ABSTRACT. Let $\mu$ be a positive finite measure on the unit circle and $D(\mu)$ the associated Dirichlet space. The generalized Brown-Shields conjecture asserts that an outer function $f \in D(\mu)$ is cyclic if and only if $c_\mu(Z(f)) = 0$, where $c_\mu$ is the capacity associated with $D(\mu)$ and $Z(f)$ is the zero set of $f$. In this paper we prove that this conjecture is true for measures with countable support. We also give in this case a complete and explicit characterization of invariant subspaces.

1. INTRODUCTION

The Dirichlet space $D(\mu)$, associated with $\mu$, consists of holomorphic functions on the unit disc whose derivatives are square integrable when weighted against the Poisson integral of $\mu$. In this paper we study cyclic vectors and invariant subspaces of the shift operator on $D(\mu)$. The corresponding problem for the Hardy space $H^2$ was solved by Beurling in [3]: the cyclic vectors are precisely the outer functions and the invariant subspaces are generated by inner functions. Brown–Shields in [5] studied cyclicity in the classical Dirichlet space $D$. They proved that the set of zeros of cyclic functions in the Dirichlet space has zero logarithmic capacity and this led them to ask whether any outer function with this property is cyclic, see also [7, 8, 13, 18] on the study of cyclic vectors. A series of results was obtained by Richter and Richter–Sundberg in [14, 15, 16, 17, 18] for Dirichlet spaces $D(\mu)$ and especially for the description of their invariant subspaces. More recently, Guillot in [11] obtained a precise characterization of cyclic vectors for Dirichlet spaces associated with finitely atomic measures. We refer the reader to [9] on these problems. In this work, we focus our attention in the study of the cyclic vectors and the invariant subspaces for the shift operator acting on the Dirichlet space $D(\mu)$ associated with the measures with countable support.

We now introduce the necessary notation. Let $H^2$ be the classical Hardy space of the open unit disc $\mathbb{D}$. If $\mu$ is a positive Borel measure on $\mathbb{T}$, the Dirichlet space $D(\mu)$ is the set of all functions $f \in H^2$ such that

$$D_\mu(f) = \frac{1}{\pi} \int_{\mathbb{D}} |f'(z)|^2 P_\mu(z) dA(z) < \infty,$$

where $D_\mu(f)$ is the Dirichlet integral of $f$ weighted by $\mu$. The capacity $c_\mu$ is defined as

$$c_\mu(Z(f)) = \lim_{r \to 0} \frac{1}{\pi} \int_{Z(f)} |f'(z)|^2 P_\mu(z) dA(z).$$
where \( dA(re^{it}) = (1/\pi)rdrdt \) denotes the normalized area measure on \( \mathbb{D} \) and \( P_\mu \) is the Poisson integral of \( \mu \):

\[
P_\mu(z) = \int_{\mathbb{D}} \frac{1 - |z|^2}{|1 - \zeta z|^2} d\mu(\zeta).
\]

The space \( \mathcal{D}(\mu) \) is endowed with the norm

\[
\|f\|_\mu^2 := \|f\|_{H^2}^2 + \mathcal{D}_\mu(f).
\]

The classical Dirichlet space \( \mathcal{D} \) is precisely \( \mathcal{D}(m) \) where \( m \) denotes the normalized Lebesgue measure.

Given \( f \in \mathcal{D}(\mu) \), we denote by \([f]_{\mathcal{D}(\mu)}\) the smallest invariant subspace of \( \mathcal{D}(\mu) \) containing \( f \); namely,

\[
[f]_{\mathcal{D}(\mu)} := \{pf : p \text{ is a polynomial}\}.
\]

We say that \( f \) is cyclic for \( \mathcal{D}(\mu) \) if \([f]_{\mathcal{D}(\mu)} = \mathcal{D}(\mu) \). Denote by \( S \) the shift operator on \( \mathcal{D}(\mu) \), that is the multiplication by \( z \) on \( \mathcal{D}(\mu) \). A closed subspace \( \mathcal{M} \) of \( \mathcal{D}(\mu) \) is called invariant if \( SM \subset M \). The lattice of all closed invariant subspaces of the shift operator will be denoted by \( \text{Lat}(S, \mathcal{D}(\mu)) \).

In this paper we are interested in a characterization of the cyclic functions of \( \mathcal{D}(\mu) \) and in a description of \( \text{Lat}(S, \mathcal{D}(\mu)) \). If \( d\mu(e^{it}) = 0 \) then \( \mathcal{D}(0) = H^2 \), and, in this case, Beurling’s theorem asserts that all closed invariant subspaces are given by \( \Theta H^2 \), where \( \Theta \) is an inner function. As a consequence, a function \( f \in H^2 \) is cyclic for \( H^2 \) if and only if \( f \) is outer. In order to extend Beurling’s theorem to the classical Dirichlet space, Richter in [15] was led to introduce Dirichlet type spaces. First, he proved that every cyclic, analytic 2-isometry is unitarily equivalent to the shift operator on some \( \mathcal{D}(\mu) \). Recall that a bounded operator on a Hilbert space is called 2-isometry if

\[
T^*T - 2T^*T - I = 0
\]

and it is called analytic if \( \cap_{n \geq 0} T^n_{\mathcal{H}} = \{0\} \). This result allowed him to prove that every invariant subspace for \( \mathcal{D} \) is of the form \( \phi \mathcal{D}(|\phi|^2dm) \), where \( \phi \) is an extremal function for \( \mathcal{D} \), that is

\[
\|\phi\|_\mu = 1 \quad \text{and} \quad \langle \phi, z^n \phi \rangle_{\mathcal{D}(\mu)} = 0, \quad n \geq 1.
\]

This characterization does not allow to describe the cyclic functions for \( \mathcal{D} \). Brown and Shields showed in [5] that if \( f \) is cyclic for \( \mathcal{D} \) then \( f \) is outer and the zero set of its radial limit

\[
\mathcal{Z}_T(f) = \{\zeta \in \mathbb{T} : \lim_{r \to 1^-} f(r\zeta) = 0\}
\]

is of logarithmic capacity zero. Brown and Shields further conjectured that the converse is also true. This problem remains open, some partial results of this conjecture can be found in [9, 13, 18].
Richter and Sundberg in [18] extended the characterization of invariant subspaces to all Dirichlet spaces. Indeed, they proved that
\[ \text{Lat}(S, \mathcal{D}(\mu)) = \{ \phi \mathcal{D}(|\phi|^2 d\mu) : \phi \text{ is an extremal function for } \mathcal{D}(\mu) \}. \]
As before, the description of cyclic functions remains an open problem. To state a general Brown-Shields conjecture we will introduce a notion of capacity associated with these spaces.

The harmonic Dirichlet space, \( \mathcal{D}^h(\mu) \), associated with \( \mu \) is given by
\[ \mathcal{D}^h(\mu) := \{ f \in L^2(T) : \|f\|_2^2 + \mathcal{D}_\mu(f) < \infty \}, \]
where \( \mathcal{D}_\mu(f) = \int_T |\nabla P[f]|^2 P_\mu dA \). Note that \( \mathcal{D}^h(\mu) \) is a Dirichlet space in the sense of Beurling–Deny, and following [4], the \( c_\mu \)-capacity of an open subset \( U \subset \mathbb{T} \) is defined by
\[ c_\mu(U) := \inf \{ \|u\|^2_2 : u \in \mathcal{D}^h(\mu), \ u \geq 0 \text{ and } u \geq 1 \text{ a.e. on } U \}. \]
As usual we define the \( c_\mu \)-capacity of any subset \( F \subset \mathbb{T} \) by
\[ c_\mu(F) = \inf \{ c_\mu(U) : U \text{ open, } F \subset U \}. \]
The capacity \( c_\mu \) is the Choquet capacity [6, 11] and so for every borelian subset \( E \) of \( \mathbb{T} \) we have
\[ c_\mu(E) = \sup \{ c_\mu(K) : K \text{ compact, } K \subset E \}. \]
In the case \( \mu = m \), it is well known that \( c_m \) is comparable to the logarithmic capacity. For more details see [1, Theorem 2.5.5].

We say that a property holds \( c_\mu \)-quasi-everywhere (\( c_\mu \)-q.e.) if it holds everywhere outside a set of \( c_\mu \)-capacity 0. So, \( c_\mu \)-q.e. implies a.e. Note that for every function \( f \in \mathcal{D}(\mu) \), the radial limits of \( f \) exist q.e., see [11]. Recall also that \( c_\mu \) satisfies a weak-type inequality, namely:
\[ c_\mu(\{ \zeta \in \mathbb{T} : |f(\zeta)| \geq t \text{ } c_\mu \text{-q.e.} \}) \leq \frac{\|f\|^2_\mu}{t^2}, \quad f \in \mathcal{D}^h(\mu). \]
As consequence, the invariant subspace \( \mathcal{M}_\mu(E) \) defined by
\[ \mathcal{M}_\mu(E) := \{ g \in \mathcal{D}(\mu) : g|E = 0 \text{ } c_\mu \text{-q.e.} \}, \]
is closed in \( \mathcal{D}(\mu) \). Using these facts it is easy to verify that if \( f \) is cyclic in \( \mathcal{D}(\mu) \) then \( f \) is outer and \( c_\mu(\Xi(f)) = 0 \), where the generalized Brown-Shields conjecture claims that the converse is also true.

For \( f \in \mathcal{D}(\mu) \), and \( \mathcal{M} \in \text{Lat}(S, \mathcal{D}(\mu)) \), denote by \( \Xi(f) \) the zeros set of \( f \) on the disc and set
\[ \Xi(f) := \{ \zeta \in \mathbb{D} : \liminf_{z \to \zeta} |f(z)| = 0 \}. \]
and
\[ \Xi(\mathcal{M}) := \bigcap_{f \in \mathcal{M}} \Xi(f). \]
Note that both sets are closed. If \( f \) is an inner function, then \( \mathcal{Z}(f) \) is the spectrum of \( f \), and then \( f \) admits analytic continuation through \( T \setminus \mathcal{Z}(f) \).

In this paper we will prove the following two results:

**Theorem 1.** Let \( \mu \) be a positive finite measure on \( T \). Let \( f \in \mathcal{D}(\mu) \) be such that \( \text{supp } \mu \cap \mathcal{Z}(f) \) is countable. The following assertions are equivalent.

1. \( f \) is cyclic for \( \mathcal{D}(\mu) \).
2. \( f \) is an outer function and \( c_\mu(\mathcal{Z}_T(f)) = 0 \).

This theorem asserts, in particular, that the generalized Brown–Shields conjecture is true if the support of \( \mu \) is countable. We also obtain, in this case, an explicit characterization of invariant subspaces of \( \mathcal{D}(\mu) \).

Let \( \mathcal{M} \in \text{Lat}(S, \mathcal{D}(\mu)) \), we denote by \( \Theta_\mathcal{M} \) the greatest common inner divisor of the inner parts of the non-zero functions of \( \mathcal{M} \) and

\[
\mathcal{Z}_T(\mathcal{M}) = \bigcap_{f \in \mathcal{M}} \mathcal{Z}_T(f).
\]

We have the following characterization which completes the Richter–Sundberg result [18] (see Theorem 2.6) in the case when \( \text{supp } \mu \) is countable.

**Theorem 2.** Let \( \mu \) be a positive finite measure on \( T \) such that \( \text{supp } \mu \) is countable. Let \( \mathcal{M} \in \text{Lat}(S, \mathcal{D}(\mu)) \) and let \( \Theta_\mathcal{M} \) be the greatest common inner divisor of \( \mathcal{M} \). Then,

\[
\mathcal{M} = \Theta_\mathcal{M} H^2 \cap \mathcal{M}_\mu(E),
\]

where \( E = \{ \lambda \in \text{supp } \mu : c_\mu(\{ \lambda \}) > 0 \text{ and } \lambda \in \mathcal{Z}_T(\mathcal{M}) \} \).

Note that by [10, Corollary 5.2]

\[
c_\mu(\{ \lambda \}) > 0 \iff \int_0^1 \frac{dr}{(1-r)P_\mu(r\lambda) + (1-r)^2} < +\infty.
\]

The plan of the paper is the following. The next section gives a background on Dirichlet spaces. In Section 3, we give a description of invariant subspaces generated by polynomials. In Sections 4 we collect some results on closed ideals of \( \mathcal{D}(\mu) \cap H^\infty \). Sections 5 and 6 are devoted to the proof of Theorems 1 and 2.

## 2. Background on the Dirichlet Type Spaces

In this section we recall some results from the Richter–Sundberg papers [16, 17, 18] about Dirichlet type spaces which will be used in the proofs of our Theorems, see also [9].

Every function \( f \in H^2 \) has non-tangential limits almost everywhere on the unit circle \( T = \partial \mathbb{D} \). We denote by \( f(\zeta) \) the non-tangential limit of \( f \) at \( \zeta \in T \) if it exists.
Let \( \mu \) be a positive finite measure on the unit circle, the associated Dirichlet space \( \mathcal{D}(\mu) \) is the set of all analytic functions \( f \in H^2 \), such that
\[
\mathcal{D}_\mu(f) := \int_\mathbb{T} \mathcal{D}_\xi(f) d\mu(\xi) < \infty,
\]
where \( \mathcal{D}_\xi(f) \) is the local Dirichlet integral of \( f \) at \( \xi \in \mathbb{T} \) given by
\[
\mathcal{D}_\xi(f) := \int_\mathbb{T} \frac{|f(e^{it}) - f(\xi)|^2 dt}{|e^{it} - \xi|^2}.
\]
Here \( f(\lambda) (\lambda = e^{it} or \zeta) \) is the radial limit of \( f \) at \( \lambda \), that is \( f(\lambda) = \lim_{r \to 1^-} f(r\lambda) \).

Recall that a function \( I \) is inner if it is a bounded holomorphic function on \( \mathbb{D} \) such that \( |I| = 1 \) a.e. on \( \mathbb{T} \). The function \( O \) is called outer if it is of the form
\[
O(z) = \exp \frac{1}{2\pi} \int_\mathbb{T} \frac{\zeta + z}{\zeta - z} \log \varphi(\zeta)|d\zeta|, \quad z \in \mathbb{D}.
\]
where \( \varphi \) is a positive function such that \( \log \varphi \in L^1(\mathbb{T}) \). Note that \( |f| = \varphi \) a.e. on \( \mathbb{T} \).

**Theorem 2.1.** Let \( f \in H^2 \) and \( f = BS_\nu f_o \) with \( B \) a Blaschke product, \( \nu \) a singular measure associated with \( S_\nu \) a singular inner factor of \( f \), \( f_o \) an outer function and let \( \zeta \in \mathbb{T} \) such that \( f_o(\zeta) \) exists. Then
\[
\mathcal{D}_\zeta(f) = \sum_{\gamma \in \mathcal{Z}(B)} P_{\delta_\gamma}(\zeta)|f_o(\zeta)|^2 + 2 \int_\mathbb{T} \frac{d\nu(\lambda)}{|\lambda - \zeta|^2} |f_o(\zeta)|^2
\]
\[
+ \int_\mathbb{T} \frac{|f(\lambda)|^2 - |f(\zeta)|^2 - 2|f(\zeta)|^2 \log |f(\lambda)/f(\zeta)| |d\lambda|}{|\lambda - \zeta|^2} \quad \text{(1)}
\]
where \( \delta_\gamma \) is the Dirac measure on \( \gamma \).

**Proof.** See [16, Theorem 3.1]. \( \square \)

**Theorem 2.2.** Let \( f, g \in \mathcal{D}(\mu) \). If \( |f(z)| \leq |g(z)| \) on \( \mathbb{D} \), then \( [f]_{\mathcal{D}(\mu)} \subset [g]_{\mathcal{D}(\mu)} \).

**Proof.** See [16, Theorem 4.1]. \( \square \)

If \( f \) and \( g \) are outer functions, then we define the outer function function \( f \wedge g \) by \( \min\{ |f(e^{it})|, |g(e^{it})| \} \) and \( f \vee g \) by \( \max\{ |f(e^{it})|, |g(e^{it})| \} \).

**Theorem 2.3.** Let \( f, g \) be outer functions in \( \mathcal{D}(\mu) \), then \( f \wedge g \) and \( f \vee g \) belongs to \( \mathcal{D}(\mu) \) and \( \|f \wedge g\|_\mu^2 \leq \|f\|_\mu^2 + \|g\|_\mu^2 \) and \( \|f \vee g\|_\mu^2 \leq \|f\|_\mu^2 + \|g\|_\mu^2 \).

**Proof.** see [17, Lemma 2.2] \( \square \)

**Theorem 2.4.** Let \( f, g \in \mathcal{D}(\mu) \) be outer functions and let \( h \) be the outer function given by \( |h| := |f| \wedge |g| \) a.e on \( \mathbb{T} \). Then \( [h]_{\mathcal{D}(\mu)} = [f]_{\mathcal{D}(\mu)} \cap [g]_{\mathcal{D}(\mu)} \). If further \( fg \in \mathcal{D}(\mu) \), then \( [fg]_{\mathcal{D}(\mu)} = [f]_{\mathcal{D}(\mu)} \cap [g]_{\mathcal{D}(\mu)} \).
Proof. See [17, Theorem 4.5].

\[\square\]

**Theorem 2.5.** Let \( \mathcal{M} \in \text{Lat}(S, \mathcal{D}(\mu)) \). Then there exists a multiplier \( \phi \) of \( \mathcal{D}(\mu) \) such that \( \mathcal{M} = \phi \mathcal{D}(\mu) \).

*Proof.* See [17, Theorem 3.5] and [18, Theorem 3.2]. \(\square\)

**Theorem 2.6.** Let \( \mathcal{M} \in \text{Lat}(S, \mathcal{D}(\mu)) \), and let \( \Theta_M \) the greatest common inner divisor of \( \mathcal{M} \). Then, there is an outer \( f \in \mathcal{D}(\mu) \cap H^\infty \) such that \( \mathcal{M} = \Theta_M H^2 \cap [f] \mathcal{D}(\mu) \).

In fact \( f \) can be chosen so that \( f \) and \( \Theta_M f \) are multipliers of \( \mathcal{D}(\mu) \).

*Proof.* See [17, Theorem 5.3]. \(\square\)

### 3. Invariant subspaces generated by polynomials

In this section we characterize closed invariant subspaces generated by polynomials. Let \( \zeta \in \mathbb{T} \). We will say that \( \zeta \) is a bounded point evaluation of \( \mathcal{D}(\mu) \) if there exists a constant \( M > 0 \) such that for every polynomial \( p \)

\[ |p(\zeta)| \leq M \| p \|_\mu. \]

It means that the functional \( p \to p(\zeta) \) extends to a continuous functional on \( \mathcal{D}(\mu) \). Since the polynomials are dense in \( \mathcal{D}(\mu) \), this extension is unique and will be denoted by \( L_\zeta(f) = f(\zeta) \).

Let \( c^a_\mu(E) = \inf \{ \| f \|^2_\mu : f \in \mathcal{D}(\mu) \text{ and } |f| \geq 1 \text{ a.e. on a neighborhood of } E \} \).

Since

\[ \| f \|_\mu \geq \| f_o \|_\mu \geq \| f_o \wedge 1 \|_\mu, \]

where \( f_o \) is the outer part of \( f \), see for instance [9, Corollary 7.6.2], then

\[ c^a_\mu(E) = \inf \{ \| f \|^2_\mu : f \in \mathcal{D}(\mu) \text{ is an outer function, } |f| = 1 \text{ a.e. on a neighborhood of } E \}. \]

Note that \( c^a_\mu(E) \leq c^a_\mu(E) \). In fact \( c^a_\mu \) is comparable to \( c_\mu \) by the following Lemma (see [12, Theorem 38]).

*For the sake of completeness, we give the proof*

**Lemma 3.1.** We have \( c_\mu(E) \leq c^a_\mu(E) \leq 4c_\mu(E) \)

*Proof.* Let \( \varepsilon \geq 0 \) and let \( f \in \mathcal{D}_h(\mu) \) such that \( |f| \geq 1 \text{ a.e. on a neighborhood of } E \) and \( \| f \|^2_\mu \leq c_\mu(E) + \varepsilon \). Write \( f = f_1 + f_2 \) where \( f_1 \in \mathcal{D}(\mu), f_2(0) = 0, \| f \|^2_\mu = \| f_1 \|^2_\mu + \| f_2 \|^2_\mu \) and so for \( i = 1 \) or \( i = 2 \), we have \( |f_i| \geq 1/2 \text{ a.e. on a neighborhood of } E \).

Consider the outer function \( \varphi = f_1 \vee f_2 \text{ a.e. on } \mathbb{T} \). By Theorem 2.3, \( \varphi \in \mathcal{D}(\mu) \) and \( \| \varphi \|^2_\mu \leq \| f_1 \|^2_\mu + \| f_2 \|^2_\mu = \| f \|^2_\mu \). Since \( |\varphi| \geq 1/2 \text{ a.e. on a neighborhood of } E \), we get \( c^a_\mu(E) \leq 4\| \varphi \|^2_\mu \leq 4\| f \|^2_\mu \leq 4c_\mu(E) + \varepsilon. \) \(\square\)
Using this fact, we have the following lemma.

**Lemma 3.2.** Let $\zeta \in \mathbb{T}$. The following properties are equivalent:

1. $\zeta$ is a bounded point evaluation of $\mathcal{D}(\mu)$.
2. The polynomial $z - \zeta$ is not cyclic for $\mathcal{D}(\mu)$.
3. $c_\mu(\zeta) > 0$.

**Proof.** (1) $\implies$ (3): Suppose that $\zeta$ is a bounded point evaluation for $\mathcal{D}(\mu)$. We will prove that $c_\mu^0(\zeta) > 0$. Let $f \in \mathcal{D}(\mu)$ be an outer function such that $|f| = 1$ a.e. on an open arc $I$ centered at $\zeta$. Then, there is $\lambda \in \mathbb{T}$ such that

$$f(z) = \lambda \exp \frac{1}{2\pi} \int_{\mathbb{T}} \frac{\eta + z}{\eta - z} \log |f(\eta)| \, d\eta, \quad z \in \mathbb{D}.$$ 

Hence $f$ is analytic in a neighborhood of $\zeta$. Since $L_\zeta$ is bounded, we have $|L_\zeta(f)| = |f(\zeta)| = 1$. So $\|f\|_\mu \geq 1/\|L_\zeta\|$, and consequently, $c_\mu^0(\zeta) \geq 1/\|L_\zeta\|^2$. This proves that (1) implies (3).

(3) $\implies$ (2): Suppose that $c_\mu(\zeta) > 0$. Then $\mathcal{M}_\mu(\{\zeta\})$ is a proper closed invariant subspace of $\mathcal{D}(\mu)$ and $z - \zeta$ is not cyclic.

(2) $\implies$ (1): Suppose now that $z - \zeta$ is not cyclic for $\mathcal{D}(\mu)$. The space $\mathcal{D}(\mu)/[(z - \zeta)]_{\mathcal{D}(\mu)}$ is of dimension one. Let $\pi$ be the canonical surjection defined by

$$\pi : \mathcal{D}(\mu) \to \mathcal{D}(\mu)/[(z - \zeta)]_{\mathcal{D}(\mu)}, \quad f \to \pi(f) = f + [(z - \zeta)]_{\mathcal{D}(\mu)}$$

and let $\rho$ be the isomorphism from $\mathcal{D}(\mu)/[(z - \zeta)]_{\mathcal{D}(\mu)}$ to $\mathbb{C}$ satisfying $\rho(\pi(1)) = 1$. It is easy to verify that $L_\zeta = \rho \circ \pi$, which proves that $L_\zeta$ is continuous. 

**Lemma 3.3.** Let $\zeta \in \mathbb{T}$ and let $n$ be an integer $n \geq 1$. We have

1. If $c_\mu(\zeta) = 0$ then $[(z - \zeta)^n]_{\mathcal{D}(\mu)} = \mathcal{D}(\mu)$.
2. If $c_\mu(\zeta) > 0$ then $[(z - \zeta)^n]_{\mathcal{D}(\mu)} = \mathcal{M}_\mu(\zeta)$.

**Proof.** By Theorem 2.4, we have $[(z - \zeta)^n]_{\mathcal{D}(\mu)} = [(z - \zeta)]_{\mathcal{D}(\mu)}$. The two assertions come from Lemma 3.2.

To state the characterization of closed invariant subspaces generated by polynomials, we need some notations.

To any $\Lambda = \{(z_1, n_1), (z_2, n_2), \ldots, (z_k, n_k)\}$, where $z_j \in \mathbb{D}$ and $n_j \in \mathbb{N}^*$, we associate a polynomial $p_\Lambda = \prod_{j=1}^k (z - z_j)^{n_j}$. Let $E \subset \mathbb{T}$, we define

$$\mathcal{M}_\mu(\Lambda, E) = \{ f \in \mathcal{D}(\mu) : f \in p_\Lambda H^2 \text{ and } f|_E = 0 \}.$$ 

For a polynomial $p$, let $\Lambda_p = \{(z, n) \in \mathbb{D} \times \mathbb{N}^* : z \text{ is a zero of } p \text{ of order } n\}$. We have

**Theorem 3.4.** Let $p$ be a polynomial. Then

$$[p]_{\mathcal{D}(\mu)} = \mathcal{M}_\mu(\Lambda_p, E),$$
where \( E = \{\zeta \in T : p(\zeta) = 0 \text{ and } c_\mu(\zeta) > 0\} \).

Proof. The proof is based on classical arguments and on the Lemma 3.3.

\( \square \)

4. Closed Ideals of \( \mathcal{D}(\mu) \cap H^\infty \)

First, we will state the following lemmas which will be used in the sequel.

Lemma 4.1. Let \( f \in \mathcal{D}(\mu) \cap H^\infty \) and \( g \in H^\infty \) be outer functions such that \( \|f\|_\infty \leq 1 \) and \( \|g\|_\infty \leq 1 \). Let \( h \) be the outer function given by

\[
|h(\zeta)| = \begin{cases} |f(\zeta)|, & \text{a.e. on } V, \\ |g(\zeta)|, & \text{a.e. on } T \setminus V, \end{cases}
\]

where \( V \) is a closed neighborhood of \( \text{supp}(\mu) \). Then \( h \in \mathcal{D}(\mu) \) and

\[
\mathcal{D}_\mu(h) \leq \mathcal{D}_\mu(f) + \frac{\mu(T)}{\text{dist}(T \setminus V, \text{supp}(\mu))^2} \left( \|g\|_2^2 + 2\|f\|_2 \log 1/\|g\|_{L^2(T)} \right) .
\]  

(2)

Proof. Note that \( \|h\|_2^2 \leq \|f\|_2^2 + \|g\|_2^2 \), so \( h \in H^2 \). Since \( f \in \mathcal{D}(\mu) \), \( \mathcal{D}_\zeta(f) < \infty \) for \( \mu \)-almost every \( \zeta \in T \). By (1), for \( \zeta \in \text{supp} \mu \), let \( \delta = \text{dist}(T \setminus V, \text{supp}(\mu)) \), we have

\[
\mathcal{D}_\zeta(h) = \int_{\lambda \in V} + \int_{\lambda \in T \setminus V} \frac{|h(\lambda)|^2 - |h(\zeta)|^2 - 2|h(\zeta)|^2 \log |h(\lambda)/h(\zeta)|}{|\lambda - \zeta|^2} \frac{d\lambda}{2\pi} \\
\leq \mathcal{D}_\zeta(f) + \frac{1}{\delta^2} \int_{\lambda \in T \setminus V} \left(|g(\lambda)|^2 + 2|f(\zeta)|^2 \log \frac{1}{|g(\lambda)|} - |f(\zeta)|^2 \log \frac{e}{|f(\zeta)|^2} \right) \frac{|d\lambda|}{2\pi} \\
\leq \mathcal{D}_\zeta(f) + \frac{1}{\delta^2} \left( \|g\|_2^2 + 2|f(\zeta)|^2 \int_T \frac{\log \frac{1}{|g(\lambda)|}}{2\pi} \right).
\]

It’s clear that (2) follows from this inequality and thus \( h \in \mathcal{D}(\mu) \).

\( \square \)

Lemma 4.2. Let \( V = (e^{ia}, e^{ib}) \), and let \( f \in \mathcal{D}(\mu) \cap H^\infty \) be an outer function. Let \( f_V \) be the outer function defined by

\[
|f_V(\zeta)| = \begin{cases} \Re(\zeta - e^{ia})(e^{ib} - \zeta)|f(\zeta)|, & \text{a.e. on } V, \\ \Re(\zeta - e^{ia})(e^{ib} - \zeta), & \text{on } T \setminus V. \end{cases}
\]

Then \( f_V \in \mathcal{D}(\mu) \cap H^\infty \).

Proof. Set \( u(z) = (z - e^{ia})(e^{ib} - z) \), again by (1), for \( \zeta \in \text{supp} \mu \), we have

\[
\mathcal{D}_\zeta(f_V) = \int_{\lambda \in V} + \int_{\lambda \in T \setminus V} \frac{|u(\lambda)|^2 - |u(\zeta)|^2 - 2|u(\zeta)|^2 \log |u(\lambda)/u(\zeta)|}{|\lambda - \zeta|^2} \frac{d\lambda}{2\pi} \\
\leq \mathcal{D}_\zeta(f) + \mathcal{D}_\zeta(u).
\]

Clearly, \( f_V \in \mathcal{D}(\mu) \cap H^\infty \).

\( \square \)
Recall that $D(\mu) \cap H^\infty$ is a Banach algebra endowed with the pointwise multiplication and equipped with the norm

$$\|f\|_{\infty, \mu} = \|f\|_\infty + D(\mu)(f)^{1/2}.$$ 

**Theorem 4.3.** Let $J$ be a closed ideal of $D(\mu) \cap H^\infty$. Let 

$$\pi: D(\mu) \cap H^\infty \to D(\mu) \cap H^\infty / J,$$ 

be the canonical surjection. Then 

$$\sigma(\pi(u)) = \overline{\mathcal{Z}(J)}$$

where $u : z \to z$ is the identity map and $\sigma(\pi(u))$ is the spectrum of $\pi(u)$.

**Remark.** Note that $\sigma(\pi(u)) = \emptyset$ if and only if $J = D(\mu) \cap H^\infty$, see Lemma 5.1 for more general statement.

**Proof Theorem 4.3.** First, we prove that $\overline{\mathcal{Z}(J)} \subset \sigma(\pi(u))$. Let $\lambda \notin \sigma(\pi(u))$, then there exists $f \in D(\mu) \cap H^\infty$ and $g \in J$ such that $(\lambda - z)f(z) = 1 - g(z)$. Which gives obviously that $\lim_{z \to \lambda} g(z) = 1$ and $\lambda \notin \overline{\mathcal{Z}(J)}$.

Conversely, let $\lambda \notin \overline{\mathcal{Z}(J)}$. We suppose that $|\lambda| = 1$ since the case $|\lambda| \neq 1$ is obvious. Hence there exists $g \in J$ and $c > 0$ such that $|g(z)| \geq c$ on a neighborhood of $\lambda$, $V_\lambda = \{z \in \mathbb{D} : |z - \lambda| \leq \delta/2\}$.

Note that if $w \in C^2(\mathbb{T})$ and $\log |w| \in L^1(\mathbb{T})$ then the outer function $f_w$ defined by $|f_w| = w$, a.e. on $\mathbb{T}$, belongs to $C^2(\overline{\mathbb{D}}) \cap \text{Hol}(\mathbb{D}) \subset D(\mu)$. Now consider the smooth function $w \in C^2(\mathbb{T})$ such that $w \geq c > 0$ and 

$$w(z) = \begin{cases} 
    c & \text{if } |z - \lambda| \leq \delta/2, \\
    1 & \text{if } |z - \lambda| \geq \delta.
\end{cases}$$

Suppose that $\|g\|_\infty \leq 1$. Write $g = g_ig_o$ the inner–outer factorization of $g$. Consider the outer function 

$$|h| = |g_o| \wedge |f_w| = |g_o| \wedge |w| \quad \text{a.e. on } \mathbb{T}.$$ 

Note that $|h| = c$ near $\lambda$ and by Theorem 2.4, $0 \neq h \in D(\mu)$. Now consider the outer function 

$$\tilde{h}(e^{it}) = (|g_o| \vee |f_w|)(e^{it}) = \max\{|g_o(e^{it})|, w(e^{it})\}, \quad \text{a.e. on } \mathbb{T}.$$ 

Clearly, 

$$gf_w = g_i(g_o \wedge f_w) \times (g_o \vee f_w) = g_ih \times \tilde{h} \quad \text{on } \mathbb{D}$$

and $\tilde{h} \in D(\mu) \cap H^\infty$ is invertible. So $g_ih \in J$. Since $|g(z)| \geq c$ on $V_\lambda$, then $\lambda$ doesn’t belong to the spectrum of the inner function $g_i$. Therefore $g_i$ is analytic across an arc that contains $\lambda$, so $g_i(\lambda)$ is well-defined and $|g_i(\lambda)| = 1$. Let 

$$\psi = \frac{1}{(g_ih)(\lambda)} \frac{g_ih - g_ih(\lambda)}{u - \lambda}.$$
Since \((g,h)(\lambda) \neq 0\), the function \(\psi\) is well-defined. Note that the function \(|g_o||f_w| = |f_w|
 on \\{\zeta \in \mathbb{T} : |\zeta - \lambda| \leq \delta/2\} is \(C^\infty\) on \(V_\lambda\) and
\[
h(z) = \exp \int_{|\zeta - \lambda| \leq \delta/2} \frac{\zeta + z}{\zeta - z} \log c \frac{|d\zeta|}{2\pi} \times \exp \int_{|\zeta - \lambda| \geq \delta/2} \frac{\zeta + z}{\zeta - z} \log |h(\zeta)| \frac{|d\zeta|}{2\pi},
\]
the two functions are clearly \(C^\infty\) on \(V_\lambda\) and hence \(\psi\) is \(C^2\) on \(V_\lambda\). Thus \(\psi \in D(\mu) \cap H^\infty\). So \(\pi(\psi)(\lambda - \pi(u)) = \pi(1)\) and we get \(\lambda \not\in \sigma(\pi(u))\) which finishes the proof.

**Lemma 4.4.** Let \(J\) be a closed ideal of \(D(\mu) \cap H^\infty\) such that \(J\) contains an outer function, and \(\mathcal{Z}(J) = \{\zeta_0\} \subset \mathbb{T}\). Then \((z - \zeta_0) \in \mathcal{J}\).

**Proof.** We suppose that \(\zeta_0 = 1\). Consider again the canonical surjection
\[
\pi : D(\mu) \cap H^\infty \rightarrow D(\mu) \cap H^\infty/J,
\]
and let \(u : z \rightarrow z\) be the identity map. Given \(\lambda \in \mathbb{D}\) and \(f \in \mathcal{J}\), we define
\[
L_\lambda(f)(z) = \begin{cases} 
\frac{f(z) - f(\lambda)}{z - \lambda}, & z \in \mathbb{D} \setminus \{\lambda\}, \\
f'(\lambda), & z = \lambda.
\end{cases}
\]
Since \(L_\lambda f - L_0 f = \lambda L_\lambda L_0 f\), it is obvious that \(L_\lambda(f) \in D(\mu) \cap H^\infty\). So
\[
\pi(L_\lambda(f))((\lambda \pi(1) - \pi(u)) = f(\lambda)\pi(1), \quad \lambda \in \mathbb{D}.
\]
The operator \(T\) defined on \(D(\mu) \cap H^\infty/J\) by
\[
\pi(f) \rightarrow \pi(u)\pi(f),
\]
has the spectrum \(\sigma(T) = \{1\}\) and for \(n \geq 0\)
\[
\|T^n\| = \|\pi(u)^n\| \leq \|u^n\|_\mu = \sqrt{1 + n\mu(\mathbb{T})}.
\]
On the other hand, let \(f \in \mathcal{J}\) be an outer function. So
\[
(\lambda \pi(1) - \pi(u))^{-1} = (1/f(\lambda))\pi(L_\lambda(f)), \quad \lambda \in \mathbb{D}.
\]
Since \(f \in H^\infty\) is outer, for all \(\varepsilon > 0\), \(1/|f(\lambda)| = O(e^{\varepsilon(1-|\lambda|)})\) as \(|\lambda| \rightarrow 1-\). Therefore,
\[
\|(\lambda I - T)^{-1}\| = O\left(\exp \frac{\varepsilon}{1 - |\lambda|}\right), \quad |\lambda| \rightarrow 1-,
\]
where \(I\) is the identity operator. On the other hand, by Cauchy inequality, see [2, Lemma 2], for all \(\varepsilon > 0\)
\[
\|T^{-n}\| = O(e^{\varepsilon\sqrt{n}}), \quad n \rightarrow +\infty.
\]
Therefore the operator \(T\) is invertible, \(\sigma(T) = \{1\}\) satisfies (3) and (4), then it follows from Phragmén Lindelöf principle [2, Corollary 1], that \((I - T)^2 = 0\), which means that \((1 - z)^2 \in \mathcal{J}\).

Let a functional \(\ell\) in the dual space of \(D(\mu) \cap H^\infty\) be such that \(\ell\) is orthogonal to \(J\). We have
\[
\langle \ell, z^n(1 - z)^2 \rangle = 0, \quad n \geq 0.
\]
Let \( \hat{\ell}(n) = \langle \ell, z^n \rangle \), the last equality implies that
\[
\hat{\ell}(n) - 2\hat{\ell}(n + 1) + \hat{\ell}(n + 2) = 0 \quad n \geq 0.
\]

So \( \hat{\ell}(n) = (a + bn) \) for some constants \( a, b \in \mathbb{C} \). In the other hand
\[
|\hat{\ell}(n)| \leq \|\ell\| \|z^n\|_{D(\mu) \cap H^\infty} = O(\sqrt{n}).
\]

Hence \( b = 0 \) and \( \langle \ell, (1 - z) \rangle = 0 \). Which gives \( 1 - z \in \mathcal{J} \) and completes the proof. \( \square \)

**Remark.** The preceding result can be extended to closed ideals such that their greatest common inner divisor is 1.

5. **Cyclicity in \( D(\mu) \)**

**Lemma 5.1.** Let \( f \in D(\mu) \cap H^\infty \) be an outer function. If \( \overline{Z}(f) \cap \text{supp}(\mu) = \emptyset \) then \( f \) is cyclic for \( D(\mu) \).

**Proof.** Suppose that \( \|f\|_\infty \leq 1 \). Since \( \overline{Z}(f) \cap \text{supp}(\mu) = \emptyset \), there exists a closed neighborhood \( V \) of \( \text{supp} \mu \) such that \( \overline{Z}(f) \cap V = \emptyset \). Consider the following outer functions
\[
|h(\zeta)| = \begin{cases} 
1, & \text{on } V, \\
|f(\zeta)|, & \text{a.e. on } \mathbb{T} \setminus V,
\end{cases}
\]

and
\[
|g(\zeta)| = \begin{cases} 
|f(\zeta)|, & \text{a.e. on } V, \\
1, & \text{on } \mathbb{T} \setminus V.
\end{cases}
\]

By Lemma 4.1, \( h, g \in D(\mu) \cap H^\infty \) and by Theorem 2.4
\[
[f]_{D(\mu)} = [hg]_{D(\mu)} = [h]_{D(\mu)} \cap [g]_{D(\mu)}.
\]

Note that \( \overline{Z}(g) = \overline{Z}(f) \cap V = \emptyset \). Hence \( |g(\zeta)| \geq c > 0 \) on \( \mathbb{D} \), and then by Theorem 2.2, \( g \) is cyclic for \( D(\mu) \). So
\[
[f]_{D(\mu)} = [h]_{D(\mu)}. \tag{5}
\]

Let \( \delta > 0 \), and consider the following outer function
\[
|h_\delta(\zeta)| = \begin{cases} 
1, & \text{on } V, \\
1/\sqrt{|f(\zeta)| + \delta}, & \text{a.e. on } \mathbb{T} \setminus V,
\end{cases}
\]

We have \( \lim_{\delta \to 0} |h_\delta h(\zeta)| = 1 \) a.e on \( \mathbb{T} \). Since \( \overline{Z}(f) \cap \text{supp}(\mu) = \emptyset \), by Lemma 4.1
\[
D_\mu(h_\delta h(\zeta)) \leq \frac{1}{\text{dist}(\text{supp} \mu, \mathbb{T} \setminus V)^2 \left( \mu(\mathbb{T}) + 2 \left\| \log \frac{|f| + \delta}{|f|} \right\|_{L^1(\mathbb{T})} \right)}
\]
\[
\leq \frac{1}{\text{dist}(\text{supp} \mu, \mathbb{T} \setminus V)^2 \left( \mu(\mathbb{T}) + 4 \| \log |f| \|_{L^1(\mathbb{T})} \right)}.
\]

So
\[
\liminf_{\delta \to 0} D_\mu(h_\delta h) < \infty.
\]

Since \( h_\delta \) and \( h \) are outer, \( |h_\delta h(z)| \leq |h(z)|/\delta \) for \( z \in \mathbb{D} \), by Theorem 2.2, we have \( h_\delta h \in [h]_{D(\mu) \cap H^\infty} \) for all \( \delta > 0 \). So \( h \) is cyclic for \( D(\mu) \) and by (5) \( f \) is also cyclic for \( D(\mu) \).
Lemma 5.2. Let $f \in \mathcal{D}(\mu) \cap H^\infty$ be outer function. Then
\[
\mathcal{Z}([f]_{\mathcal{D}(\mu)}) \subset \mathcal{Z}(f) \cap \text{supp}(\mu).
\]

Proof. Let $\zeta \in \mathcal{Z}(f) \setminus \text{supp}(\mu)$, there exists an open neighborhood $V_\zeta$ of $\zeta$ such that $V_\zeta \cap \text{supp}(\mu) = \emptyset$. Write
\[
f = f_1 \times f_2, \quad f_1, f_2 \in \mathcal{D}(\mu) \cap H^\infty,
\]
where $\mathcal{Z}(f_2) \subset \mathbb{T} \setminus V_\zeta$ and $\mathcal{Z}(f_1) \subset \overline{V_\zeta}$, so $\mathcal{Z}(f_1) \cap \text{supp}(\mu) = \emptyset$. By Proposition 5.1, $f_1$ is cyclic for $\mathcal{D}(\mu)$. So
\[
[f]_{\mathcal{D}(\mu)} = [f_1 f_2]_{\mathcal{D}(\mu)} = [f_1]_{\mathcal{D}(\mu)} \cap [f_2]_{\mathcal{D}(\mu)} = [f_2]_{\mathcal{D}(\mu)}.
\]
Hence $\zeta \notin \mathcal{Z}([f]_{\mathcal{D}(\mu)})$.
\[
\square
\]

Lemma 5.3. Let $f \in \mathcal{D}(\mu)$ be an outer function. Then
\[
(1) \quad \mathcal{Z}(f) = \mathcal{Z}(f \wedge 1)
\]
\[
(2) \quad [f]_{\mathcal{D}(\mu)} = [f \wedge 1]_{\mathcal{D}(\mu)}
\]
\[
(3) \quad \mathcal{Z}([f]_{\mathcal{D}(\mu)}) = \mathcal{Z}([f]_{\mathcal{D}(\mu)} \cap H^\infty)
\]

Proof. (1) is obvious. (2) is a particular case of Theorem 2.4. (3) follows from (1) and (2).
\[
\square
\]

Proof Theorem 1. If $f$ is cyclic for $\mathcal{D}(\mu)$, then it’s clear that $f$ is an outer function and $c_\mu(\mathcal{Z}_T(f)) = \emptyset$.

Conversely, let $f \in \mathcal{D}(\mu)$ be outer function, since $c_\mu(\mathcal{Z}_\mathbb{T}(f \wedge 1)) = c_\mu(\mathcal{Z}_\mathbb{T}(f))$, by Lemma 5.3, we can suppose that $f \in H^\infty$.

Now suppose $c_\mu(\mathcal{Z}_\mathbb{T}(f)) = 0$, then by Lemma 5.2 we have
\[
\mathcal{Z}([f]_{\mathcal{D}(\mu)}) \subset \text{supp}(\mu \cap \mathcal{Z}(f)).
\]

If $\mathcal{Z}([f]_{\mathcal{D}(\mu)}) = \emptyset$. By Lemma 5.3, $\mathcal{Z}([f]_{\mathcal{D}(\mu)} \cap H^\infty) = \emptyset$ and by Theorem 4.3, $\sigma(\pi(u)) = \emptyset$ where $u : z \to z$ is identity map and $\pi$ the canonical projection associated with $[f]_{\mathcal{D}(\mu)} \cap H^\infty$. Then $f$ is cyclic and the Theorem is proved.

Suppose now that
\[
\mathcal{Z}([f]_{\mathcal{D}(\mu)}) \neq \emptyset.
\]
We will show that this leads to a contradiction. Since $\mathcal{Z}([f]_{\mathcal{D}(\mu)})$ is a countable set, $\mathcal{Z}([f]_{\mathcal{D}(\mu)})$ have an isolated point, noted by $\zeta_0$. Let $V = (e^{ia}, e^{ib})$ be a neighborhood of $\zeta_0$ such that $V \cap \mathcal{Z}([f]_{\mathcal{D}(\mu)}) = \{\zeta_0\}$. Consider the outer functions $h = f_V$ and $g = f_{\mathbb{T} \setminus V}$:
\[
|h(\zeta)| = \begin{cases} 
|\zeta - e^{ia}|(e^{ib} - \zeta)||f(\zeta)|, & \text{a.e. on } \overline{V}, \\
|\zeta - e^{ia}|(e^{ib} - \zeta), & \text{on } \mathbb{T} \setminus \overline{V},
\end{cases}
\]
and
\[
|g(\zeta)| = \begin{cases} 
|\zeta - e^{ia}|(e^{ib} - \zeta)|, & \text{on } \overline{V}, \\
|\zeta - e^{ia}|(e^{ib} - \zeta)||f(\zeta)|, & \text{a.e. on } \mathbb{T} \setminus \overline{V}.
\end{cases}
\]
By Lemma 4.2, \( h, g \in \mathcal{D}(\mu) \cap H^\infty \) and \( hg \in [f]_{\mathcal{D}(\mu)} \). Define the closed division ideal \( \mathcal{J} \) by

\[
\mathcal{J} := \{ \psi \in \mathcal{D}(\mu) \cap H^\infty : \psi g \in [f]_{\mathcal{D}(\mu)} \}.
\]

Since \([f]_{\mathcal{D}(\mu)} \cap H^\infty \subset \mathcal{J} \) and \( h \in \mathcal{J} \),

\[
\mathcal{Z}(\mathcal{J}) \subset \mathcal{Z}([f]_{\mathcal{D}(\mu)}) \cap \mathcal{Z}(h) \subset \{ \zeta_0 \}.
\]

Hence by Lemma 4.4, \( z - \zeta_0 \in \mathcal{J} \) (In fact, if \( \mathcal{Z}(\mathcal{J}) = 0 \) then \( \mathcal{J} = \mathcal{D}_\mu \) and then \((z - \zeta_0)g \in [f]_{\mathcal{D}(\mu)} \). Since by Theorem 2.4, we have \([z - \zeta_0]g_{\mathcal{D}(\mu)} = [(z - \zeta_0)]_{\mathcal{D}(\mu)} \cap [g]_{\mathcal{D}(\mu)} \). We get

\[
[(z - \zeta_0)]_{\mathcal{D}(\mu)} \cap [g]_{\mathcal{D}(\mu)} \subset [f]_{\mathcal{D}(\mu)}.
\]

Now we distinguish 2 cases.

- If \( c_\mu(\{ \zeta_0 \}) = 0 \), then \( z - \zeta_0 \) is cyclic and hence \( g \in [f]_{\mathcal{D}(\mu)} \).
- If \( c_\mu(\{ \zeta_0 \}) > 0 \), since \( c_\mu(\mathcal{Z}(f)) = 0 \), then \( \zeta_0 \notin \mathcal{Z}(f) \) and by Lemma 3.2, \( h(\zeta_0) \) exists and \( h(\zeta_0) \neq 0 \). Note also that \( g(\zeta_0) \) exists, indeed \( |g(\zeta)| = |f_{\mathcal{T}}(\zeta)| = |(\zeta - e^{ia})(\zeta - e^{ib})| \) on \( V \), so the outer function \( g \) can be continued holomorphically across \( V \), see [9, p. 65]. Now write

\[
g = \frac{h}{h(\zeta_0)}g + \frac{h(\zeta_0) - h}{h(\zeta_0)}g \in [f]_{\mathcal{D}(\mu)}.
\]

In the two cases \( g \in [f]_{\mathcal{D}(\mu)} \) which gives a contradiction since and \( \zeta_0 \notin \mathcal{Z}([f]_{\mathcal{D}(\mu)}) \) and \( g(\zeta_0) \neq 0 \). Thus we have completed the proof of the first main result.

6. INVARIANT SUBSPACES OF \( \mathcal{D}(\mu) \)

This section is devoted to the proof of Theorem 2. Let \( \mathcal{M} \in \text{Lat}(S, \mathcal{D}(\mu)) \) be a closed invariant subspace of \( \mathcal{D}(\mu) \). By Theorem 2.6, there exists an inner function \( \Theta_\mathcal{M} \) and an outer function \( f \in \mathcal{D}(\mu) \cap H^\infty \) such that

\[
\mathcal{M} = \Theta_\mathcal{M}H^2 \cap [f]_{\mathcal{D}(\mu)}.
\]

We need to show that

\[
[f]_{\mathcal{D}(\mu)} = \mathcal{M}_\mu(E),
\]

here \( \mathcal{M}_\mu(E) \) be the closed invariant subspace of \( \mathcal{D}(\mu) \) given by

\[
\mathcal{M}_\mu(E) = \{ \psi \in \mathcal{D}(\mu) : \psi|E = 0 \},
\]

where \( E = \{ \lambda \in \text{supp} \mu : c_\mu(\{ \lambda \}) > 0 \text{ and } \lambda \notin \mathcal{Z}(\mathcal{M}) \} \).

Note that if \( \lambda \in \text{supp} \mu \) such that \( c_\mu(\{ \lambda \}) > 0 \) then

\[
\lambda \in \mathcal{Z}(\mathcal{M}) \iff \lambda \in \mathcal{Z}(f).
\]

Let \( \psi \in [f]_{\mathcal{D}(\mu)} \), and let \( \lambda \in E \), since \( c_\mu(\{ \lambda \}) > 0 \), the evaluation is continuous and by Lemma 3.2, \( \psi(\lambda) \) exists and \( \psi(\lambda) = 0 \). So \( \psi \in \mathcal{M}_\mu(E) \) and we have \([f]_{\mathcal{D}(\mu)} \subset \mathcal{M}_\mu(E)\).
Now we show the opposite inclusion. By Theorem 2.5, there exists an outer function \( \phi \in \mathcal{M}_\mu(E) \cap H^\infty \) such that \( \mathcal{M}_\mu(E) = [\phi]_{\mathcal{D}(\mu)} \). Consider the closed division ideal

\[
\mathcal{J} = \{ \psi \in \mathcal{D}(\mu) \cap H^\infty : \psi \phi \in [f]_{\mathcal{D}(\mu)} \}.
\]

We have \([f]_{\mathcal{D}(\mu)} \cap H^\infty \subset \mathcal{J}\) and by Lemmas 5.2 and 5.3 (3)

\[
\mathcal{Z}(\mathcal{J}) \subset \mathcal{Z}(f) \cap \text{supp } \mu.
\]

- If \( \mathcal{Z}(\mathcal{J}) = \emptyset \), then by Theorem 4.3, we get \( \mathcal{J} = \mathcal{D}(\mu) \cap H^\infty \).

- If \( \mathcal{Z}(\mathcal{J}) \neq \emptyset \). Since \( \text{supp } \mu \) is countable, the set \( \mathcal{Z}(\mathcal{J}) \) has an isolated point \( \zeta_0 \). Let \( V = (e^{iu}, e^{ib}) \) be a neighborhood of \( \zeta_0 \) such that \( \mathcal{V} \cap \mathcal{Z}(\mathcal{J}) = \{ \zeta_0 \} \). Consider again the outer functions \( h = f_V \) and \( g = f_{T \setminus V} \) as in Lemma 4.2. By Lemma 4.2, \( g, h \in \mathcal{D}(\mu) \cap H^\infty \).

Now let

\[
\tilde{\mathcal{J}} := \{ \psi \in \mathcal{D}(\mu) \cap H^\infty : \psi g \in \mathcal{J} \}.
\]

We have \( h \in \tilde{\mathcal{J}} \), so \( \mathcal{Z}(\tilde{\mathcal{J}}) \subset V \). Also \( \mathcal{J} \cap H^\infty \subset \tilde{\mathcal{J}} \), hence \( \mathcal{Z}(\tilde{\mathcal{J}}) \subset \mathcal{Z}(\mathcal{J}) \cap V = \{ \zeta_0 \} \).

Since \( h \) is an outer function, by Lemma 4.4, \( (z - \zeta_0)g \phi \in [f]_{\mathcal{D}(\mu)} \).

As before we distinguish 2 cases.

- If \( c_\mu(\{\zeta_0\}) = 0 \), then \( z - \zeta_0 \) is cyclic. Hence \( g \phi \in [f]_{\mathcal{D}(\mu)} \).

- If \( c_\mu(\{\zeta_0\}) > 0 \), we distinguish again 2 cases.

  - if \( f(\zeta_0) = 0 \) then \( \zeta_0 \in E \), \( \mathcal{M}_\mu(E) \subset \mathcal{M}_\mu(\{\zeta_0\}) \) and

    \[
    ([z - \zeta_0] \phi)_{\mathcal{D}(\mu)} = ([z - \zeta_0] \phi)_{\mathcal{D}(\mu)} \cap [\phi]_{\mathcal{D}(\mu)} = \mathcal{M}_\mu(E) = [\phi]_{\mathcal{D}(\mu)}.
    \]

    So

    \[
    [g \phi]_{\mathcal{D}(\mu)} = [g]_{\mathcal{D}(\mu)} \cap [\phi]_{\mathcal{D}(\mu)} = [g]_{\mathcal{D}(\mu)} \cap ([z - \zeta_0] \phi)_{\mathcal{D}(\mu)} = ([z - \zeta_0]g \phi)_{\mathcal{D}(\mu)} \subset [f]_{\mathcal{D}(\mu)}.
    \]

  - if \( f(\zeta_0) \neq 0 \) then \( h(\zeta_0) = f_V(\zeta_0) \neq 0 \) and \( h \in \tilde{\mathcal{J}} \). As before

    \[
    g \phi = \frac{h}{h(\zeta_0)}g \phi + \frac{h(\zeta_0) - h}{h(\zeta_0)}g \phi \in [f]_{\mathcal{D}(\mu)}.
    \]

In all cases we have \( g \phi \in [f]_{\mathcal{D}(\mu)} \). We get, as before in the proof of Theorem 1, that \( \mathcal{D}(\mu) \cap H^\infty = \tilde{\mathcal{J}} \) and

\[
\mathcal{M}_\mu(E) \subset [f]_{\mathcal{D}(\mu)}.
\]

Now the proof is complete. \( \square \)
7. Final remarks

- Note that if $\mu$ is a positive finite measure such that $\text{supp} \mu \subset E_1 \cup E_2$, where $E_1$ and $E_2$ are disjoint closed subsets of $\mathbb{T}$, then $\mathcal{D}(\mu) = \mathcal{D}(\mu|_{E_1}) \cap \mathcal{D}(\mu|_{E_2})$. In this case every closed invariant subspace $\mathcal{M}$ of $\mathcal{D}(\mu)$ can be written as $\mathcal{M} = \mathcal{M}_1 \cap \mathcal{M}_2$, where $\mathcal{M}_i$ is an invariant subspace of $\mathcal{D}(\mu|_{E_i})$ ($i = 1, 2$).

- A closed set $E$ is union of a countable set and perfect set. Using the same argument as in the proof of Theorem 1, one can prove that Brown-Shields conjecture is true for $\mathcal{D}(\mu)$ if and only if Brown-Shields conjecture is true for $\mathcal{D}(\mu|_{\mathcal{P}(\text{supp} \mu)})$ where $\mathcal{P}(\text{supp} \mu)$ is the perfect core of the support of $\mu$.

Acknowledgments. The authors are grateful to the referee for his valuable remarks and suggestions.
