable so that the Frobenius system and the separability idempotent coincide. All of the material in this section is certainly folklore.

Let $R$ be a $k$-algebra. Recall that $R$ is Frobenius if there is a Frobenius system $(\phi, e)$ for $R$, which in turn consists by definition of a $k$-linear map $\phi: R \to k$, and an element $e = e^{(1)} \otimes e^{(2)} \in R \otimes R$ such that

\[\forall r \in R: r = \phi(re^{(1)})e^{(2)} = e^{(1)}\phi(e^{(2)}r).\]

Equivalently, $R$ is finite dimensional, and there is a $k$-linear map $\phi: R \to k$ such that the bilinear form $B_\phi: R \times R \to k$ given by $B_\phi(x, y) = \phi(xy)$ is nondegenerate. It follows that $e \in R \otimes R$ is a Casimir element in the sense that $(x \otimes 1)e = e(1 \otimes x)$
in the algebra $R \otimes R$ for each $x \in R$: by nondegeneracy of $B_\phi$ it is sufficient to observe $\phi(yxe^{(1)}e^{(2)}) = yx = \phi(ye^{(1)})e^{(2)}x$ for all $y \in R$. Recall that the Frobenius automorphism $\theta: R \to R$ defined by the Frobenius system $(\phi, e)$ is by definition the linear map $\theta: R \to R$ with $\phi(xy) = \phi(y\theta(x))$ for all $x, y \in R$. It is an algebra automorphism. We have $(1 \otimes x)e = e(\theta(x) \otimes 1)$ in $R \otimes R$ for all $x \in R$, by the calculation $\phi(ye^{(1)}\theta(x))e^{(2)} = \phi(xye^{(1)})e^{(2)} = xy = \phi(ye^{(1)})xe^{(2)}$. It is easy to see that this property characterizes $\theta$, so that $(\phi, e)$ is a symmetric Frobenius system (i.e., $B_\phi$ is symmetric) if and only if $\theta$ is the identity if and only if $(\phi, e^{(2)} \otimes e^{(1)})$ is a Frobenius system if and only if only if $e^{(2)} \otimes e^{(1)} = e$.

If $(\phi, e)$ is a Frobenius system, and $t \in R$ is invertible, then $(\psi, f)$ defined by $\psi(x) = \phi(tx)$ and $f = (1 \otimes t^{-1})e$, is also a Frobenius system by the calculations $\psi(xf^{(1)})f^{(2)} = \phi(txe^{(1)})t^{-1}e^{(2)} = t^{-1}tx = x$ and $f^{(1)}\psi(f^{(2)}x) = e^{(1)}\phi(tt^{-1}e^{(2)}x) = e^{(1)}\phi(e^{(2)}x) = x$.

Conversely, if $(\psi, f)$ is another Frobenius system, define $t := \psi(e^{(1)})e^{(2)}$. Then $\phi(tx) = \psi(e^{(1)})\phi(e^{(2)}x) = \psi(x)$ for all $x \in R$, further $e = (1 \otimes t)f$ since $f^{(1)}\phi(tf^{(2)}x) = f^{(1)}\psi(f^{(2)}x) = x = e^{(1)}\phi(e^{(2)}x)$ for all $x \in R$. Finally $t$ is invertible with inverse $\phi(f^{(1)})f^{(2)}$ since $\phi(f^{(1)})f^{(2)}t = \phi(tf^{(1)})f^{(2)} = \psi(f^{(1)})f^{(2)} = 1$ and $t\phi(f^{(1)})f^{(2)} = \phi(e^{(1)})e^{(2)} = 1$.

Let $(\phi, e)$ be a Frobenius system. Then $e$ is a separability idempotent for $R$ if and only if $\nabla(e) = 1$, in which case we say that $(\phi, e)$ is an idempotent Frobenius system. If an idempotent Frobenius system exists, we will say that $R$ is Frobenius-separable. While every separable algebra $R$ is automatically symmetric [10, Expl.(16.58)], it is not necessarily Frobenius-separable: if $k$ is a field of characteristic $p > 0$, then $M_p(k)$ is separable (hence—and also obviously—Frobenius), but not Frobenius-separable. However, if $R$ is a commutative separable $k$-algebra, then $R$ is Frobenius-separable with respect to the trace functional $\phi: R \to k$. To see this it suffices to treat the case where $R$ is a field. Let $e$ be a separability idempotent, and write $e = \sum_{i=1}^n x_i \otimes y_i$ with $n$ minimal. Then the elements $x_i$ generate $R$ as a $k$-space (hence they are a basis). For take any $x \in R$, put $t := x_1^{-1}x$, and consider $\phi \in R^*$ with $\varphi(y_i) = \delta_{1,i}$. Then

$$x = (1 \otimes \varphi)(\sum tx_i \otimes y_i) = \sum x_i \varphi(y_i)t.$$  

Similarly the $y_i$ form a basis of $R$. Now let $\phi(r)$ be the trace of multiplication by $r$ as an endomorphism of $R$; this defines $\phi: R \to k$, and we claim that $(\phi, e)$ is an idempotent Frobenius system. Let $(y^i)$ be the dual basis of $(y_i)$. Then $\phi(r) = \sum y^i \varphi(y_ir)$, so that

$$\phi(xe^{(1)}e^{(2)}) = \sum \phi(xx_i)y_i = \sum x^i(xx_jx_i)y_i = \sum x^i(x_i)y_i xx_j = \sum y_j xx_j = x$$  

follows for $x \in R$. Similarly $e^{(1)}\phi(e^{(2)}x) = x$.

If $(\phi, e)$ and $(\psi, f)$ are two idempotent Frobenius systems, then there is an invertible $t \in R$ with $e^{(1)}t^{-1}e^{(2)} = 1$, such that $\psi(x) = \phi(tx)$ for all $x$ and $f = (1 \otimes t^{-1})e$.

4. WEAK HOPF ALGEBRAS

A weak bialgebra $H = (H, \nabla, \Delta)$ is by definition an algebra and coalgebra $H$ such that the comultiplication $\Delta: H \to H \otimes H$ is multiplicative, and the following
four conditions hold for all $f, g, h \in H$:

(4.1) $\varepsilon(fgh) = \varepsilon(fg_1)\varepsilon(g_2)h$,  
(4.2) $\varepsilon(fgh) = \varepsilon(fg_2)\varepsilon(g_1)h$,  
(4.3) $1(1) \otimes 1(2) \otimes 1(3) = (\Delta(1) \otimes 1)(1 \otimes \Delta(1))$,  
(4.4) $1(1) \otimes 1(2) \otimes 1(3) = (1 \otimes \Delta(1))(\Delta(1) \otimes 1)$.

These four conditions weaken the conditions of multiplicativity of the counit, and comultiplicativity of the unit, which are not required in a weak bialgebra (whereas $\varepsilon(1) = 1$ is an easy consequence of the axioms). Note that by the symmetries of the definition, the opposite $H^{\text{cop}}$, coopposite $H^{\text{coop}}$, and the opposite and coopposite (or biopposite) $H^{\text{bop}}$ are weak bialgebras as well.

We define the source and target counital maps $\varepsilon_{s,t} : H \to H$ of a weak bialgebra $H$ to be

\[ \varepsilon_s(h) = 1(1)\varepsilon(h1(2)), \]
\[ \varepsilon_t(h) = \varepsilon(1(1)h)1(2). \]

And denote their images by $H_{s,t} := \varepsilon_{s,t}(H)$; these are called the source and target counital subalgebras (see below) of $H$. We note the variants $\varepsilon'_{s,t}$, with

\[ \varepsilon'_s(h) = 1(1)\varepsilon(1(2)h), \]
\[ \varepsilon'_t(h) = \varepsilon(h1(1))1(2). \]

Obviously these are the source and target counital maps for the weak bialgebra $H^{\text{cop}}$, which means that general statements on them will follow from general statements on $\varepsilon_{s,t}$ mutatis mutandis. We’ll use in the same way that $\varepsilon_s$ is the target counital map of $H^{\text{bop}}$.

Note $h(1)\varepsilon_s(h(2)) = h(1)1(1)\varepsilon(h(2)1(2)) = h$, so also

\[ h(1)\varepsilon_s(h(2)) = \varepsilon_s(h(1))h(2) = \varepsilon'_s(h(2))h(1) = h(2)\varepsilon'_t(h(1)) = h \]

for all $h \in H$. Moreover

\[ \varepsilon_t(1(1)h)1(2) = \varepsilon(1'(1)1(1)h)1'(2)1(2) = \varepsilon_t(h) \]

We have

\[ 1(1) \otimes \varepsilon_t(1(2)) = 1(1) \otimes \varepsilon(1'(1)1(2))1'(2) = 1(1) \otimes \varepsilon(1(2))1(3) = 1(1) \otimes 1(2) \]

hence

\[ 1(1) \otimes 1(2) = \varepsilon_s(1(1)) \otimes 1(2) = \varepsilon_s(1(1)) \otimes \varepsilon_t(1(2)) \]

and the same identities with $\varepsilon_{s,t}$ replaced by $\varepsilon'_{s,t}$. In particular $\Delta(1) \in H_s \otimes H_t$. It also follows that $\varepsilon_{s,t}(x) = \varepsilon'_{s,t}(x) = x$ for all $x \in H_{s,t}$, so that $\varepsilon_t, \varepsilon'_t$ are idempotent projectors onto $H_t$.

The calculation

\[ \Delta(\varepsilon_t(x)) = \varepsilon(1(1)h)1(2) \otimes 1(3) = \varepsilon(1(1)h)1(2)1'(1) \otimes 1'(2) = \varepsilon_t(h)1(1) \otimes 1(2) \]

for all $h \in H$ shows the first part of

(4.6) $\forall x \in H_t : \Delta(x) = x1(1) \otimes 1(2) = 1(1)x \otimes 1(2)$,

the second is proved similarly, and as a corollary we have

(4.7) $\forall x \in H_s : \Delta(x) = 1(1) \otimes x1(2) = 1(1) \otimes 1(2)x$. 

For all \( g, h \in H \) we have

\[
\varepsilon(gh) = \varepsilon(g1_{(2)})\varepsilon(1_{(1)}h) = \varepsilon(g\varepsilon_t(h))
\]

by (4.2), hence

\[
\varepsilon_t(gh) = \varepsilon(1_{(1)}gh)1_{(2)} = \varepsilon(1_{(1)}g\varepsilon_t(h))1_{(2)} = \varepsilon_t(g\varepsilon_t(h)),
\]

and further

\[
g\varepsilon_t(h) = \varepsilon_t(g(1)\varepsilon_t(h))1(2)g(2)\varepsilon_t(h)(2) = \varepsilon_t(g(1)\varepsilon_t(h))g(2) = \varepsilon_t(g(1)h)g(2)
\]

hence

\[
\forall x \in H_t \forall h \in H : x\varepsilon_t(h) = \varepsilon_t(1_{(1)}xh)1_{(2)} = \varepsilon_t(xh).
\]

In particular \( H_t \) is multiplicatively closed; it is a subalgebra because also \( \varepsilon_t(1) = \varepsilon(1'_{(1)}1'_{(2)}) = \varepsilon(1'_{(1)}1'_{(2)}) = 1. \)

For \( g, h \in H \) we have

\[
\varepsilon_t(g)\varepsilon_s(h) = \varepsilon(1_{(1)}g)1_{(2)}1'_{(1)}\varepsilon(h1'_{(2)}) = \varepsilon(1_{(1)}g)1'_{(1)}1_{(2)}\varepsilon(h1'_{(2)}) = \varepsilon_s(h)\varepsilon_t(g),
\]

so that the subalgebras \( H_s \) and \( H_t \) commute element-wise.

**Lemma 4.1.** Let \( H \) be a weak bialgebra. The target counital map \( \varepsilon_t \) induces an algebra antiisomorphism \( H_s \rightarrow H_t \), whose inverse is induced by \( \varepsilon'_s \).

**Proof.** To see that \( \varepsilon_t \) is an an anti-algebra map we compute more generally

\[
\varepsilon_t(gh) = \varepsilon_t(1_{(1)}xh)1_{(2)} = \varepsilon_t(h)\varepsilon_t(1)
\]

for all \( y \in H_s \) and \( h \in H \), using (4.9) and (4.10).

To prove \( \varepsilon'_s \) induces an inverse isomorphism to the map induced by \( \varepsilon_t \), we use that more generally

\[
\forall h \in H : \varepsilon_t\varepsilon'_s(h) = \varepsilon_t(h)
\]

by the calculation

\[
\varepsilon_t\varepsilon'_s(h) = \varepsilon(1_{(1)}\varepsilon'_s(h))1_{(2)} = \varepsilon(1_{(1)}1'_{(1)}\varepsilon(h1'_{(2)}))1_{(2)} \overset{(4.1)}{=} \varepsilon(1_{(1)}h1_{(2)}) = \varepsilon_t(h)
\]

Applying this to \( H^{bop} \) yields \( \varepsilon'_s\varepsilon_t(h) = \varepsilon'_s(h) \) for all \( h \in H \), and this taken together with (4.11) proves the claim. \( \square \)

**Proposition 4.2.** Let \( H \) be a weak bialgebra. Then the target counital subalgebra \( H_t \) is Frobenius-separable with idempotent Frobenius system

\[
(e|_{H_t}, (\varepsilon_t \otimes H)\Delta(1))
\]

**Proof.** The claimed idempotent Frobenius system is given more explicitly by

\[
e = \varepsilon_t(1_{(1)}) \otimes 1_{(2)} = \varepsilon(1'_{(1)}1_{(1)})1'_{(2)} \otimes 1_{(2)}.
\]

We have, for all \( x \in H_t \):

\[
\varepsilon(x\varepsilon^{(1)}(x))\varepsilon^{(2)}(x) = \varepsilon(1'_{(1)}1_{(1)})\varepsilon(x1'_{(1)}1_{(2)}) \overset{(4.4)}{=} \varepsilon(x1_{(1)})1_{(2)} = \varepsilon'_t(x) = x
\]

and

\[
e^{(1)}\varepsilon(x\varepsilon^{(2)}(x)) = \varepsilon(1'_{(1)}1_{(1)})1'_{(2)}\varepsilon(1_{(2)}x) \overset{(4.3)}{=} \varepsilon(1_{(1)}x)1'_{(2)} = \varepsilon_t(x) = x
\]

while \( \nabla(e) = 1 \) is quite obvious. \( \square \)
It follows that
\[(4.12) \quad \forall x \in H_t: x\varepsilon_t(1_{(1)}) \otimes 1_{(2)} = \varepsilon_t(1_{(1)}) \otimes 1_{(2)}x.\]

Applying the Lemma to \(H^\text{op}\) yields that \(H^\text{op}\) is Frobenius-separable with idempotent Frobenius system \((\varepsilon, 1_{(1)} \otimes \varepsilon_s(1_{(2)}))\). In particular
\[(4.13) \quad \forall y \in H_s: 1_{(1)}y \otimes \varepsilon_s(1_{(2)}) = 1_{(1)} \otimes y\varepsilon_s(1_{(2)}).\]

Applying \(\varepsilon'_s\) (which is an anti-algebra map restricted to \(H_t\)) to the first tensor factor of (4.12), we obtain
\[(4.14) \quad \forall x \in H_t: 1_{(1)}\varepsilon'_s(x) \otimes 1_{(2)} = 1_{(1)} \otimes 1_{(2)}x.\]

5. Weak bialgebras are \(\times_R\)-bialgebras

**Theorem 5.1.** Let \((H, \Delta, \varepsilon)\) be a weak bialgebra. Put \(R := H_t\). Then the structure \((H, \Gamma, C)\) of a \(\times_R\)-bialgebra on \(H\) is given as follows: The \(R^c\)-ring structure of \(H\) is given by \(s(x \otimes y) = x\varepsilon'(y)\), the comultiplication \(\Gamma: H \to H \times_R H \subset H \circ H\) is the composition of \(\Delta\) with the canonical surjection \(H \otimes H \to H \circ H\). The counit is
\[C : H \ni h \mapsto (x \mapsto \varepsilon_t(\varepsilon h)) \in \text{End}(R).\]

**Proof.** \(H\) is an \(R^c\)-ring as claimed since \(\varepsilon'_s\) induces an antiisomorphism of \(H_t\) with \(H_s\), and \(H_s\) and \(H_t\) commute element-wise.

That \(\Gamma_0 : H \to H \otimes H \to H \circ H\) takes values in \(H \times_R H\) follows from
\[\Gamma(h) = \Gamma(h \cdot 1) = h_{(1)}1_{(1)} \otimes h_{(2)}1_{(2)}\]
and (4.14). It is clear that \(\Gamma\) is an algebra map, since \(\Delta\) is multiplicative and \(\Gamma(1) = 1\) in \(H \circ H\). Also, \(\Gamma\) is a map of \(R^c\)-rings by (4.7) and (4.6), and obviously coassociative since \(\Delta\) is.

The map \(C\) is unit-preserving since \(\varepsilon_t\) is idempotent, and multiplicative since
\[C(g)C(h)(x) = C(g)(\varepsilon_t(\varepsilon h))\varepsilon_t(ghx) = \varepsilon_t(ghx)\]
for all \(g, h \in H\) and \(x \in H_t\), using (4.9). Moreover \(C(y)(x) = \varepsilon_t(\varepsilon x) = xy\) and \(C(y)(x) = \varepsilon_t(\varepsilon_s(y)x) = x\varepsilon_t\varepsilon'_s(y) = xy\) for \(x, y \in H_t\) show that \(C\) is a map of \(R^c\)-rings.

It remains to check that \(C\) is a counit: We have
\[C(h_{[1]})(h_{[2]} = \varepsilon(1_{(1)}h_{[1]}1_{(2)}h_{[2]} = \varepsilon(1_{(1)}h_{(1)})1_{(2)}h_{(2)} = h\]
as well as
\[\overline{C(h_{[2]})(h_{[1]})} = \varepsilon(1_{(1)}h_{[2]}1_{(2)}h_{[1]} = \varepsilon(1_{(1)}h_{(2)})\varepsilon'_s(1_{(2)}h_{(1)})\]
\[= \varepsilon(1_{(1)}h_{(2)})1'_{(1)}(1'_{(2)}1_{(2)}h_{(1)} = (4.1) \varepsilon(1'_{(2)}h_{(2)})1'_{(1)}h_{(1)} = h\]
for all \(h \in H\). \(\square\)

The theorem above (which is [5, Prop.2.3.1] in the case where \(H\) is a weak Hopf algebra) shows that any weak bialgebra is a \(\times_R\)-bialgebra in which, by Proposition 4.2, \(R\) is Frobenius-separable. We will also prove a converse Theorem 5.5. Just as in the case of commutative separable \(R\) treated in [18], this is based on the following simple observation:
Remark 5.2. Let $R$ be a separable algebra with separability idempotent $e$. Then for $M \in \mathcal{M}_R$ and $N \in R\mathcal{M}$ the identity on $M \otimes N$ induces an isomorphism

$$\gamma : Me^{(1)} \otimes e^{(2)}N \to M \otimes N$$

with inverse given by $\gamma^{-1}(m \otimes n) = me^{(1)} \otimes e^{(2)}n$.

Before using this (implicitly) to prove Theorem 5.5, we will use it to compare the tensor product defined on modules over a weak bialgebra by Böhm and Szlachányi [3] with the tensor product defined on the modules over the corresponding $\times_R$-bialgebra. The tensor product on $H$-modules for a weak bialgebra $H$ is given by $M \otimes N := \Delta(1)(M \otimes N)$ for $M, N \in H\mathcal{M}$, with the diagonal left $H$-module structure induced via $\Delta$.

**Proposition 5.3.** Let $H$ be a weak bialgebra. Then the isomorphisms

$$\gamma = \gamma_{MN} : M \otimes N \to M \circ N$$

for $M, N \in H\mathcal{M}$ endow the identity functor with the structure of a monoidal functor

$$(Id, \gamma) : (H\mathcal{M}, \circ) \to (H\mathcal{M}, \otimes)$$

**Proof.** The idempotent Frobenius system we have found for $R = H_t$ in Proposition 4.2 is such that $e^{(1)} \otimes e^{(2)} = \Delta(1)$. Thus $\gamma$ is a vector space isomorphism by Remark 5.2; it is linear by definition of comultiplication in the $\times_R$-bialgebra associated to the weak bialgebra $H$. Coherence of the monoidal functor is evident since $\gamma$ is induced by the identity (and we skip treating unit objects altogether). \(\square\)

**Remark 5.4.** The arguments used in Proposition 5.3 could be rewritten to be a different proof of Theorem 5.1: A weak bialgebra $H$ is an $R^\circ$-ring for $R = R_t$; since $R$ is separable, we can use Remark 5.2 to endow the underlying functor $H\mathcal{M} \to R^\circ\mathcal{M}$ with the structure of a monoidal functor. It then follows from [17, Thm.5.1] that $H$ has a $\times_R$-bialgebra structure.

We now proceed to prove the converse of Theorem 5.1:

**Theorem 5.5.** Let $R$ be a Frobenius-separable algebra with idempotent Frobenius system $(\phi, e)$. Let $(H, \Gamma, C)$ be a $\times_R$-bialgebra. Then the structure $(H, \Delta, \varepsilon)$ of a weak bialgebra on $H$ is given by

$$\Delta(h) = e^{(1)}h[1] \otimes e^{(2)}h[2]$$

$$\varepsilon(h) = \phi(C(h)(1))$$

**Proof.** The map $\Delta$ is well-defined since

$$f : H \circ H \ni g \otimes h \mapsto e^{(1)}g \otimes e^{(2)}h \in H \otimes H$$

is well-defined, since $e^{(1)}xg \otimes e^{(2)}h = xe^{(1)}g \otimes e^{(2)}h = e^{(1)}g \otimes e^{(2)}xh$ holds for all $g, h \in H$ and $x \in R$. We have

$$\Delta(h[1]) \otimes h[2] = e^{(1)}h[1][1] \otimes e^{(2)}(\varepsilon(h)[1]) \otimes \varepsilon(h)[2]$$

$$= e^{(1)}h[1][1] \otimes e^{(2)}e^{(1)}h[1][2] \otimes \varepsilon(h)[2] = e^{(1)}h[1][1] \otimes e^{(2)}e^{(1)}h[2][1] \otimes \varepsilon(h)[2][2]$$

$$= e^{(1)}h[1][1] \otimes e^{(2)}h[2][1] \otimes e^{(2)}(e^{(1)}h[2][2]) = h[1] \otimes \Delta(h[2])$$
showing that $\Delta$ is coassociative. The map $\varepsilon$ is a counit since

$$h(1)\varepsilon(h(2)) = e(1)h(1)\phi(C(e(2)h(2))(1)) = e(1)h(1)\phi(e(2)C(h(2))(1)) = C(h(2))(1)h(1) = h$$

and

$$\varepsilon(h(1))h(2) = \phi(C(e(1)h(1))(1))e(2)h(2) = \phi(C(h(1))(1)e(1)e(2)h(2) = C(h(1))(1)h(2) = h$$

$\Delta$ is multiplicative by the calculation

$$\Delta(g)\Delta(h) = e(1)g[1]e(1)h[1] \otimes e(2)g[2]e(2)h[2] = e(1)g[1]h[1] \otimes e(2)e(1)h[2] = e(1)g[1]h[1] \otimes e(2)g[2]h[2] = \Delta(gh)$$

for all $g, h \in H$, using $\Gamma(g) \in H \times RH$.

We have

$$\varepsilon(\Gamma(1,2))\varepsilon(1)h(2) = \varepsilon(ge(1))\varepsilon(e(2)h) = \phi(C(ge(1))(1))\phi(C(e(2)h)(1))$$

$$= \phi(C(g)(e(1)))\phi(C(e(2)C(h)(1)) = \phi(C(g)(C(h)(1)) = \phi(C(gh)(1)) = \varepsilon(gh)$$

and

$$\varepsilon(\Gamma(1,2))\varepsilon(1)h(1) = \phi(C(ge(2))(1))\phi(C(e(1)h)(1)) = \phi(C(g)(e(2)))\phi(C(h)(1)e(1))$$

$$= \phi(C(g)(C(h)(1))) = \varepsilon(gh)$$

for $g, h \in H$,

$$(H \otimes \Delta)\Delta(1) = e(1) \otimes \Delta(e(2)) = e(1) \otimes e(1)(e(2))[1] \otimes e(2)(e(2))[2]$$

$$= e(1) \otimes e(1)(e(2) \otimes e(2)) = \Delta(1) \otimes 1 \otimes e(1) \otimes e(2) = 1 \otimes e(1) \otimes e(2) = 1 \otimes (1 \otimes \Delta(1))(\Delta(1) \otimes 1). \square$$

Remark 5.6. Let $(H, \Gamma, C)$ be a $\times RH$-bialgebra. Then for any idempotent Frobenius system $(\phi, \varepsilon)$ we obtain a weak bialgebra structure $(H, \Delta_\phi, \varepsilon_\phi)$ from Theorem 5.5.

On the other hand, if a weak bialgebra structure $(H, \Delta, \varepsilon)$ is given, we obtain a $\times RH$-bialgebra structure from Theorem 5.5, along with an idempotent Frobenius system for the target counital subalgebra $R := H_1$ from Proposition 4.2.

Assume we start with an idempotent Frobenius system on $R$ and a $\times RH$-bialgebra $(H, \Gamma, C)$. Consider the weak bialgebra $(H, \Delta, \varepsilon)$ obtained from it. Assuming that the maps from $R$ and from $\overline{R}$ to $H$ making $H$ an $R^*$-ring are injective, it is easy to see that $H_1 \cong R$, and that the idempotent Frobenius system on $H_1$ obtained from Proposition 4.2 is the same as the idempotent Frobenius system on $R$ originally given.

On the other hand, assume we start with a weak bialgebra $(H, \Delta, \varepsilon)$, and consider the Frobenius-separable algebra $R = H_1$ with idempotent Frobenius system $(\phi, \varepsilon)$ as in Proposition 4.2, and the $\times RH$-bialgebra $(H, \Gamma, \varepsilon)$ as in Theorem 5.1. Then for any choice of an idempotent Frobenius system $(\psi, f)$ on $R$ we obtain a weak bialgebra structure $(H, \Delta_\psi, \varepsilon_\psi)$ from Theorem 5.5. It is quite obvious that $\Delta_\phi = \Delta$ and $\varepsilon_\phi = \varepsilon$, that is, we get the original weak bialgebra back provided we choose the idempotent Frobenius system it defines. What happens if we choose another one?
Then there is an invertible $t \in R$ with $e^{(1)}t^{-1}e^{(2)} = 1$, $\psi(x) = \phi(tx)$ for all $x \in R$, and $f = (1 \otimes t^{-1})\epsilon$, and we obtain

$$\Delta_\psi(h) = f^{(1)}h_{(1)} \otimes f^{(2)}h_{(2)} = h_{(1)} \otimes t^{-1}h_{(2)}$$

and

$$\varepsilon_\psi(h) = \varepsilon(tC(h)(1)) = \varepsilon(t\varepsilon_t(h)) = \varepsilon(th)$$

This kind of twisting of a weak bialgebra structure by an invertible element in the target counital subalgebra is considered by Nikshych [13]. We see that Theorem 5.1 and Theorem 5.5 relate Takeuchi’s $\times_R$-bialgebras to weak bialgebras up to such twists, which corresponds well to the viewpoint in [13] that twistings by invertible elements in the counital subalgebra should be considered as particularly irrelevant for the structure of $H$. Weak bialgebras that are such twists of each other can simply be obtained as different weak bialgebra versions of the same $\times_R$-bialgebra.

6. WEAK HOPF ALGEBRAS ARE $\times_R$-HOPF ALGEBRAS

Etingof and Nikshych have shown that a weak Hopf algebra is a Hopf algebroid in the sense of Lu.

In this section we compare the weak Hopf algebra axioms to a different notion of “Hopf algebroid”, namely that of a $\times_R$-Hopf algebra introduced in [19]. By definition [19, Def.3.5], a $\times_R$-bialgebra is a $\times_R$-Hopf algebra if and only if the canonical map

$$H \otimes H \ni g \otimes h \mapsto g_{[1]} \otimes g_{[2]}h \in H \circ H$$

is a bijection. This is analogous to a well-known characterization of ordinary bialgebras. Moreover, the definition is backed in [19] by a characterization of $\times_R$-Hopf algebras through a canonical property of their module categories.

By definition, a weak bialgebra $H$ is a weak Hopf algebra if there is an endomorphism $S$ of the $k$-space $H$ such that for all $h \in H$

$$S(h_{(1)})h_{(2)} = \varepsilon_s(h),$$

$$h_{(1)}S(h_{(2)}) = \varepsilon_t(h),$$

$$S(h_{(1)})h_{(2)}S(h_{(3)}) = S(h).$$

The axioms imply immediately that

$$S(h_{(1)})\varepsilon_t(h_{(2)}) = S(h) = \varepsilon_s(h_{(1)})S(h_{(2)}).$$

Hence we have, for $x \in H_a$,

$$\varepsilon_s(xh_{(1)})S(h_{(2)}) = S(h_{(1)})xh_{(2)}S(h_{(3)}) = S(h_{(1)})x\varepsilon_t(h_{(2)}) = S(h_{(1)})\varepsilon_t(h_{(2)})x = S(h)x.$$ 

The antipode is an algebra antihomomorphism by

$$S(gh) = S(g_{(1)}h_{(1)})\varepsilon_t(g_{(2)}h_{(2)}) = S(g_{(1)}h_{(1)})\varepsilon_t(g_{(2)}\varepsilon_t(h_{(2)}))$$

$$= S(g_{(1)}h_{(1)})g_{(3)}\varepsilon_t(h_{(2)})S(g_{(3)}) = S(g_{(1)}h_{(1)})g_{(2)}h_{(2)}S(h_{(3)})S(g_{(3)})$$

$$= \varepsilon_s(g_{(1)}h_{(1)})S(h_{(2)})S(g_{(2)}) = \varepsilon_s(\varepsilon_s(g_{(1)})h_{(1)})S(h_{(2)})S(g_{(2)})$$

and

$$S(1) = S(1_{(1)})1_{(2)}S(1_{(3)}) = S(1_{(1)})1_{(2)}1'_{(1)}S(1'_{(2)}) = \varepsilon_s(1)\varepsilon_t(1') = 1.$$
Theorem 6.1. Let $H$ be a weak bialgebra. Then $H$ is a weak Hopf algebra if and only if the map
\[ \beta_0: H \otimes H \ni g \otimes h \mapsto g(1) \otimes g(2)h \in H \otimes H \]
induces an isomorphism
\[ \beta: H \otimes H \to \Delta(1)(H \otimes H). \]

Proof. First, assume that $H$ has an antipode $S$. Define $\overline{\beta}_0: H \otimes H \to H \otimes H$ by $\overline{\beta}(g \otimes h) = g(1) \otimes S(g(3))h$. Then
\[
\overline{\beta}_0 \beta_0(g \otimes h) = \beta(g(1) \otimes S(g(3))h) = g(1) \otimes g(2)S(g(3))h = g(1) \otimes \varepsilon_s(g(2))h
\]
\[
= 1(1)g(1) \otimes \varepsilon_s(1(2)g(3))h = 1(1)g(1) \otimes \varepsilon(1'(1)1(2)g(3))1'(2)h
\]
\[
= 1(1)g(1) \otimes \varepsilon(1(2)g(3))1(3)h = 1(1)g \otimes 1(2)h
\]
and
\[
\overline{\beta}_0 \beta_0(g \otimes h) = g(1) \otimes S(g(2))g(3)h = g(1) \otimes \varepsilon_s(g(2))h = g(1)\varepsilon_s(g(2)) \otimes h = g \otimes h
\]
Thus the restriction of $\overline{\beta}_0 \beta_0$ is an inverse to $\beta$.

Now assume that $\beta$ has an inverse $\beta^{-1}$. Define $\pi: H \otimes H, H \to H\otimes H$ by $\pi(g \otimes h) = \varepsilon_s(g)h$, and define $S: H \to H$ by $S(h) = \pi(\beta^{-1}(1(1)h \otimes 1(2)))$ for $h \in H$. We claim that $S$ is an antipode for $H$. For this we first compute
\[
S(h(1))h(2) = \pi(\beta^{-1}(1(1)h(1) \otimes 1(2)))h(2) = \pi(\beta^{-1}(1(1)h(1) \otimes 1(2))(1 \otimes h(2)))
\]
\[
= \pi(\beta^{-1}(1(1)h(1) \otimes 1(2))h(2)) = \pi(\beta^{-1}(h(1) \otimes h(2))) = \pi(h \otimes 1) = \varepsilon_s(h).
\]
Next, we claim that the inverse of $\beta$ is the restriction of the map
\[ \gamma: H \otimes H \ni g \otimes h \mapsto g(1) \otimes S(g(2))h \in H \otimes H. \]
This is verified by the calculation
\[
\gamma \beta_0(g \otimes h) = \gamma(g(1) \otimes g(2)h) = g(1) \otimes S(g(2))g(3)h = g(1) \otimes \varepsilon_s(g(2))h
\]
\[
= g(1)\varepsilon_s(g(2)) \otimes h = g \otimes h.
\]
Using, for $y \in H_s$,
\[ S(y \Delta) = \pi(\beta^{-1}(1(1)y \otimes 1(2))) = \pi(\beta^{-1}(1(1)y \otimes 1(2))\varepsilon(y))
\]
\[
= \pi(\beta^{-1}(1(1)y \otimes 1(2))\varepsilon(y)) = \pi(h)\varepsilon(y),
\]
we find
\[ 1(1)h \otimes 1(2) = \beta^{-1}(1(1)h \otimes 1(2)) = \beta(h(1) \otimes S(1(1)h(2)))1(2)
\]
\[ = \beta(h(1) \otimes S(h(2))\varepsilon(1(1)h(2))) = \beta(h(1) \otimes S(h(2))) = h(1) \otimes h(2)S(h(3)).
\]
and can apply $\varepsilon \otimes H$ to the result to obtain $\varepsilon(h) = h(1)S(h(2))$. We finish the proof by calculating
\[ S(h(1))h(2)S(h(3)) = S(h(1))\varepsilon(h(2)) = S(h(1))\varepsilon \varepsilon'_s(h(2)) = S(\varepsilon'(h(2))h(1)) = S(h)
\]
for all $h \in H$. □

Corollary 6.2. Let $H$ be a weak bialgebra. Then the following are equivalent:
1. $H$ is a weak Hopf algebra.
2. The associated $\times_R\text{-bialgebra}$ $H$ is a $\times_R\text{-Hopf algebra}$. 

Proof. The identity induces an isomorphism $\gamma \Delta(1)(H \otimes H) \to H \circ H$ by Proposition 5.3. The composition $\gamma \beta$ is the map

$\Delta H \ni g \otimes h \mapsto g_1 \otimes g_2 h \in H \circ H$

required to be bijective in the definition of a $\times_R$-Hopf algebra.

For ordinary Hopf algebras, a well-known application of the characterization Theorem 6.1 is due to Nichols [12]: Any finite dimensional quotient bialgebra $H/I$ of a Hopf algebra $H$ is itself a Hopf algebra. Dually, every finite-dimensional subbialgebra of a Hopf algebra is itself a Hopf algebra. Our results will not be quite as striking. We cannot prove that a finite-dimensional weak subbialgebra $B \subset H$ of a weak Hopf algebra $H$ is necessarily a weak Hopf algebra. But at least we can give a criterion purely in terms of the module structure of $B$ over the source and target counital subalgebras.

To prepare, we note an observation of Nikshych and Vainerman [14, 2.1.12]:

Lemma 6.3. Let $f: B \to H$ be a homomorphism of weak bialgebras. Then $f$ induces isomorphisms $B \cong H_t$ and $B \cong H_s$.

Proof. We only treat the target counital subalgebra. It is trivial to check that $f(B_t) \subset H_t$. We denote the induced map $B \to H_t$ by $f$ again. Define

$g: H_t \ni x \mapsto \varepsilon(x f(1_{(1)})) 1_{(2)} \in B_t$.

Then

$g(f(x)) = \varepsilon(f(x) f(1_{(1)})) 1_{(2)} = \varepsilon(f(x 1_{(1)})) 1_{(2)} = \varepsilon(x 1_{(1)}) 1_{(2)} = x$

for all $x \in B_t$, and

$f g(x) = \varepsilon(x f(1_{(1)})) f(1_{(2)}) = \varepsilon(x f(1_{(1)})) f(1_{(2)}) = \varepsilon(x 1_{(1)}) 1_{(2)} = x$

for all $x \in H_t$, so that $g$ is inverse to $f$.

Theorem 6.4. Let $H$ be a weak Hopf algebra, and $B \subset H$ a finite-dimensional weak subbialgebra (i.e. subalgebra and subcoalgebra) of $H$. The following are equivalent:

1. $B$ is a weak Hopf algebra.
2. The right $B_s$-module $B$ is isomorphic to the $B_t$-module $B$ obtained by restricting the left $B_t$-module $B$ along $\varepsilon_1$.

Proof. As a special case of the preceding Lemma we have $B_t = H_t$ and $B_s = H_s$. For the implication (1)⇒(2) we need to use that the antipode of a finite-dimensional quasi-Hopf algebra is bijective [1, 2.10]. Now $S$ is an algebra antiautomorphism, and for $y \in H_s$

$S(y) = S(y_{(1)}) \varepsilon_t(y_{(2)}) = S(1_{(1)}) \varepsilon_t(y 1_{(2)}) = S(1_{(1)}) 1_{(2)} \varepsilon_t(y) = \varepsilon_t(y)$,

so that (2) follows.

Now assume (2), and fix an isomorphism $f: B \to B$ satisfying $f(b \varepsilon'_t(x)) = x f(b)$ for all $b \in B$ and $x \in H_t$. Then

$B \otimes B \ni b \otimes c \mapsto c \otimes f(b) \in B \circ B$

is an isomorphism of vector spaces, hence its domain and codomain have the same dimension. The canonical map

$B \otimes B \ni b \otimes c \mapsto b_{[1]} \otimes b_{[2]} c \in B \circ B$
is the restriction (note all the modules that occur are projective) of the canonical map for $H$, hence injective, hence bijective, so that $B$ is a quasi-Hopf algebra.

With essentially the same proof we can show:

**Theorem 6.5.** Let $H$ be a weak Hopf algebra, and $B = H/I$ a finite-dimensional quotient weak bialgebra (i.e. $I$ is a coideal and an ideal). The following are equivalent:

1. $B$ is a weak Hopf algebra.
2. The right $B$-module $B$ is isomorphic to the $B$-module $B$ obtained by restricting the left $B$-module $B$ along $\varepsilon$.

**7. Duality**

In [19, Sec.5] we have discussed a notion of skew pairing and duality suitable for $\times_R$-bialgebras. Let $R$ be a $k$-algebra and $H, \Lambda$ two $\times_R$-bialgebras. We have defined [19, Def.5.1] a skew pairing between $\Lambda$ and $H$ to be a $k$-linear map $\tau : \Lambda \otimes H \to R$ satisfying

\begin{align}
(r \otimes s)(t \otimes \tau)v &= r\tau(t)(t \otimes \tau)h(u \otimes \tau), \\
\tau(x(g)) &= \tau(x(h)(1))g(2), \\
\tau(\zeta(g)) &= \tau(\zeta(h)(1))g(2), \\
\tau(1, h) &= C(h)(1)
\end{align}

for all $r, s, t, u, v \in R, x, \zeta \in \Lambda$ and $g, h \in L$.

As pointed out in [19], it is essential that we define a skew pairing rather than a pairing in this situation. (An alternative chosen by Kadison and Szlachányi [9] is to consider pairings between “left” and “right” bialgebroids.)

For weak bialgebras it is no problem to define a Hopf algebra pairing, of course, though the problem for $\times_R$-bialgebras has its counterpart in the fact that the source counital subalgebra of the dual of a finite-dimensional weak bialgebra $H$ is canonically isomorphic to the target rather than the source counital subalgebra of $H$.

We define a skew pairing between weak bialgebras $\Lambda, H$ to be a linear map $\tau_0 : \Lambda \otimes H \to k$ satisfying

\begin{align}
\tau_0(x(g)) &= \tau_0(x(h)(1))g(2), \\
\tau_0(\zeta(g)) &= \tau_0(\zeta(h)(1))g(2), \\
\tau_0(1, h) &= C(h)(1)
\end{align}

for $x, \zeta \in \Lambda$ and $g, h \in H$.

For the rest of the section let $R$ be a Frobenius-separable algebra with idempotent Frobenius system $(\phi, e)$.

**Lemma 7.1.** Let $\Lambda, H$ be two $\times_R$-bialgebras.

If $\tau : \Lambda \otimes H \to R$ is a skew pairing of $\times_R$-bialgebras. Then $\tau_0 := \phi \tau : \Lambda \otimes H \to k$ is a skew pairing between the corresponding weak bialgebras.

**Proof.** We first note that $e^{(1)}h^{(1)} \otimes e^{(2)}h^{(2)} = h^{(1)} \otimes h^{(2)}$ holds in $H \otimes H$ for all $h \in H$ (and similar formulas for $\Lambda$), so that

\begin{align}
\tau(\zeta(h)(1))h(2) &= \phi(\tau(\zeta(h)(1))h(2))e^{(1)}h^{(2)} = \phi(\tau(\zeta(h)(1))h(2))e^{(2)}h^{(2)} = \tau_0(\zeta(h)(1))h(2)
\end{align}
for all $\zeta \in \Lambda$ and $h \in H$. It follows that

$$
\tau_0(\xi \zeta | h) = \phi \tau(\xi \zeta | h) = \phi(\tau(\xi | \tau(\zeta | h|_1)h|_2))
= \tau_0(\xi | \tau(\zeta | h|_1)h|_2)) = \tau_0(\xi | \tau_0(\zeta | h|_1)h|_2))
$$

for all $\xi, \zeta \in \Lambda$ and $h \in H$. Moreover

$$
\tau_0(1|h) = \phi \tau(1|h) = \phi(C(h)(1)) = \varepsilon(h).
$$

On the other side, using that $\xi$ is degenerate in its right argument by definition of $k$-dimensional over $H$.

By (7.1), a skew pairing between $\times_R$-bialgebras $\Lambda$ and $H$ defines a map $\Lambda \to \text{Hom}_{\mathcal{M}}(H, R)$. In the case that $H$ is finitely generated projective, there is a unique $\times_R$-bialgebra structure on $H^\vee := \text{Hom}_{\mathcal{M}}(H, R)$ such that evaluation defines a skew pairing $H^\vee \otimes H \to k$, see [19, Thm.5.13].

In our situation, where $R$ is Frobenius-separable, any $R$-module is projective, so $H$ is a finitely generated projective left $\mathcal{M}$-module if and only if $H$ is finite dimensional over $k$. Then the vector space dual $H^*$ of the weak bialgebra $H$ has a natural weak bialgebra structure, consisting of the usual dual algebra of the coalgebra $H$, and the dual coalgebra of the algebra $H$. Note that $(H^*)^{\text{op}}$ has a skew pairing with $H$.

**Proposition 7.2.** Let $H$ be a finite dimensional $\times_R$-bialgebra. Then the weak bialgebra corresponding to $H^\vee$ is the opposite $(H^*)^{\text{op}}$ of the dual $H^*$ of the weak bialgebra corresponding to $H$.

**Proof.** Evaluation of $H^\vee$ on $H$ defines a skew pairing of $\times_R$-bialgebras which is nondegenerate in its right argument by definition of $H^\vee$, and also in its left argument since $H$ is finitely generated projective as a left $R$-module.

We have seen that $\tau$ induces a skew pairing $\tau_0: H^\vee \otimes H \to k$ of weak bialgebras. It only remains to verify that $\tau_0$ is nondegenerate.

So let first $\xi \in H^\vee$, and assume that $\tau_0(\xi | h) = 0$ for all $h \in H$. Then for all $h \in H$ we have $0 = \phi(\tau(\xi | e^{(1)}h))e^{(2)} = \phi(\tau(\xi | h)e^{(1)})e^{(2)} = \tau(\xi | h)$ and hence $\xi = 0$ by definition of $H^\vee$.

By a parallel argument we can show that $\tau_0$ is nondegenerate in the left argument as well.

**Remark 7.3.** Let $(H, \Delta)$ be a finite-dimensional weak bialgebra with counital subalgebra $R$. Let $(H, \Gamma)$ be the associated $\times_R$-bialgebra. To distinguish, let $(H, \Delta)_M$ denote the category of left comodules over the ordinary $k$-coalgebra $H$, and let $(H, \Gamma)_M$ denote the category of left comodules over the $\times_R$-bialgebra $H$. By [19, Cor.5.15] one has an equivalence of monoidal categories $H^\vee \mathcal{M} \cong H^\vee \mathcal{M}$. By Proposition 5.3 and Proposition 7.2 we may replace $H^\vee \mathcal{M}$ by the module category $(H^*)^{\text{op}} \mathcal{M}$ over
the opposite of the dual weak bialgebra, which in turn is the comodule category 
\((H, \Delta) \mathcal{M}\) over the weak bialgebra \(H\). Combining, we have a category equivalence 
\((H, \Delta) \mathcal{M} \cong (H, \Gamma) \mathcal{M}\), which we will now derive more directly, and without using 
finiteness.

**Proposition 7.4.** Let \((H, \Delta)\) be a weak bialgebra, and \((H, \Gamma)\) the associated \(\times_R\)bialgebra.

1. Let \(M\) be a comodule over the \(\times_R\)-bialgebra \(H\), with comodule structure \(\lambda: M \ni m \mapsto m\}_{-1} \otimes m_{[0]} \in H \times_R M\). Then the underlying vector space of \(M\) is a left \(H\)-comodule over the \(k\)-coalgebra \(H\) with comodule structure 
\[\delta: M \ni m \mapsto e(1)m_{[0]} \otimes e(2)m_{[0]} \in H \otimes M.\]

2. Let \(M\) be a left \(H\)-comodule over the \(k\)-coalgebra \(H\), with comodule structure map \(\delta\). Then \(M\) is an \(R\)-bimodule by
\[ (7.4) \quad rms := \varepsilon(rm_{[-1]}s)m_{(0)}, \]
and a left \(H\)-comodule for the \(\times_R\)-bialgebra \(H\) with the comodule structure \(\lambda\) such that
\[ M \xrightarrow{\delta} H \times_R M \subset H \circ M \]
is the composition
\[ M \xrightarrow{\delta} H \otimes M \rightarrow H \circ M \]
in which the second map is the canonical epi.

The two constructions describe a bijection between the two types of comodule struc-
tures on a given \(k\)-vector space \(M\). In particular, one has a category equivalence 
\((H, \Delta) \mathcal{M} \cong (H, \Gamma) \mathcal{M}\).

**Proof.** If we assume that \(M\) is a comodule over the \(\times_R\)-bialgebra \(H\), then the calculation showing that it is a comodule over the coalgebra \(H\) as claimed in (1) is a spitting image of the proof that \(H\) is an ordinary coalgebra in Theorem 5.5.

So assume that \(M\) is a comodule over the ordinary coalgebra \(H\). The bimodule structure (7.4) was first defined by Nill [16, Prop.4.1] under the assumption that \(H\) is finite dimensional. As a first indication that the structure is appropriate, note that we have
\[ (7.5) \quad \varepsilon(rh_{(1)}s)h_{(2)} = rhs \]
for all \(r, s \in R\) and \(h \in H\) by (4.6). To see that (7.4) defines a bimodule structure, we only make a sample calculation, say of associativity of the left module structure:
\[ r(sm) = \varepsilon(sm_{[-1]}rm_{(0)}) = \varepsilon(sm_{[-2]}\varepsilon(rm_{[-1]})m_{(0)}) \]
\[ = \varepsilon(r\varepsilon(sm_{[-1]}(1))m_{[-1](2)}m_{(0)} \overset{(7.5)}{=} \varepsilon(r(sm_{[-1]}))m_{(0)} = (rs)m. \]
The calculation for associativity of the right \(R\)-module structure, and compatibility of the left and right module structures, are analogous.

Once we note now (compare [16, (4.24)]) that
\[ m_{(-1)}l_{(1)} \otimes m_{(0)}l_{(2)} = m_{(-2)}l_{(1)} \otimes \varepsilon(m_{(-1)}l_{(2)})m_{(0)} \]
\[ = (m_{(-1)}l_{(1)}\varepsilon(m_{(-1)}l_{(2)})) \otimes m_{(0)} = m_{(-1)} \otimes m_{(0)} \]
holds for \(m \in M\), the rest of the proof of (2) is again the same as the proof that \(H\) is a \(\times_R\)-bialgebra in Theorem 5.1.
We omit showing that the two constructions described in (1) and (2) are inverse to each other.

Remark 7.5. Using (4.8) in Remark 5.2, we can describe the tensor product of two left $H$-comodules $M$ and $N$, which is their tensor product $M \otimes_R N$, by the isomorphic subspace
\[ \{ \varepsilon(m(-1)n(-1))m(0) \otimes n(0) | m \in M, n \in N \} \subset M \otimes N \]
since we have
\[ me^{(1)} \otimes e^{(2)} n = \varepsilon(m(-1)\varepsilon(1(1))) \varepsilon(1(2)n(-1)) \otimes m(0) \otimes n(0) \]
\[ = \varepsilon(m(-1)1(1)) \varepsilon(1(2)n(-1)) m(0) \otimes n(0) = \varepsilon(m(-1)n(-1)) m(0) \otimes n(0). \]
for $m \in M$ and $n \in N$. Both versions of a tensor product in the category of $H$-comodules (the tensor product over $R$ and the version that is a subspace of the tensor product over $k$) were discussed and compared by Nill [16, Sec.4] in the case where $H$ is finite dimensional.
