Abstract

It is proposed to use the pinch technique to obtain the gauge-independent thermal $\beta$ function $\beta_T$ in a hot Yang-Mills gas. Calculations of $\beta_T$ are performed at one-loop level in four different gauges, (i) the background field method with an arbitrary gauge parameter, (ii) the Feynman gauge, (iii) the Coulomb gauge, and (iv) the temporal axial gauge. When the pinch contributions to the gluon self-energy are included, the same result is derived for $\beta_T$ in all four cases.

1 Introduction

It is important for the study of the quark-gluon plasma and/or the evolution of the early Universe to fully understand the behaviour of the effective coupling constant $\alpha_s(= g^2/4\pi)$ in QCD at high temperature. The running of $\alpha_s$ with the temperature $T$ and the external momentum $\kappa$ is governed by the thermal $\beta$ function $\beta_T$ [1]. However, the previous calculations of $\beta_T$ have exposed various problems: (i) strong vertex dependence—the coupling strongly depends on which vertex is chosen to renormalize $\alpha_s$ [2]-[4]; (ii) severe dependence on the vertex-momentum configuration even after a vertex is specified [5]; (iii) the gauge-fixing dependence [2]. To circumvent these difficulties, it was then proposed to use [6] the Vilkovisky-DeWitt effective action [7][8] or to use [9]-[11] the background field method (BFM) for the calculation of $\beta_T$ at one-loop. (In Yang-Mills theories the Vilkovisky-DeWitt effective action formalism coincides with BFM in the background Landau gauge [8].)

First introduced by DeWitt [12], BFM is a technique for quantizing gauge field theories while retaining explicit gauge invariance for the background fields. Since the Green’s functions constructed by BFM manifestly maintain gauge invariance, they obey the naive QED-like Ward-Takahashi identities and the renormalized gauge coupling is defined only through the gluon wave-function renormalization constant. As a result, when the static and symmetric point is chosen for the renormalization condition of the three-gluon vertex, $\beta_T$ is obtained in BFM from [6][9]-[11]

$$\beta_T \equiv T \frac{dg(T, \kappa)}{dT} = \frac{g}{2\kappa^2} T \frac{d\Pi_T(T, \kappa)}{dT}.$$  (1.1)

where $\Pi_T(T, \kappa) = \Pi_T(T, k_0 = 0, \kappa = |\vec{k}|)$ is the transverse function of the gluon self-energy $\Pi_{\mu\nu}$ at the static limit. Due to the $O(3)$ invariance, the spatial part of the gluon self-energy $\Pi_{ij}$ is expressed as follows:

$$\Pi_{ij}(k) = \Pi_T(\delta_{ij} - \frac{k_i k_j}{k^2}) + \Pi_L \frac{k_i k_j}{k^2}$$  (1.2)

and $\Pi_T$ can be extracted by applying the projection operator

$$t_{ij} = \frac{1}{2}(\delta_{ij} - \frac{k_i k_j}{k^2})$$  (1.3)
to $\Pi_{ij}$.

The thermal $\beta$ function has been calculated in BFM at one-loop level for the cases of the gauge parameter $\xi_Q = 0$ [6][10], $\xi_Q = 1$ [9] and $\xi_Q$ = an arbitrary number [11]. The results are expressed in a form,

$$\beta_{BFM}^T = g^3 N \left\{ \frac{7}{16} - \frac{1}{8} (1 - \xi_Q) + \frac{1}{64} (1 - \xi_Q)^2 \right\} \frac{T}{\kappa},$$

(1.4)

where $N$ is the number of colors. Contrary to the case of the QCD $\beta$ function at zero temperature, $\beta_{BFM}^T$ is dependent on the gauge-parameter $\xi_Q$. The reason why we have obtained $\xi_Q$-dependent $\beta_T$ in BFM is that the contributions to $\beta_T$ come from the finite part of the gluon self-energy $\Pi_{\mu\nu}$ and that BFM gives $\xi_Q$-dependent finite part for $\Pi_{\mu\nu}$. The latter notion had already been known [7][8] but was recently brought to light again in a different context [13][14].

The purpose of the present paper is to propose the use of the pinch technique (PT) to obtain the gauge-independent $\beta_T$ in a hot Yang-Mills gas. The preliminary results of this paper were given in Ref.[15]. The PT was proposed some time ago by Cornwall [16] for an algorithm to form new gauge-independent proper vertices and new propagators with gauge-independent self-energies. First it was used to obtain the one-loop gauge-independent effective gluon self-energy and vertices in QCD [17] and then it has been applied to the standard model [18]. The application of PT to QCD at high temperature was first made by Alexanian and Nair [19] to calculate the gap equation for the magnetic mass to one-loop order.

In the framework of PT, the one-loop gluon self-energy, when the one-loop pinch contributions from the vertex and box diagrams are added, becomes gauge-independent. In this way we can construct the gauge-independent effective gluon self-energy. As in the case of BFM, the effective gluon self-energy constructed by PT obey the naive QED-like Ward-Takahashi identity. Thus we can use the same Eq.(1.1) to calculate $\beta_T$ in the framework of PT. More importantly, PT gives the gauge-independent results up to the finite terms, since they are constructed from $S$-matrix. It was shown recently [20] that BFM with the gauge parameter $\xi_Q = 1$ reproduces the PT results at one-loop order. However, for $\xi_Q \neq 1$, this coincidence does not hold any more. In fact, BFM gives at one-loop order the gluon self-energy whose finite part is $\xi_Q$-dependent. Interestingly enough, Papavassiliou [13] showed
that when PT is applied to BFM for $\xi_Q \neq 1$ to construct the effective gluon self-energy, the gauge-parameter dependence of the finite part disappears and the previous $\xi_Q = 1$ result (or the universal PT result) is recovered. To author’s knowledge, there exists, so far, only one approach, i.e. PT, which gives the gauge-independent gluon self-energy including the finite terms. And indeed these finite terms give contributions to $\beta_T$. This notion inspires the use of PT for the calculations of $\beta_T$.

The paper is organized as follows. In the next section, we develop the general prescription necessary for extracting the pinch contributions to the gluon self-energy from the one-loop quark-quark scattering amplitude. Using this prescription, in Sect.3, we give the complete expressions of the one-loop pinch contributions calculated in four different gauges, (i) the BFM with an arbitrary gauge parameter, (ii) the Feynman gauge, (iii) the Coulomb gauge, and (iv) the temporal axial gauge. (The expressions given in Ref.[15] were enough for the calculation of $\beta_T$ but not in a complete form.) Then we show in detail that when two contributions to $\beta_T$ are added, one from the ordinary one-loop gluon self-energy and the other from “pinch” counterpart, we obtain the same $\beta_T$ in the above four different gauges. Sect.4 is devoted to the conclusions and discussions. In addition, we present two Appendices. In Appendix A, we give one-loop pinch contributions to the gluon self-energy from the vertex diagrams of the first kind, of the second kind and box diagrams, separately, in the above four different gauges. In Appendix B, we list the formulas for thermal one-loop integrals necessary for calculating $\beta_T$ in this paper.

2 Pinch technique

In this section we explain how to obtain the one-loop pinch contributions to the gluon self-energy. Let us consider the $S$-matrix element $T$ for the elastic quark-quark scattering at one-loop order in the Minkowski space, assuming that quarks have the same mass $m$. Besides the self-energy diagram in Fig.1, the vertex diagrams of the first kind and the second kind, and the box diagrams, which are shown in Fig.2(a), Fig.3(a), and Fig.4(a), respectively, contribute to $T$. Such contributions are, in general, gauge-dependent while the sum is gauge-independent. Then we
single out the “pinch parts” of the vertex and box diagrams, which are depicted in Fig.2(b), Fig.3(b), and Fig.4(b). They emerge when a $\gamma^\mu$ matrix on the quark line is contracted with a four-momentum $k_\mu$ offered by a gluon propagator or a bare three-gluon vertex. Such a term triggers an elementary Ward identity of the form
\[ k^\mu = (p^\mu + k^\mu - m) - (p^\mu - m). \] (2.1)
The first term removes (pinches out) the internal quark propagator, whereas the second term vanishes on shell, or vice versa. This procedure leads to contributions to $T$ with one or two less quark propagators and, hence, let us call these contributions as $T_P$, “pinch parts” of $T$.

Next we extract from $T_P$ the pinch contributions to the gluon self-energy $\Pi^{\mu\nu}$. First note that the contribution of the gluon self-energy diagram to $T$ is written in the form
\[ T^{(S.E)} = [T^a \gamma^\alpha] D_{\alpha\mu}(k) \Pi^{\alpha\beta}(k) [T^a \gamma^\beta], \] (2.2)
where $D(k)$ is a gluon propagator, $T^a$ is a representation matrix of $SU(N)$, and $\gamma^\alpha$ and $\gamma^\beta$ are $\gamma$ matrices on the external quark lines. The pinch contribution $\Pi^{\mu\nu}_P$ to $T_P$ should have the same form. Thus we must take away $[T^a \gamma^\alpha] D_{\alpha\mu}(k)$ and $D^{\nu\beta}(k) [T^a \gamma^\beta]$ from $T_P$. For that purpose we use the following identity satisfied by the gluon propagator and its inverse:
\[ g_\beta^\alpha = D_{\alpha\mu}(k) [D^{-1}]^\mu_\beta(k) = D_{\alpha\mu}(k) [-k^2 d^\mu_\beta] + k_\alpha \text{ term} \]
\[ = D^{-1}_{\alpha\mu}(k) D^\beta_\mu(k) = [-k^2 d_{\alpha\mu}] D^{\mu\beta}(k) + k_\beta \text{ term}, \] (2.3)
where
\[ d^{\mu\nu} = g^{\mu\nu} - \frac{k^\mu k^\nu}{k^2}. \] (2.4)
The $k_\alpha$ and $k_\beta$ terms give null results when they are contracted with $\gamma_\alpha$ and of $\gamma_\beta$, respectively, of the external quark lines.

The pinch part of the one-loop vertex diagrams of the first kind depicted in Fig.2(b) plus their mirror graphs has a form
\[ T^{(V_1)}_P = A [T^a \gamma^\alpha] D_{\alpha\beta}(k) [T^a \gamma^\beta], \] (2.5)
where $A$ (also $B_0$, $B_{ij}$, $C_0$, and $C_{ij}$ in the equations below) contains a loop integral. Using Eq.(2.3) we find
\[
\gamma^\alpha D_{\alpha\beta}(k)\gamma^\beta = \gamma^\alpha D_{\alpha\mu}(k)[-k^2 d^{\mu\nu}]D_{\nu\beta}(k)\gamma^\beta
\] (2.6)

Thus the contributions to $\Pi^{\mu\nu}$ from the vertex diagrams of the first kind are written as
\[
\Pi_{P}^{\mu\nu(V_1)} = [-k^2 d^{\mu\nu}]A
\] (2.7)

The pinch part of the one-loop vertex diagrams of the second kind depicted in Fig.3(b) plus their mirror graphs has a form
\[
T_P^{(V_2)} = \left[
T^a \left\{ [\gamma^\alpha] B_0 + \sum_{i,j} [\not{p}_i] p^\nu_j B_{ij} \right\} \right] D_{\kappa\beta}(k) \left[ T^a \gamma^\beta \right]
+ (\mu \leftrightarrow \nu),
\] (2.8)

where $(\mu \leftrightarrow \nu)$ terms are the contributions from mirror diagrams, and $p_i$ and $p_j$ are four-momenta appearing in the diagrams. Using Eq.(2.3) and
\[
[\not{p}_i] p^\kappa_j D_{\kappa\beta}(k) = [\gamma^\alpha] D_{\alpha\mu}(k)[-k^2 d^{\mu\lambda}] p_i^\lambda p^\nu_j D_{\nu\beta}(k),
\] (2.9)

we obtain for the contributions to $\Pi^{\mu\nu}$ from the vertex diagram of the second kind
\[
\Pi_{P}^{\mu\nu(V_2)} = [-k^2 d^{\mu\nu}]B_0 + [-k^2 d^{\mu\lambda}] \sum_{i,j} p_i^\lambda p^\nu_j B_{ij}
+ (\mu \leftrightarrow \nu).
\] (2.10)

The pinch part of the one-loop box diagrams depicted in Fig.4(b) has a form
\[
T_P^{(Box)} = \left[ T^a \left\{ [\gamma^\alpha][\gamma_{\alpha}] C_0 + \sum_{i,j} [\not{p}_i] [\not{p}_j] C_{ij} \right\} \right] T^a.
\] (2.11)

Again from Eq.(2.3) we see that $[\gamma^\alpha][\gamma_{\alpha}]$ and $[\not{p}_i][\not{p}_j]$ are rewritten as
\[
[\gamma^\alpha][\gamma_{\alpha}] = [\gamma^\alpha] D_{\alpha\mu}(k)[k^4 d^{\mu\nu}] D_{\nu\beta}(k)[\gamma^\beta]
\] (2.12)

and thus we obtain for the contributions to $\Pi^{\mu\nu}$ from the box diagrams
\[
\Pi_{P}^{\mu\nu(Box)} = [k^4 d^{\mu\nu}] C_0 + [k^4 d^{\mu\lambda} d^{\nu\tau}] \sum_{i,j} p_i^\lambda p^\nu_j C_{ij}.
\] (2.14)

It is observed that the prescription developed here is general and can be applied to the calculation of the one-loop pinch contributions in any gauge.
3 Calculation of Thermal $\beta$ Function

In this section it will be shown that we obtain the same $\beta_T$ in the framework of PT even when we calculate in four different gauges, (i) the background field method with an arbitrary gauge parameter, (ii) the Feynman gauge, (iii) the Coulomb gauge, and (iv) the temporal axial gauge. From now on we use the imaginary time formalism of thermal field theory. Thus the loop integral in the Minkowski space is replaced with the following one:

$$-i \int \frac{d^4p}{(2\pi)^4} \Rightarrow \int dp \equiv \int \frac{d^3p}{8\pi^3} T \sum_n,$$

where the summation goes over the integer $n$ in $p_0 = 2\pi inT$.

3.1 The Background Field Method

In the background field method (BFM) with an arbitrary gauge parameter $\xi_Q$, the gluon propagator $iD_{ab(BFM)}^{\mu\nu} = i\delta_{ab}D_{BFM}^{\mu\nu}$ and the three-gluon vertex $\tilde{\Gamma}_{abc}^{\lambda\mu\nu}$ with one background gluon field $A_{\mu}^b$ are given as follows [21]:

$$D_{(BFM)}^{\mu\nu} = -\frac{1}{k^2}\left[g^{\mu\nu} - (1 - \xi_Q)\frac{k^\mu k^\nu}{k^2}\right], \quad (3.2)$$

and

$$\tilde{\Gamma}_{\lambda\mu\nu}^{abc}(p, k, q) = gf^{abc}\left[(1 - \frac{1}{\xi_Q})\Gamma_{\lambda\mu\nu}^P(p, k, q) + \Gamma_{\lambda\mu\nu}^F(p, k, q)\right], \quad (3.3)$$

where

$$\Gamma_{\lambda\mu\nu}^P(p, k, q) = p_{\lambda}g_{\mu\nu} - q_{\nu}g_{\lambda\mu}$$

$$\Gamma_{\lambda\mu\nu}^F(p, k, q) = 2k_{\lambda}g_{\mu\nu} - 2q_{\nu}g_{\lambda\mu} - (2p + k)_{\mu}g_{\lambda\nu}, \quad (3.4)$$

and $f^{bac}$ is the structure constant of the group $SU(N)$. In the vertex, $k_{\mu}$ is taken to be the momentum of the background field and each momentum flows inward and, thus, $p + k + q = 0$.

The gluon self-energy at one-loop level was calculated in BFM with an arbitrary gauge parameter $\xi_Q$ [22] and is given as follows:

$$\Pi_{(BFM)}^{\mu\nu}(k) = N g^2 \int dp \left[ \frac{1}{p^2 q^2} (4p^\mu p^\nu - 2p^2 g^{\mu\nu} - k^\mu k^\nu + 4k^2 d^{\mu\nu}) \right]$$
\[-(1 - \xi_Q) \frac{k^2}{p^2 q^2} \{ (k^2 - q^2) d^{\mu \nu} + \left[ (d^{\mu \alpha} p_{\alpha} p' + d^{\nu \beta} p_{\beta} p') + (p \leftrightarrow q) \right] \}
+ \frac{1}{2} (1 - \xi_Q)^2 \frac{k^4}{p^4 q^4} d^{\mu \alpha} d^{\nu \beta} p_{\alpha} p_{\beta}, \]

(3.5)

where it is understood that the loop variables are related by \( k + p + q = 0 \).

The transverse function in the static limit, \( \Pi_{\beta_{BFCG}}^{BFG}(k_0 = 0, \kappa = |\vec{k}|) \), can be extracted by applying the projection operator \( t_{ij} \) to \( \Pi_{ij}^{B_{BFCG}}(k) \) and we have

\[
\Pi_{\beta_{BFCG}}^{BFG}(T, \kappa) = 2 N g^2 \int dp \frac{1}{p^2 q^2} \left[ p_0^2 + 2 \vec{k}^2 - \frac{(\vec{k} \cdot \vec{p})^2}{k^2} \right] 
+N g^2 (1 - \xi_Q) \int dp \left\{ \frac{\vec{k}^2}{p^2 q^2} + \frac{2}{p^2 q^2} \left[ -\vec{k}^2 (\vec{k} \cdot \vec{p}) + \vec{k}^2 \vec{p}^2 - (\vec{k} \cdot \vec{p})^2 \right] \right\}
+N g^2 (1 - \xi_Q)^2 \frac{2 \vec{k} \cdot \vec{p}}{p^2 q^2}.
\]

(3.6)

After the \( p_0 \) summation and the angular integration we obtain

\[
\Pi_{\beta_{BFCG}}^{BFG}(T, \kappa) = \frac{N g^2}{4 \pi^2} \int_0^\infty dp \, p \, n(p) \left\{ -2 + \frac{2p}{\kappa} \ln \left[ \frac{2p + \kappa}{2p - \kappa} \right] \right. 
- N g^2 (1 - \xi_Q) \frac{\kappa}{4 \pi^2} \int_0^\infty dp \, p \, n(p) \left\{ -\frac{4p \kappa}{(2p + \kappa)(2p - \kappa)} + \ln \left[ \frac{2p + \kappa}{2p - \kappa} \right] \right\}
+N g^2 (1 - \xi_Q)^2 \frac{\kappa}{4 \pi^2} \int_0^\infty dp \, p \, n(p) \left\{ \frac{2 \kappa^2}{(2p + \kappa)(2p - \kappa)} + \frac{\kappa}{2p} \ln \left[ \frac{2p + \kappa}{2p - \kappa} \right] \right\}
\]

(3.7)

where, in the r.h.s., \( p \equiv |\vec{p}| \), distribution function, and we have used formulas given in Appendix B for the thermal one-loop integrals. Also listed in Appendix B are the formulas useful for the \( \kappa << T \) expansion. In the limit \( \kappa << T \) we get

\[
\Pi_{\beta_{BFCG}}^{BFG}(T, \kappa) \approx N g^2 \kappa T \left\{ \frac{7}{16} - \frac{1}{8} (1 - \xi_Q) + \frac{1}{64} (1 - \xi_Q)^2 \right\} + O(\kappa^2).
\]

(3.8)

Using this expression for \( \Pi_T \) in Eq. (1.1), Elmfors and Kobes obtained Eq. (1.4) for \( \beta_{BFCG}^{BFG} \) which is indeed gauge-parameter \( \xi_Q \) dependent [11].

Now we evaluate the pinch contributions to \( \Pi_T \). We consider the quark-quark scattering at one-loop order, using the gluon propagator and the three-gluon vertex.
given in Eqs.(3.2)-(3.4). We pinch out the internal quark propagators and obtain the pinch parts of the scattering amplitude \( T_P \). Since the inverse of the propagator \( D^{-1}_{(BFM)}(k) \) is given by

\[
[D^{-1}_{(BFM)}]^{\mu\nu}(k) = -k^2 \left[ g^{\mu\nu} - \left( 1 - \frac{1}{\xi_Q} \right) \frac{k^\mu k^\nu}{k^2} \right],
\]

(3.9)

\( D_{(BFM)} \) and \( D^{-1}_{(BFM)} \) satisfy the relations in Eq.(2.3)

\[
D_{(BFM)} \alpha^\mu(k)[D^{-1}_{(BFM)} \mu^\beta](k) = [D_{(BFM)} \alpha^\mu(k)] \frac{k^\alpha k^\beta}{k^2} \]

(3.10)

Thus we can follow the prescription explained in Sect.2 and extract the pinch contributions to the gluon self-energy from \( T_P \). The sum is expressed as

\[
\Pi_{P(BFM)}^{\mu\nu}(k) = Ng^2 \left[ (1 - \xi_Q) k^2 d^{\mu\nu} \int \frac{dp}{p^4 q^2} \left( \frac{2}{p^4 q^2} k \cdot p \right) \right] + \frac{1}{2} (1 - \xi_Q)^2 k^4 d^{\mu\alpha} d^{\nu\beta} \int \frac{dp}{p^4 q^4} \left( \frac{k^2}{p^4} \right),
\]

(3.11)

which was first obtained by Papavassiliou [13]. For completeness the one-loop pinch contributions in BFM from the vertex diagrams of the first kind [Fig.2(b) and its mirror graph], the vertex diagrams of the second kind [Fig.3(b) and its mirror graph] and the box-diagrams [Fig.4(b)] are separately given in Appendix A.

Applying the projection operator \( t_{ij} \) to the spatial part of \( \Pi_{P(BFG)}^{\mu\nu}(k_0 = 0, \kappa = |\vec{k}|) \), we obtain

\[
\Pi_{T(BFM)}^{P(BFM)}(T, \kappa) = N g^2 (1 - \xi_Q) \kappa^2 \int dp \frac{2 \vec{k} \cdot \vec{p}}{p^4 q^2} \left( \frac{1}{p^4 q^2} \right) \]

\[
- \frac{N}{4} g^2 (1 - \xi_Q)^2 \kappa^2 \int dp \frac{\vec{k}^2 \vec{p}^2 - (\vec{k} \cdot \vec{p})^2}{p^4 q^4}.
\]

(3.12)

Clearly, the \((1 - \xi_Q)^2\) terms of \( \Pi_T^{(BFM)} \) in Eq.(3.10) and of \( \Pi_T^{P(BFM)} \) in Eq.(3.12) are the same but have an opposite sign, and so when they are combined they are cancelled out. Also we can see the \((1 - \xi_Q)\) terms of \( \Pi_T^{(BFM)} \) and of \( \Pi_T^{P(BFM)} \) cancel when combined, due to the identity

\[
\int dp \frac{\vec{k}^2 \vec{p}^2 - (\vec{k} \cdot \vec{p})^2}{p^4 q^2} = -\frac{1}{2} \vec{k}^2 \int dp \frac{1}{p^4 q^2}.
\]

(3.13)
Thus we find the sum

\[ \Pi_T(T, \kappa) \equiv \Pi_T^{(BFM)}(T, \kappa) + \Pi_T^{(BFM)}(T, \kappa) \]
\[ = \frac{Ng^2}{4\pi^2} \int_0^\infty dp \, p \, n(p) \left[ -2 + \left( \frac{2p}{\kappa} + \frac{7\kappa}{2p} \right) \ln \left( \frac{2p + \kappa}{2p - \kappa} \right) \right] \quad (3.14) \]

is gauge-parameter \( \xi_Q \) independent. In the limit \( \kappa \ll T \)

\[ \Pi_T(T, \kappa) \approx Ng^2 \kappa T \frac{7}{16} + O(\kappa^2) \quad (3.15) \]

and this gives a \( \xi_Q \)-independent thermal \( \beta \) function

\[ \beta_T = g^3 N \frac{7}{32} \frac{T}{\kappa} \quad (3.16) \]

Actually we will see below that the expression is independent of the choice of gauge-fixing. Note that the result coincides with \( \beta_T^{BFM} \) in Eq.(1.4) with \( \xi_Q = 1 \).

It should be remarked that not only the sum of \( \Pi_T^{(BFM)} \) and \( \Pi_T^{(BFM)} \), but also the sum of the one-loop gluon self-energy \( \Pi_T^{\mu\nu}(BFM)(k) \) and the corresponding pinch contribution \( \Pi_T^{\mu\nu}(BFM)(k) \) becomes \( \xi_Q \)-independent [13]. Indeed the \((1 - \xi_Q)\) term of \( \Pi_T^{\mu\nu}(BFM)(k) \) in Eq.(3.5) can be rewritten as

\[ Ng^2 (1 - \xi_Q) k^2 d^{\mu\nu} \int \frac{dp}{p^2 q^2} \quad (3.17) \]

with the help of the identity

\[ \int dp \frac{4p_\mu p_\nu}{p^4 q^2} = \int dp \frac{g_\mu\nu}{p^2 q^2} - \int dp \frac{2k_\mu p_\nu}{p^4 q^2}, \quad (3.18) \]

where \( p + q + k = 0 \) is understood and

\[ d_{\mu\alpha} \int dp \frac{p_\alpha}{p^4 q^2} = 0. \quad (3.19) \]

Thus both the \((1 - \xi_Q)\) and \((1 - \xi_Q)^2\) terms of \( \Pi_T^{\mu\nu}(BFM)(k) \) in Eq.(3.5) cancel out with the corresponding ones in \( \Pi_T^{\mu\nu}(BFM)(k) \) in Eq.(3.11) and there remains the \( \xi_Q \) independent (actually it is independent of the choice of gauge-fixing [23]) expression for the effective gluon self-energy,

\[ \hat{\Pi}^{\mu\nu}(k) = Ng^2 \int dp \frac{1}{p^2 q^2} \left( 4p_\mu p_\nu - 2p^2 g^{\mu\nu} - k^\mu k^\nu + 4k^2 d^{\mu\nu} \right). \quad (3.20) \]
Of course we can get the result of Eq. (3.14) directly by applying $t_{ij}$ to the above $\hat{\Pi}^{\mu\nu}(k)$ and by integration.

It is amusing to note that in BFM with the choice of $\xi_Q = 1$ there is no pinch contribution to the gluon self-energy at one-loop order. This is due to the fact with $\xi_Q = 1$ the longitudinal term $k_\mu k_\nu$ of the gauge boson propagator disappears and the three-gluon vertex $\bar{\Gamma}^{abc}_{\lambda\mu\nu}$ is made up of only $\Gamma^F_{\lambda\mu\nu}$ and, hence, there appears no four-momentum which triggers the Ward identity of Eq. (2.1) and pinches out a quark propagator. Therefore when we work with the choice of $\xi_Q = 1$ in BFM and calculate the gluon self-energy diagrams, we directly obtain the the gauge-independent expression $\hat{\Pi}^{\mu\nu}(k)$ in Eq. (3.20) [20].

### 3.2 The Feynman Gauge

In the Feynman gauge (FG) (the covariant gauge with $\xi = 1$) the gluon propagator, $iD^{\mu\nu}_{ab(FG)} = i\delta_{ab}D^{\mu\nu}_{(FG)}$, has a very simple form

$$D^{\mu\nu}_{(FG)}(k) = \frac{-1}{k^2}g^{\mu\nu}, \quad (3.21)$$

and the three-gluon vertex is expressed as

$$\Gamma^{abc}_{\lambda\mu\nu}(p, k, q) = g f^{bac}[\Gamma^P_{\lambda\mu\nu}(p, k, q) + \Gamma^F_{\lambda\mu\nu}(p, k, q)] \quad (3.22)$$

where $\Gamma^P_{\lambda\mu\nu}(p, k, q)$ and $\Gamma^F_{\lambda\mu\nu}(p, k, q)$ are given in Eq. (3.4). The expression of the one-loop gluon self-energy in FG is well known:

$$\Pi_{(FG)}^{\mu\nu}(k) = N g^2 \int \frac{1}{p^2 q^2} \left[ 4p^\mu p^\nu - 2p^2 g^{\mu\nu} - k^\mu k^\nu + 2k^2 d^{\mu\nu} \right]. \quad (3.23)$$

Since the inverse of the gluon propagator is given by

$$[D_{(FG)}^{-1}]^{\mu\nu}(k) = -k^2 g^{\mu\nu}, \quad (3.24)$$

$D_{(FG)}$ and its inverse satisfy

$$D^{(FG)}_{\alpha\mu}(k)[D_{(FG)}^{-1}]^{\mu\beta}(k) = D^{(FG)}_{\alpha\mu}(k)[-k^2 d^{\mu\beta}] + \frac{k_\alpha k^\beta}{k^2}$$

$$D^{-1}_{(FG)\alpha\mu}(k)D^{\mu\beta}_{(FG)}(k) = [-k^2 d_{\alpha\mu}]D^{\mu\beta}_{(FG)}(k) + \frac{k_\alpha k^\beta}{k^2}. \quad (3.25)$$
Then we follow the prescription explained in Sect. 2 and we obtain the pinch contributions to the gluon self-energy. Since the gluon propagator in FG does not have a longitudinal $k^\mu k^\nu$ term, the only contribution is coming from the vertex diagram of the second kind with the three-gluon vertex $\Gamma^P$ (and its mirror graph) [17], and it is given by

$$\Pi_{P(FG)}^{\mu\nu}(k) = 2Ng^2k^2d^{\mu\nu}\int dp\frac{1}{p^2q^2}.$$  \hspace{3.5cm}(3.26)

Adding $\Pi_{(FG)}^{\mu\nu}$ and $\Pi_{P(FG)}^{\mu\nu}$, we find the sum coincides with the gauge independent $\hat{\Pi}_{\mu\nu}^{(k)}$ in Eq.(3.20). Thus we obtain the same $\Pi_T$ in Eq.(3.15) and the same $\beta_T$ in Eq.(3.16) while we work in FG.

### 3.3 The Coulomb Gauge

In fact it is rather anticipated that once we use PT for the one-loop calculation of the thermal $\beta$ function, we obtain the $\xi_Q$-independent $\beta_T$ in BFM which coincides with the result in FG. However, it is less trivial whether we may reach the same result for $\beta_T$ when we calculate in noncovariant gauges such as the Coulomb gauge and the temporal axial gauge. We show in this and the following subsections that we indeed obtain the same $\beta_T$ in the above two noncovariant gauges when we use PT.

Given a unit vector $n^\mu = (1, 0, 0, 0)$, the gluon propagator in the Coulomb gauge (CG), $iD_{ab(CG)}^{\mu\nu} = i\delta_{ab}D_{(CG)}^{\mu\nu}$, and its inverse are expressed as

$$D_{(CG)}^{\mu\nu}(k) = -\frac{1}{k^2}\left[g^{\mu\nu} + \left(1 - \xi_C\frac{k^2}{k^2}\right)\frac{k^\mu k^\nu}{k^2} - \frac{k_0}{k^2}(k^\mu n^\nu + n^\mu k^\nu)\right]$$ \hspace{3.5cm}(3.27)

$$[D_{(CG)}^{-1}]^{\mu\nu}(k) = -k^2\left[g^{\mu\nu} - \frac{k^\mu k^\nu}{k^2}\right] + \frac{1}{\xi_C}\left[k^\mu k^\nu - k_0(k^\mu n^\nu + n^\mu k^\nu) + k_0^2n^\mu n^\nu\right].$$

where $\xi_C$ is the gauge parameter of CG. The three-gluon vertex is the same as in FG, that is, $\Gamma_{\lambda\mu\nu}^{abc}(p, k, q)$ in Eq.(3.22). It is noted that although in the limit $\xi_C = 0$, $D_{(CG)}^{\mu\nu}(k)$ reduces to the well-known form [24]

$$D^{00}_{(CG)} = \frac{1}{k^2}, \quad D^{0i}_{(CG)} = 0, \quad D^{ij}_{(CG)} = \frac{1}{k^2}\left(\delta^{ij} - \frac{k^i k^j}{k^2}\right),$$ \hspace{3.5cm}(3.28)
its inverse does not exist in this limit. In the framework of PT, we need to use the identities in Eq.(2.3), satisfied by the gluon propagator and its inverse, to extract from $T_P$ the pinch contributions to the gluon self-energy. Thus in principle we must work with a non-zero $\xi_C$. Then at one-loop level there appear $\xi_C$-dependent terms in the gluon self-energy. We can show [23], however, that the one-loop pinch contributions are also $\xi_C$-dependent and these $\xi_C$-dependent parts exactly cancel against the $\xi_C$-dependent terms in the self-energy. For our purpose of calculating the thermal $\beta$ function, therefore, it is enough to know the information on the $\xi_C$-independent part of both the self-energy and the pinch contributions. The $\xi_C$-independent part of the one-loop gluon self-energy was calculated in Ref.[25] using the gluon propagator in the $\xi_C = 0$ limit given in Eq.(3.28).

The transverse function $\Pi_T$ is related to the self-energy as

$$\Pi_T = t_{ij} \Pi_{ij} = \frac{1}{2} \left[ \Pi_{ii} - \frac{1}{k^2} k_i k_j \right].$$

(3.29)

Since $k_i k_j = 0$ in the static limit $k_0 = 0$, we have $\Pi_T(T, \kappa) = \frac{1}{2} \Pi_{ii}(k_0 = 0, \kappa)$. The $\xi_C$-independent part of $\Pi_{ii}^{(CG)}(k)$ is given in Eq.(4.12) of Ref.[25] as

$$\Pi_{ii}^{(CG)}(k) = \frac{N g^2}{2} \int dp \, p \, n(p) \left\{ \frac{3}{2} - \frac{5k^2}{4p^2} + \left[ -\frac{p}{4\kappa} - \frac{11\kappa}{8p} + \frac{k^3}{2p^3} + \frac{k^5}{8p^5} \right] \ln \left| \frac{p + \kappa}{p - \kappa} \right| + \left[ \frac{2p}{\kappa} + \frac{5\kappa}{2p} - \frac{k^3}{2p^3} - \frac{k^5}{16p^5} \right] \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \right\}.$$

(3.30)

Using the formulas given in Appendix B, we can calculate the static limit of $\Pi_{ii}^{CG}$ and we obtain

$$\Pi_T^{(CG)}(T, \kappa) = \frac{1}{2} \Pi_{ii}^{(CG)}(k_0 = 0, \kappa)$$

$$= \frac{Ng^2}{4\pi^2} \int_0^\infty dp \, p \, n(p) \left\{ \frac{3}{2} + \frac{5k^2}{4p^2} + \left[ -\frac{p}{4\kappa} - \frac{11\kappa}{8p} + \frac{k^3}{2p^3} + \frac{k^5}{8p^5} \right] \ln \left| \frac{p + \kappa}{p - \kappa} \right| + \left[ \frac{2p}{\kappa} + \frac{5\kappa}{2p} - \frac{k^3}{2p^3} - \frac{k^5}{16p^5} \right] \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \right\}$$

(3.31)

In the limit $\kappa << T$, this gives $\Pi_T^{(CG)}(T, \kappa) \approx Ng^2\kappa T_{\frac{9}{64}} + O(\kappa^2)$. 

12
Now we calculate the pinch contributions to the gluon self-energy in CG. Since the gluon propagator and its inverse satisfy the relations in Eq. (2.3), that is,

\[
D^{(CG)}_{(CG)\alpha\mu}(k)D_{(CG)\mu\beta}^{-1}(k) = D^{(CG)}_{(CG)\alpha\mu}(k)\left[-k^2d^{\mu\beta}\right] + \frac{k_\alpha}{k^2}(k_\alpha n^\beta - k^\beta)
\]

\[
D_{(CG)\alpha\mu}(k)D^{(CG)}_{(CG)\mu\beta}(k) = [-k^2d_{\alpha\mu}]D^{(CG)}_{(CG)\mu\beta}(k) + (k_\alpha n_\beta - k_\beta)\frac{k_\beta}{k^2}, \quad (3.32)
\]

gain we can follow the prescription explained in Sec. 2 to extract the one-loop pinch contributions. The individual contributions in CG from the vertex diagrams of the first kind, of the second kind and the box diagrams are presented in Appendix A.

In total we obtain for the $\xi_C$-independent part

\[
\Pi_{P(CG)}^{\mu\nu}(k) = \frac{N}{2}g^2k^2d^{\mu\alpha}\int \frac{dp}{p^2q^2p^2q^2}\left\{p_\alpha p_\beta(k^2 - 4q^2 + 2k^2)
\right.
\]
\[
\left.\ + (p_\alpha n_\beta + n_\alpha p_\beta)[p^2q_0 - q^2p_0 - 2\vec{p} \cdot \vec{q}(p_0 - q_0)] + n_\alpha n_\beta 4p_0q_0(pq)\right\}
\]
\[
+ \frac{N}{2}g^2\int d^{\mu\alpha}\left\{p_\alpha k^\nu \left[\frac{1}{q^2\vec{p}^2} - \frac{1}{p^2q^2} + \frac{1}{q^2} - \frac{1}{p^2}\right]\frac{\vec{p} \cdot \vec{q}}{p^2q^2q^2q^2}\right.
\]
\[
\left.\ + n_\alpha k^\nu \left[-\frac{q_0}{p^2q^2} + \frac{p_0}{q^2\vec{p}^2} + \frac{q_0}{p^2} + \frac{p_0}{q^2} + \frac{\vec{p} \cdot \vec{q}}{p^2q^2q^2}\right]\right\} + \mu \leftrightarrow \nu \right. \quad (3.33)
\]

It was pointed out [23] that the gluon self-energy calculated in CG does not satisfy the transversality relation, i.e., $\Pi^{\mu\nu}_{P(CG)}k_\nu \neq 0$. Now we can see that the pinch contribution $\Pi^{\mu\nu}_{P(CG)}$ does not satisfy the transversality relation either. In fact we get

\[
\Pi^{\mu\nu}_{P(CG)}k_\nu = \frac{N}{2}g^2k^2d^{\mu\alpha}\int \frac{dp}{p^2q^2p^2q^2}\left\{p_\alpha \left[\frac{1}{q^2\vec{p}^2} - \frac{1}{p^2q^2} + \frac{1}{q^2} - \frac{1}{p^2}\right]\frac{\vec{p} \cdot \vec{q}}{p^2q^2}\right.
\]
\[
\left.\ + n_\alpha \left[-\frac{q_0}{p^2q^2} + \frac{p_0}{q^2\vec{p}^2} + \frac{q_0}{p^2} + \frac{p_0}{q^2} + \frac{\vec{p} \cdot \vec{q}}{p^2q^2}\right]\right\}. \quad (3.34)
\]

It can be shown that this non-transverse part of pinch contribution exactly cancels against the non-transverse part of $\Pi^{\mu\nu}_{P(CG)}k_\nu$ and that the sum of $\Pi^{\mu\nu}_{(CG)}$ and $\Pi^{\mu\nu}_{P(CG)}$ indeed satisfies the transversality relation [23].

The function $\Pi^{(CG)}_{P(T)}(T, \kappa)$ is obtained by applying the projection operator $t_{ij}$ to the spatial part of $\Pi^{ij}_{P(CG)}(k_0 = 0, \kappa)$. Since $d^{\alpha\alpha}n_\alpha = 0$ in the static limit and
t_{ij}k^j = 0$, the terms proportional to $(p_\alpha n_\beta + n_\alpha p_\beta)$, $n_\alpha n_\beta$, $d^{\mu\alpha}p_\alpha k^\nu$ and $d^{\mu\alpha}n_\alpha k^\nu$ in Eq.\((3.33)\) do not contribute to $\Pi_T^{P\,(CG)}$. The result is

$$\Pi_T^{P\,(CG)}(T, \kappa) = -N g^2 \kappa^2 \int dp \left\{ \frac{1}{q^2-p^2} + \frac{2\vec{k} \cdot \vec{p}}{p^2 q^2 - \vec{p}^2} \right\} \right.$$ \[ - \frac{N}{4} g^2 \kappa^2 \int dp \left[ 1 - \frac{(\vec{k} \cdot \vec{p})^2}{\vec{k}^2 \vec{p}^2} \right] \left\{ \frac{\vec{k}^2}{p^2 q^2 - \vec{p}^2} - \frac{4}{p^2 q^2} \right\}. \tag{3.35} \]

Since the terms proportional to $n$ and $k$ do not contribute, the quickest way to arrive at the above expression of $\Pi_T^{P\,(CG)}$ is that we consider the quark-quark scattering amplitude at one-loop order and discard the terms which are proportional to $n$ and $k$ from the beginning. In fact, this simplified method was used in Ref.\([15]\) to obtain the pinch contribution $\Pi_T^p$ in both the Coulomb gauge and the temporal axial gauge.

After the $p_0$ summation and the angular integration for $\Pi_T^{P\,(CG)}$ (see the formulas listed in Appendix B), we have

$$\Pi_T^{P\,(CG)}(T, \kappa) = \frac{Ng^2}{4\pi^2} \int_0^\infty dp \, p \, n(p) \left\{ -\frac{1}{2} - \frac{5\kappa^2}{4p^2} + \left[ \frac{p}{4\kappa} + \frac{11\kappa}{8p} - \frac{\kappa^3}{2p^3} - \frac{\kappa^5}{8p^5} \right] \ln \left| \frac{p + \kappa}{p - \kappa} \right| \right.$$ \[ + \left[ \frac{\kappa^3}{p} + \frac{\kappa^5}{2p^3} + \frac{\kappa^5}{16p^5} \right] \ln \left| \frac{2p + \kappa}{2p - \kappa} \right] \}. \tag{3.36} \]

In the limit $\kappa \ll T$, this gives $\Pi_T^{P\,(CG)}(T, \kappa) \approx Ng^2 \kappa T^\frac{10}{64} + O(\kappa^2)$. Adding the two contributions, $\Pi_T^{(CG)}$ and $\Pi_T^{P\,(CG)}$, we find that the sum is equal to $\Pi_T$ in Eq.\((3.14)\) and, thus, we obtain the same $\beta_T$ in Eq.\((3.16)\).

### 3.4 The Temporal Axial Gauge

The gluon propagator in the temporal axial gauge (TAG), $iD^\mu\nu_{ab(T\,AG)}(T) = i\delta_{ab} D^\mu\nu_{(T\,AG)}$, and its inverse are defined by

$$D^\mu\nu_{(T\,AG)}(k) = -\frac{1}{k^2} \left[ g^\mu\nu + (1 + \xi_A k^2) \frac{k^\mu k^\nu}{k_0^2} - \frac{1}{k_0} (k^\mu n^\nu + n^\mu k^\nu) \right] \tag{3.37} \]

$$[D^{-1}_{(T\,AG)}]^\mu\nu(k) = -k^2 \left( g^\mu\nu - \frac{k^\mu k^\nu}{k^2} \right) - \frac{1}{\xi_A} n^\mu n^\nu \tag{3.38} \]
where $n^\mu = (1, 0, 0, 0)$. It is noted that the gauge parameter $\xi_A$ in TAG has a dimension of mass$^{-2}$. They satisfy the relations in Eq.(2.3):

$$D^{(T\,AG)}_{\alpha\mu}(k)[D^{-1}_{(T\,AG)}]_{\beta\mu}(k) = D^{(T\,AG)}_{\alpha\mu}(k)[-k^2d^{\mu\beta}] + k_\alpha\left(\frac{n_\beta}{k_0} - \frac{k_\beta}{k^2}\right)$$

$$D^{-1}_{(T\,AG)\alpha\mu}(k)D^{\mu\beta}_{(T\,AG)}(k) = [-k^2d_{\alpha\mu}]D^{\mu\beta}_{(T\,AG)}(k) + \left(\frac{n_\alpha}{k_0} - \frac{k_\alpha}{k^2}\right)k^\beta.$$ (3.39)

The three-gluon vertex is given by $\Gamma^{abc}_{\lambda\mu\nu}(p, k, q)$ in Eq.(3.22).

In the limit $\xi_A = 0$ the inverse of the gluon propagator does not exist. So in the framework of PT we must work with a non-zero $\xi_A$. Then $\xi_A$-dependent terms appear from both the one-loop gluon self-energy and the corresponding pinch contributions. But again they cancel each other [23]. So we only concern about the $\xi_A$-independent parts of the one-loop gluon self-energy and pinch contributions. It is noted that although the ghost field decouples in the limit $\xi_A = 0$, for a non-zero $\xi_A$ the ghost should be taken into account and at one-loop level it contributes to the $\xi_A$-independent part of $\Pi^{(T\,AG)}_{00}$ [23].

Using the TAG propagator with $\xi_A = 0$, the $\xi_A$-independent part of $\Pi^{(T\,AG)}_{ii}$ at one-loop was calculated in Ref.[23]. The static limit of $\Pi^{(T\,AG)}_{ii}$ for $\kappa << T$ was given in Eq.(4.44) of Ref. [23] as

$$\Pi^{(T\,AG)}_{ii}(k_0 = 0, \kappa) \approx Ng^2\kappa T^\frac{5}{8} + O(\kappa^2).$$ (3.40)

from which we obtain

$$\Pi^{(T\,AG)}_T(T, \kappa) = \frac{1}{2}\Pi^{(T\,AG)}_{ii}(0, \kappa) \approx Ng^2\kappa T^\frac{5}{16} + O(\kappa^2).$$ (3.41)

In Ref.[17] the pinch contribution to $\Pi_T(T, \kappa)$ in TAG was calculated and the result was for $\kappa << T$

$$\Pi^{P(T\,AG)}_T(T, \kappa) \approx Ng^2\kappa T\frac{1}{8} + O(\kappa^2).$$ (3.42)

Again the sum of $\Pi^{(T\,AG)}_T$ and $\Pi^{P(T\,AG)}_T$ coincides with $\Pi_T$ in Eq.(3.15) and yields the same $\beta_T$ in Eq.(3.16).

In the evaluation of $\Pi^{(T\,AG)}_{ii}(k_0 = 0, \kappa)$ and $\Pi^{P(T\,AG)}_T(T, \kappa)$, there appear $\vec{k}^2/\vec{p}^2$ singularities at the lower limit of the integration, due to the $1/p_0^2$ and $1/q_0^2$ terms
coming from the TAG propagator. These singularities were circumvented \cite{25,15} by the principal value prescription \cite{26}. In the present paper we show instead that when the pinch contributions are added to $\Pi^{TAG}_T(T, \kappa)$ before the $p(=|\vec{p}|)$-integration, these $\vec{k}^2/\vec{p}^2$ singularities cancel and the limit $p \to 0$ becomes regular, so that we can evaluate the sum of $\Pi^{TAG}_T$ and $\Pi^{P(TAG)}_T$ without recourse to the principal value prescription. In fact Eq. (4.43) for $\Pi^{TAG}_{ii}(0, \kappa)$ in Ref.\cite{25} will be rewritten as

$$\Pi^{TAG}_{ii}(0, \kappa) = \frac{Ng^2}{2\pi^2} \int_0^{\infty} dp \, p \, n(p) \times \left[ -2 + \frac{\kappa^2}{p^2} + \frac{\kappa^4}{4p^4} + \left( \frac{2p}{\kappa} + \frac{5\kappa^3}{2p^3} - \frac{\kappa^5}{16p^5} \right) \ln \left( \frac{2p + \kappa}{2p - \kappa} \right) \right] \ldots (3.43)$$

if we do not apply the principal value prescription. We see that the integrand (the terms in $\ldots$) will behave as $-4\kappa^2/3p^2$ for small $p$.

Since the TAG propagator and its inverse satisfy the relation of Eq. (2.3), we can follow the same procedure as before and we obtain for the $\xi_A$-independent part of the pinch contribution to the gluon self-energy in TAG,

$$\Pi_{\mu\nu}^{P(TAG)} = Ng^2 k^2 d^{\mu\nu} \int dp \, \frac{1}{p^2 q^2 p^2_0} \left( k^2 + 2p^2 - q^2 - 4\vec{k} \cdot \vec{p} \right)$$

$$+ \frac{N}{2} g^2 k^2 d^{\mu\nu} d^{\rho\sigma} \int dp \, \frac{1}{p^2 q^2 p^2 q^0} \left( p_\alpha p_\beta (k^2 - 4q^2 + 2\vec{k}^2) \right.$$

$$+(p_\alpha n_\beta + n_\alpha p_\beta) [-p^2 q_0 + q^2 p_0 - 2\vec{p} \cdot \vec{q}(p_0 - q_0)] + n_\alpha n_\beta 4p_0 q_0 (pq) \right) \ldots (3.44)$$

Then in the static limit, $\Pi^{P(TAG)}_T$ is expressed as

$$\Pi^{P(TAG)}_T(T, \kappa) = -Ng^2 k^2 \int dp \left\{ \frac{\vec{k}^2 + 4\vec{k} \cdot \vec{p}}{p^2 q^2 p^2_0} + \frac{1}{p^2 p^2_0} - \frac{2}{q^2 p^2} \right\}$$

$$- \frac{N}{4} g^2 k^2 \int dp \left\{ \vec{p}^2 - \frac{(\vec{k} \cdot \vec{p})^2}{\vec{k}^2} \right\} \left\{ \frac{\vec{k}^2}{p^2 q^2 p^2 q^0} - \frac{4}{p^2 q^2 p^2_0} \right\}. \ldots (3.45)$$

where the terms proportional to $(p_\alpha n_\beta + n_\alpha p_\beta)$ and $n_\alpha n_\beta$ in $\Pi^{\mu\nu}_{P(TAG)}$ do not contribute to $\Pi^{P(TAG)}_T$. After the $p_0$-summation and the angular integration, $\Pi^{P(TAG)}_T(T, \kappa)$ is
rewritten as
\[
\Pi^{P(TAG)}_T(0, \kappa) = \frac{Ng^2}{4\pi^2} \int_0^\infty dp \ p \ n(p) \\
\times \left[ -\frac{\kappa^2}{p^2} - \frac{\kappa^4}{4p^4} + \left( \frac{\kappa}{p} + \frac{\kappa^3}{2p^3} + \frac{\kappa^5}{16p^5} \right) \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \right],
\]
(3.46)
where we have used formulas given in Appendix B. Note that the integrand behaves as $4\kappa^2/3p^2$ for small $p$. When $\Pi^{(TAG)}_T$ and $\Pi^{P(TAG)}_T$ are combined (remember $\Pi^{(TAG)}_T = \frac{1}{2} \Pi^{(TAG)}_u(0, \kappa)$), the $\kappa^2/p^2$ singularities cancel and the integrand becomes regular as $p \to 0$. Indeed we find the sum of $\Pi^{(TAG)}_T$ and $\Pi^{P(TAG)}_T$ coincides with $\Pi_T$ in Eq.(3.14).

### 4 Summary and Discussion

The calculation of the thermal $\beta$ function $\beta_T$ was performed in four different gauges, that is, in BFM with an arbitrary gauge parameter, in FG, in CG, and in TAG. When the pinch contributions were taken care of, the same result $\beta_T = g^3 N \frac{T}{32 \kappa}$ was obtained at one-loop order in all four cases.

However, this is not the end of the story. Elmfors and Kobes pointed out [11] that the leading contribution to $\beta_T$, which gives a term $T/\kappa$, does not come from the hard part of the loop integral, responsible for a $T^2/\kappa^2$ term, but from soft loop integral. Hence they emphasized that it is not consistent to stop the calculation at one-loop order for soft internal momenta and that the resummed propagator and vertices [27] must be used to get the complete leading contribution. The need for resummation is urged also by the following observation: The fact that we have obtained the same $\beta_T$ at one-loop level in four different gauges implies that the effective gluon self-energy $\hat{\Pi}^{\mu\nu}$ in Eq.(3.20), constructed in BFM or in FG with recourse to PT, is gauge-fixing independent and universal. Provided that we use $\hat{\Pi}^{\mu\nu}$ for calculation of the gluon damping rate $\gamma$ at zero momentum, we would obtain $\gamma = -11 Ng^2 T/(24\pi)$ [28], a negative damping rate, which is not acceptable today [27].
Since the corrections to the bare propagator and vertices, which come from the hard thermal loops, are gauge-independent and satisfy simple Ward identities \[27\], it is well-expected that we will obtain the gauge-independent thermal $\beta$ function even when we use the resummed propagator and vertices in the framework of PT. Study along this direction is under way.

I would like to thank Professor A. Sirlin for the hospitality extended to me at New York University where this work was completed and for helpful discussions. I am also grateful to Professor D. Zwansiger, M. Schaden, J. Papavassiliou, K. Philippides and M. Passera for critical comments and discussions. This work is supported by Yokohama National University Foundation.
A Pinch contributions to gluon self-energy

In this Appendix we give the one-loop pinch contributions to the gluon self-energy from the vertex diagrams of the first kind ($V_1$), the vertex diagrams of the second kind ($V_2$), and box diagrams ($Box$), separately, calculated in four different gauges: (i) The background field method with an arbitrary $\xi_Q$; (ii) The Feynman gauge; (iii) The Coulomb gauge; (iv) The temporal axial gauge. The results in the cases of the background field method [13] and the Feynman gauge [17] are already known, but they are listed again for completeness. The expressions are in the imaginary time formalism and thus

$$\int dp = \int \frac{d^3p}{(2\pi)^3} T \sum_n$$

(A.1)

where the summation goes over $p_0 = 2\pi i n T$. They are transformed into the ones in the Minkowski space by the replacement $\int dp \Rightarrow -i \int d^4p/(2\pi)^4$.

A.1 The background field method with an arbitrary $\xi_Q$

$$\Pi^{\mu\nu(V_1)}_{P(BFM)} = Ng^2(1 - \xi_Q)k^2 d^{\mu\nu} \int dp \frac{1}{p^4} \quad (A.2)$$

$$\Pi^{\mu\nu(V_2)}_{P(BFM)} = Ng^2(1 - \xi_Q)k^2 d^{\mu\nu} \int dp \left[ -\frac{1}{p^2 q^2} - \frac{4k p^\gamma}{p^4 q^2} \right]
+ \frac{N}{2} g^2(1 - \xi_Q)^2 k^4 d^{\alpha\beta} d^{\mu\nu} \int dp \frac{-2p_\alpha p_\beta}{p^4 q^4} \quad (A.3)$$

$$\Pi^{\mu\nu(Box)}_{P(BFM)} = Ng^2(1 - \xi_Q)k^4 d^{\mu\nu} \int dp \frac{1}{p^4 q^2} \quad (A.4)$$

$$+ \frac{N}{2} g^2(1 - \xi_Q)^2 k^4 d^{\alpha\beta} d^{\mu\nu} \int dp \frac{p_\alpha p_\beta}{p^4 q^4}$$

A.2 The Feynman gauge

There are no contributions from the box and the vertex diagrams of the first kind. Thus we have $\Pi^{\mu\nu(V_1)}_{P(FG)} = \Pi^{\mu\nu(Box)}_{P(FG)} = 0$. The only contribution to the pinch part
comes from the vertex diagrams of the second:

\[
\Pi_{P(FG)}^{\mu\nu(V_2)} = 2Ng^2k^2d^{\mu\nu} \int dp \frac{-1}{p^2q^2}. \tag{A.5}
\]

### A.3 The Coulomb gauge

Only the \(\xi_C\)-independent parts of the pinch contributions are listed.

\[
\Pi_{P(CG)}^{\mu\nu(V_1)} = Ng^2k^2d^{\mu\nu} \int dp \frac{-4\vec{k} \cdot \vec{p}}{p^2q^2q^2} \tag{A.6}
\]

\[
\Pi_{P(CG)}^{\mu\nu(V_2)} = Ng^2k^2d^{\mu\nu} \int dp \frac{-4\vec{k} \cdot \vec{p}}{p^2q^2q^2} \nonumber + Ng^2k^2d^{\mu\nu} \int dp \frac{1}{p^2q^2q^2} \left\{ p_\alpha p_\beta (\vec{k}^2 - 2q^2) + n_\alpha n_\beta p_0 q_0 (k^2 + 2pq) \right. \nonumber \\
+ \left. (p_\alpha n_\beta + n_\alpha p_\beta) \frac{1}{2} [p_0 p^2 - q_0 q^2 + 2(p_0 - q_0) (p_0 q_0 - 2\vec{k} \cdot \vec{q})] \right\} \nonumber \\
\nonumber + N \frac{g^2}{2} \left[ d^{\mu\nu} \int dp \left\{ p_\alpha k^\nu \left( \frac{1}{q^2q^2} - \frac{1}{p^2q^2} \right) + \frac{1}{p^2q^2} \vec{k} \cdot \vec{q} \right\} \right. \nonumber \\
\nonumber + n_\alpha k^\nu \left[ - q_0 \frac{p_0}{q^2q^2} - \frac{p_0}{q^2q^2} + \left( \frac{q_0}{p^2} + \frac{p_0}{p^2} \right) \vec{k} \cdot \vec{q} \right] \right\} + (\mu \leftrightarrow \nu) \tag{A.7}
\]

\[
\Pi_{P(CG)}^{\mu\nu(Box)} = Ng^2k^2d^{\mu\nu} \int dp \frac{1}{p^2q^2q^2} \nonumber + \frac{N}{2} g^2 \left[ d^{\mu\nu} \int dp \left\{ p_\alpha p_\beta + (p_\alpha n_\beta + n_\alpha p_\beta) (q_0 - p_0) \right. \right. \nonumber \\
\nonumber \left. \left. - 2n_\alpha n_\beta p_0 q_0 \right\} \tag{A.8}
\]

### A.4 The temporal axial gauge

Only the \(\xi_A\)-independent parts of the pinch contributions are listed.

\[
\Pi_{P(TAG)}^{\mu\nu(V_1)} = Ng^2k^2d^{\mu\nu} \int dp \frac{-1}{p^2p_0^2} \tag{A.9}
\]

\[
\Pi_{P(TAG)}^{\mu\nu(V_2)} = Ng^2k^2d^{\mu\nu} \int dp \frac{-1}{p^2q_0^2} \left\{ \frac{2p^2}{p_0^2} - \frac{4\vec{k} \cdot \vec{p}}{p_0^2} \right\} \nonumber \\
\nonumber + Ng^2k^2d^{\mu\nu} \int dp \frac{1}{p^2q_0^2q_0^2} \left\{ p_\alpha p_\beta (\vec{k}^2 - 2q_0^2) + n_\alpha n_\beta p_0 q_0 (k^2 + 2pq) \right. \nonumber \\
\nonumber \left. - n_\alpha n_\beta p_0 q_0 \right\} \tag{A.10}
\]
\begin{align*}
+(p_\alpha n_\beta + n_\alpha p_\beta)[\frac{1}{2}(p_0p^2 - q_0q^2) - p_0(q^2 + 2\vec{p} \cdot \vec{q}) + q_0(p^2 + 2\vec{p} \cdot \vec{q})]\Biggr)\Biggr) \Biggr] 
(A.10)
\end{align*}

\[\Pi_{\mu\nu(\text{Box})}^{\rho(\text{TAG})} = Ng^2k^4d^4p \int \frac{1}{p^2q^2p_0^2} \]
\[+ \frac{N}{2} g^2k^4d^4p \int \frac{p_\alpha p_\beta + (p_\alpha n_\beta + n_\alpha p_\beta)(q_0 - p_0) - 2n_\alpha n_\beta p_0q_0}{p^2q^2p_0^2} \] 
(A.11)

**B Thermal one-loop integrals**

We list the thermal one-loop integrals in the static limit $k_0 = 0$ which are used in this paper. We only give the matter part. Due to the constraint $k + p + q = 0$ there holds a relation

\[\int dp f(p, q) = \int dp f(q, p). \] (B.1)

It is understood that in the r.h.s. of the expressions below, $p \equiv |\vec{p}|$, $\kappa \equiv |\vec{k}|$ and $n(p) = 1/[\exp(p/T) - 1]$.

\[\int dp \frac{p^2}{p^2q^2} = \frac{1}{4\pi^2}\int_0^\infty dp \frac{p^2}{2p} n(p) \ln\left|\frac{2p + \kappa}{2p - \kappa}\right| \] (B.2)

\[\frac{1}{k^2} \int dp \frac{\vec{k} \cdot \vec{p}}{p^2q^2} = \frac{1}{8\pi^2} \int_0^\infty dp n(p) \left\{2 + \frac{\kappa}{2p} \ln\left|\frac{2p + \kappa}{2p - \kappa}\right|\right\} \] (B.3)

\[\vec{k}^2 \int dp \frac{1}{p^2q^2} = \frac{\kappa}{4\pi^2}\int_0^\infty dp n(p) \ln\left|\frac{2p + \kappa}{2p - \kappa}\right| \] (B.4)

\[\vec{k}^2 \int dp \frac{\vec{k} \cdot \vec{p}}{p^4q^2} = \frac{\kappa}{8\pi^2}\int_0^\infty dp n(p) \left\{-\frac{4p\kappa}{(2p + \kappa)(2p - \kappa)} + \ln\left|\frac{2p + \kappa}{2p - \kappa}\right|\right\} \] (B.5)

\[\int dp \frac{\vec{k}^2\vec{p}^2 - (\vec{k} \cdot \vec{p})^2}{p^4q^2} = -\frac{1}{2}\vec{k}^2 \int dp \frac{1}{p^2q^2} \] (B.6)

\[\vec{k}^2 \int dp \frac{\vec{k}^2\vec{p}^2 - (\vec{k} \cdot \vec{p})^2}{p^4q^2} = \frac{\kappa}{4\pi^2}\int_0^\infty dp n(p) \left\{-\frac{2\kappa^2}{(2p + \kappa)(2p - \kappa)} + \frac{\kappa}{2p} \ln\left|\frac{2p + \kappa}{2p - \kappa}\right|\right\} \] (B.7)
\[ \int dp \frac{1}{p^2} = -\frac{1}{2\pi^2} \int_0^{\infty} dp \, p \, n(p) = -\frac{1}{12} T^2 \]  
(B.8)

\[ \int dp \frac{1}{p^2} = 0 \quad \text{(for matter part)} \]  
(B.9)

\[ \int dp \frac{p_0^2}{p^2 q^2} = -\frac{1}{4\pi^2 \kappa} \int_0^{\infty} dp \, p^2 \, n(p) \, \ln \left| \frac{p + \kappa}{p - \kappa} \right| \]  
(B.10)

\[ \int dp \frac{1}{p^2 q^2} \left[ |\vec{p} - \vec{q}|^2 (1 + c^2) + 8(\vec{p}^2 + \vec{q}^2)(1 - c^2) \right] \]
\[ = \frac{1}{2\pi^2} \int_0^{\infty} dp \, p \, n(p) \left\{ 5 + \frac{5 \kappa^2}{2p^2} + \frac{p^2 - \kappa^2}{4p^5 \kappa} \ln \left| \frac{p + \kappa}{p - \kappa} \right| \right. \]
\[ + \frac{32 p^6 + 40 p^4 \kappa^2 - 8 p^2 \kappa^4 - \kappa^6}{8p^5 \kappa} \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \} \]  
(B.11)

\[ \vec{k}^2 \int dp \frac{1}{p^2 q^2} = -\frac{\kappa}{4\pi^2} \int_0^{\infty} dp \, n(p) \ln \left| \frac{p + \kappa}{p - \kappa} \right| \]  
(B.12)

\[ \vec{k}^2 \int dp \frac{\vec{k} \cdot \vec{p}}{p^2 q^2 \vec{p}^2} = \frac{\kappa}{4\pi^2} \int_0^{\infty} dp \, n(p) \left\{ \frac{\kappa}{p} + \frac{\kappa^2 - p^2}{2p^2} \ln \left| \frac{p + \kappa}{p - \kappa} \right| - \frac{\kappa^2}{2p^2} \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \right\} \]  
(B.13)

\[ \vec{k}^2 \int dp \left[ 1 - \frac{(\vec{k} \cdot \vec{p})^2}{\vec{k}^2 \vec{p}^2} \right] \frac{1}{p^2 q^2} = \frac{\kappa}{4\pi^2} \int_0^{\infty} dp \, n(p) \left\{ -\frac{p}{2\kappa} + \frac{\kappa}{2p} \right. \]
\[ - \left[ 1 - \frac{(\kappa^2 + p^2)^2}{4\kappa^2 p^2} \right] \ln \left| \frac{p + \kappa}{p - \kappa} \right| + \left( 1 - \frac{\kappa^2}{4p^2} \right) \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \} \]  
(B.14)

\[ \vec{k}^4 \int dp \left[ 1 - \frac{(\vec{k} \cdot \vec{p})^2}{\vec{k}^2 \vec{p}^2} \right] \frac{1}{p^2 q^2 \vec{q}^2} = \frac{\kappa}{4\pi^2} \int_0^{\infty} dp \, n(p) \left\{ -\frac{\kappa}{p} \right. \]
\[ - \left[ 1 - \frac{(\kappa^2 + p^2)^2}{4\kappa^2 p^2} \right] \frac{2\kappa^2}{p^2} \ln \left| \frac{p + \kappa}{p - \kappa} \right| + \left( 1 - \frac{\kappa^2}{4p^2} \right) \frac{\kappa^2}{p^2} \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \} \]  
(B.15)
\[ \hat{k}^2 \int \frac{dp \hat{k}^2 + 4\hat{k} \cdot \hat{p}}{p^2 q^2 p_0^2} = \frac{1}{4\pi^2} \int_0^\infty dp \ p \ n(p) \left( -\frac{\kappa^3}{p^3} \right) \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \quad (B.16) \]

\[ \hat{k}^2 \int \frac{dp}{q^2 p_0^2} = \frac{1}{4\pi^2} \int_0^\infty dp \ p \ n(p) \left( -\frac{2\kappa^2}{p^2} \right) \quad (B.17) \]

\[ \hat{k}^2 \int \frac{dp}{p^2 p_0^2} = \frac{1}{4\pi^2} \int_0^\infty dp \ p \ n(p) \left( -\frac{2\kappa^2}{p^2} \right) \quad (B.18) \]

\[ \hat{k}^4 \int \frac{dp}{p^2 q^2 q_0^2} \left[ \frac{\hat{p}^2 - \left( \frac{\hat{k} \cdot \hat{p}}{k^2} \right)^2}{k^2} \right] = \frac{1}{4\pi^2} \int_0^\infty dp \ p \ n(p) \left\{ \frac{\kappa^4}{p^4} + \frac{\kappa^3 \left( 4p^2 - \kappa^2 \right)}{4p^5} \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \right\} \quad (B.19) \]

\[ \hat{k}^2 \int \frac{dp}{p^2 q^2 q_0^2} \left[ \frac{\hat{p}^2 - \left( \frac{\hat{k} \cdot \hat{p}}{k^2} \right)^2}{k^2} \right] = \frac{1}{4\pi^2} \int_0^\infty dp \ p \ n(p) \left\{ \frac{\kappa^2}{p^2} + \frac{\kappa \left( 4p^2 - \kappa^2 \right)}{4p^3} \ln \left| \frac{2p + \kappa}{2p - \kappa} \right| \right\} \quad (B.20) \]

For the \( \kappa \ll T \) expansion we use the following formulas [25]:

\[ \frac{1}{2} \ln \left| \frac{1 + x}{1 - x} \right| = \sum_{r=1}^{\infty} \frac{1}{2r - 1} \left( \frac{x}{1 - x} \right)^{2r-1} \quad (x < 1) \quad (B.21) \]

\[ = \sum_{r=1}^{\infty} \frac{1}{2r - 1} \left( \frac{x}{1 - x} \right)^{1-2r} \quad (x > 1) \quad (B.22) \]

\[ \int_0^1 dx \frac{x^s}{e^{yx} - 1} = \frac{1}{sy} + \cdots \quad (B.23) \]

\[ \int_1^\infty dx \frac{1}{x^s (e^{yx} - 1)} = \frac{1}{sy} + \cdots \]

\[ = \frac{1}{y} + \frac{1}{2} \ln y + \cdots, \quad \text{if} \ s = 1 \quad (B.24) \]
