Ablation of the N-type calcium channel ameliorates diabetic nephropathy with improved glycemic control and reduced blood pressure

Shoko Ohno1, Hideki Yokoi1, Kiyoshi Mori2, Masato Kasahara3, Koichiro Kuwahara4, Junji Fujikura5, Masaki Naito5, Takashige Kuwabara1,6, Hirotaka Imamaki5, Akira Ishii1, Moin A. Saleem7, Tomohiro Numata8,9, Yasuo Mori8, Kazuwa Nakao1, Motoko Yanagita1 & Masashi Mukoyama1,6

Pharmacological blockade of the N- and L-type calcium channel lessens renal injury in kidney disease patients. The significance of specific blockade of α1 subunit of N-type calcium channel, CaV2.2, in diabetic nephropathy, however, remains to be clarified. To examine functional roles, we mated CaV2.2−/− mice with db/db (diabetic) mice on the C57BLKS background. CaV2.2 was localized in glomeruli including podocytes and in distal tubular cells. Diabetic CaV2.2−/− mice significantly reduced urinary albumin excretion, glomerular hyperfiltration, blood glucose levels, histological deterioration and systolic blood pressure (SBP) with decreased urinary catecholamine compared to diabetic CaV2.2+/+ mice. Interestingly, diabetic heterozygous CaV2.2+/− mice also decreased albuminuria, although they exhibited comparable systolic blood pressure, sympathetic nerve activity and creatinine clearance to diabetic CaV2.2+/+ mice. Consistently, diabetic mice with cilnidipine, an N-/L-type calcium channel blocker, showed a reduction in albuminuria and improvement of glomerular changes compared to diabetic mice with nitrendipine. In cultured podocytes, depolarization-dependent calcium responses were decreased by ω-conotoxin, a CaV2.2-specific inhibitor. Furthermore, reduction of nephrin by transforming growth factor-β (TGF-β) in podocytes was abolished with ω-conotoxin, cilnidipine or mitogen-activated protein kinase kinase inhibitor. In conclusion, CaV2.2 inhibition exerts renoprotective effects against the progression of diabetic nephropathy, partly by protecting podocytes.

Diabetic nephropathy is the most common cause of end-stage renal failure1. To prevent the progression of diabetic nephropathy, a strict blood pressure control is strongly recommended1. Although renin-angiotensin system (RAS) inhibitors are extensively used as first-choice drugs for diabetic nephropathy2,3, the effects of other antihypertensive drugs on diabetic nephropathy remain elusive4.

Calcium channel blockers (CCBs) are frequently used in combination with RAS inhibitors because of their strong blood pressure-lowering properties and minimal adverse side effects5. The voltage-dependent calcium

channels are localized in the plasma membrane and are essential for the release of neurotransmitters and hormones. These channels are classified into L-, P/Q-, N-, R-, and T-type subtypes based on their pharmacological and electrophysiological properties. Molecular biological analysis has shown that calcium channels are composed of α1, α2δ, β, and γ subunits, among which α1 subunits are most important for defining channel properties. The α1 subunit genes have been cloned and classified into the following three subfamilies based on their sequence similarity: Ca1.1x, Ca1.2x, and Ca1.3x. The α1b subunit Ca1.2, encoded by the CACNA1B gene, is the only subunit which constitutes the N-type calcium channel.

Cilnidipine is an L-/N-type CCB which is used for patients with hypertension. In several clinical and basic studies, cilnidipine has been shown to reduce proteinuria compared with other antihypertensive drugs. The CARTER study demonstrated that the L-/N-type CCB cilnidipine, but not the L-type CCB amiodipine, decreases urinary protein levels in RAS inhibitor-treated hypertensive patients with macroproteinuria. The renoprotective effects of L-/N-type CCBs are at least partly due to the amelioration of glomerular hypertension. L-type CCBs elicit afferent arteriole-prone vasodilation, which may increase the intraglomerular pressure. On the other hand, L-/N-type CCBs ameliorate glomerular hypertension through the vasodilation of both afferent and efferent arterioles.

The N-type calcium channel α1 subunit knockout (Ca1.2−/−) mice, which lack the cytosolic portion of the N-type calcium channel, are viable and have an almost normal behavior but show a very low sympathetic nerve activity in atria. Although previous reports used cilnidipine to inhibit N- and L-type calcium channel in diabetic nephropathy, molecular mechanisms of specific N-type calcium channel blockade in glomerular injury are not fully investigated. To address these questions, we investigated renal injury in N-type calcium channel-deficient db/db mice on the diabetes-prone C57BLKS/J background. In addition, we examined the functional role of N-type calcium channel in cultured podocytes.

Results
Characteristics of Diabetic Ca1.2−/− Mice. To examine the role of the N-type calcium channel in diabetic nephropathy, we crossed Ca1.2−/− mice with db/m mice on the C57BLKS/J background more than six times to obtain db/db Ca1.2−/− mice. All diabetic (db/db) mouse groups showed significantly increased body weights compared with those of non-diabetic (db/+ ) controls, and db/db Ca1.2−/− mice tended to have a heavier body weight than other db/db mouse groups (Fig. 1a). db/db Ca1.2+/+ mice showed renal hypertrophy, as indicated by an increase in kidney weight, whereas db/db Ca1.2−/− mice exhibited less renal hypertrophy (Fig. 1b). We measured the systolic blood pressure (SBP) of db/+ mice at 8, 12, and 16 weeks of age. db/+ Ca1.2−/− mice showed lower SBP than db/+ Ca1.2+/+ mice at 8 weeks of age, and the difference disappeared at 12 and 16 weeks of age (Fig. 1c). On the other hand, the SBP of db/db Ca1.2−/− mice remained 15–20 mmHg lower than that of db/db Ca1.2+/+ mice during the experimental period (Fig. 1d). These results indicate that the deficiency of Ca1.2 resulted in reduction of basal SBP. To evaluate the mechanism of SBP reduction, we measured urinary catecholamines. db/db Ca1.2−/− mice, but not db/db Ca1.2+/+ mice, exhibited 50% lower levels of urinary noradrenaline and adrenaline than db/db Ca1.2+/+ mice (Fig. 1e,f).

Improvement of Glucose Metabolism in Ca1.2−/− Mice. To examine glucose metabolism in db/db Ca1.2−/− mice, we analyzed 6-h fasting blood glucose levels every 2 weeks during the experimental period. All db/db mouse groups showed hyperglycemia at 8 weeks of age, whereas all db/+ mouse groups had normal glucose levels (Fig. 2a). Notably, db/db Ca1.2−/− mice had or tended to have lower levels of blood glucose than db/db Ca1.2+/+ mice during the experimental period (Fig. 2a). Sixteen-hour fasting serum insulin levels were not different among db/db mouse groups at 16 weeks of age (Fig. 2b). Intraparenchymal glucose tolerance tests (IPGTTs) were performed to further evaluate glucose metabolism at 15 weeks of age. The blood glucose levels in GTTs peaked at 30 min were 250 mg/dL in db/+ Ca1.2−/− mice and 400 mg/dL in db/+ Ca1.2+/+ mice, indicating better glucose tolerance in db/+ Ca1.2−/− mice than that in db/+ Ca1.2+/+ mice (Fig. 2c). db/db Ca1.2−/− mice developed severe glucose intolerance, whereas db/db Ca1.2+/+ mice exhibited significantly reduced blood glucose levels compared with those in db/db Ca1.2+/+ mice (Fig. 2d). The level of HbA1c was also reduced in db/db Ca1.2−/− mice compared with db/db Ca1.2+/+ mice (Fig. 2e). Serum insulin levels of db/db mouse groups in GTTs were increased compared with those of db/+ mouse groups (Fig. 2f). There was no significant difference among db/+ mouse groups. On the other hand, the insulin levels in db/db Ca1.2+/+ and db/db Ca1.2−/− mice were significantly higher than those of db/db Ca1.2+/+ mice, suggesting that insulin secretion increased in mice with Ca1.2 gene deletion.

Insulin tolerance tests (ITTs) were performed to determine whether the improved glucose tolerance observed in Ca1.2−/− mice was associated with increased insulin sensitivity. Ca1.2−/− mice showed lower glucose levels than Ca1.2+/+ mice in both db/+ and db/db genotypes after insulin injection (Fig. 2g,h). These results indicate that deficiency of Ca1.2 improves insulin secretion and insulin sensitivity in diabetic conditions.

Reduced Urinary Albumin Excretion and Improved Hyperfiltration in Diabetic Ca1.2−/− Mice. To evaluate the functional alterations in the kidney of diabetic Ca1.2−/− mice, we examined urinary albumin excretion and serum creatinine level and calculated creatinine clearance (CCr). At baseline, there were no significant differences in urinary albumin excretion between db/+ Ca1.2−/− and db/+ Ca1.2+/+ mice (Fig. 3a). Urinary albumin excretion markedly increased in db/db Ca1.2−/− mice at 8 weeks of age. In contrast, db/db Ca1.2+/+ mice exhibited approximately 70% lower urinary albumin excretion than db/db Ca1.2−/− mice. Interestingly, db/db Ca1.2+−/− mice also exhibited decreased albuminuria to the level comparable to that of db/db Ca1.2−/− mice (Fig. 3a). These results suggest that even a partial ablation of the N-type calcium channel leads to reduction in urinary albumin excretion.
Next, we examined the effect of N-type calcium channel ablation on hyperfiltration induced by diabetic milieu by measuring CCr. Basal levels of serum creatinine were not different regardless of the genotype of Cav2.2 (Fig. 3b).

db/db Cav2.2−/+ mice showed a reduction of serum creatinine levels compared with those in db/+ Cav2.2−/+ mice, thus indicating hyperfiltration in diabetic states (Fig. 3b). Although diabetic Cav2.2−/+ mice
Figure 2. Blood glucose, serum insulin, and the results of GTTs and ITTs in db/+ and db/db mice. (a) Time course of 6-h fasting blood glucose concentrations. db/db Cav2.2−/+ mice had lower levels of blood glucose than db/db Cav2.2−/− mice. (b) Serum insulin levels at 16 weeks of age. There were no different among db/db mice groups. (c) IPGTTs (2 g/kgBW) of db/+ mice at 15 weeks of age. db/+ Cav2.2−/+ mice showed better glucose tolerance compared with db/+ Cav2.2−/− mice. (d) IPGTTs (1 g/kgBW) of db/db Cav2.2−/− mice at 15 weeks of age. db/db Cav2.2−/− mice exhibited significantly reduced levels of blood glucose compared with db/db Cav2.2+/+ mice. Since the glucometer has a detection limit up to 999 mg/dL, values above the detection limit were treated as 1000 mg/dL. (e) Hemoglobin A1c levels at 16 weeks of age. (f) Serum insulin levels of IPGTTs. The insulin levels in db/db Cav2.2−/− mice was significantly higher than these of db/db Cav2.2+/+ mice. (g) Blood glucose levels in ITTs at 15 weeks of age of db/+ (g) and db/db (h) mice. db/+ Cav2.2−/− mice (n = 5, white circles), db/+ Cav2.2+/+ mice (n = 9, white triangles), db/+ Cav2.2−/− mice (n = 7, white squares), db/db Cav2.2−/− mice (n = 9, black circles), db/db Cav2.2+/+ mice (n = 8, black squares) for GTT. (h) Blood glucose levels in ITTs at 15 weeks of age of db/+ (g) and db/db (h) mice. db/+ Cav2.2−/− mice (n = 5, white circles), db/+ Cav2.2+/+ mice (n = 9, white triangles), db/+ Cav2.2−/− mice (n = 7, white squares), db/db Cav2.2−/− mice (n = 9, black circles), db/db Cav2.2+/+ mice (n = 9, black triangles), and db/db Cav2.2−/− mice (n = 7, black squares) for ITT. *p < 0.05, **p < 0.01 compared with Cav2.2+/+ mice of the same db genotype.
exhibited CCr elevation because of hyperfiltration, the increase in CCr was almost completely abolished in db/db Cav2.2−/− mice, suggesting that hyperfiltration was normalized by deletion of the Cav2.2 gene (Fig. 3c).

N-type Calcium Channel Expression in Glomeruli of Control Mice and Renal Histological Improvement in Diabetic Ca2.2−/− Mice. N-type calcium channel localization was examined by an immunohistochemical study. Ca2.2 was expressed in tubules and glomerular cells in the kidney of both db/+ Ca2.2+/+ and db/db Ca2.2+/− mice (Fig. 3d). Double immunohistochemical staining showed that cells positive for Ca2.2 in a glomerulus were also positive for WT1, a podocyte marker, indicating that Ca2.2 is expressed in podocytes (Fig. 3e).

Figure 3. Role of Ca2.2 on diabetic nephropathy. (a) Time course of urinary albumin excretion per milligram creatinine of experimental mice. Urinary albumin excretion of both db/db Ca2.2−/− mice and db/db Ca2.2+/− mice was lower than that of db/db Ca2.2+/+ mice. (b) Serum creatinine levels at 16 weeks of age. (c) Creatinine clearance at 16 weeks of age. In db/db Ca2.2+/+ mice, creatinine clearance was suppressed to the same level of db/+ mice. (d) Immunohistochemical study of Ca2.2 in db/+ Ca2.2+/+ and db/db Ca2.2+/− mice. Ca2.2 was positive at glomerular cells (arrows). (e) Double immunostaining for Ca2.2 (brown) and WT1 (blue) shows double positive cells in a glomerulus (insets). db/+ Ca2.2+/+ mice (black circles), db/db Ca2.2+/− mice (black triangles), and db/db Ca2.2−/− mice (black squares). *p < 0.05, **p < 0.01, vs. db/db Ca2.2+/+ mice. Scale bar = 50 μm.
We examined renal histology at 16 weeks of age. We observed mesangial expansion with glomerular hypertrophy in db/db Ca,2.2^{+/+} mice, which was consistent with diabetic alterations (Fig. 4a). In contrast, db/db Ca,2.2^{-/-} mice exhibited reduced glomerular mesangial expansion and inhibited glomerular hypertrophy compared with those seen in db/db Ca,2.2^{+/+} mice (Fig. 4a). db/db Ca,2.2^{+/+} mice also showed ameliorated glomerular changes.

Figure 4. Histologic examination of a glomerulus. (a) Light microscopic analyses were performed at 16 weeks of age, stained with periodic acid–Schiff. db/db Ca,2.2^{+/+} mice showed reduced mesangial expansion compared with db/db Ca,2.2^{+/+} mice. Scale bar = 50 μm. (b) Mesangial area in a glomerulus at 16 weeks of age. Mesangial area was increased in db/db Ca,2.2^{+/+} mice and was suppressed in db/db Ca,2.2^{-/-} mice. (c) Immunostaining for nephrin and podocin. db/db Ca,2.2^{-/-} mice maintained nephrin and podocin to the same level with db/+ mice. Scale bar = 50 μm. (d,e) Electron microscopic analyses of glomeruli of experimental mice at 16 weeks of age. GBM thickness was ameliorated in db/db Ca,2.2^{-/-} mice. Scale bar = 500 nm. **p < 0.01, vs. db/db Ca,2.2^{+/+} mice.
Morphometric analysis revealed that the mesangial area was increased in db/db Cav2.2+/+ mice, whereas this increase was significantly suppressed in both db/db Cav2.2−/− and db/db Cav2.2+/− mice (Fig. 4b). These results suggest that N-type calcium channel ablation can limit the progression of diabetic nephropathy. Next, we evaluated podocyte injury in these mice. Immunostaining of nephrin and podocin, expressed predominantly in podocytes, was markedly decreased in db/db Cav2.2+/+ mice compared with that in db/+ Cav2.2+/+ mice (Fig. 4c). In contrast, db/db Cav2.2−/− mice maintained the expression of nephrin and podocin to the same level as db/+ mice, indicating the amelioration of podocyte injury (Fig. 4c). In electron microscopic analysis, db/db Cav2.2+/+ mice showed thickening of the glomerular basement membrane (GBM) with slightly widened podocyte foot processes (Fig. 4d,e). GBM thickening was significantly ameliorated in db/db Cav2.2−/− mice (Fig. 4e).

Glomerular Gene Expression and Phosphorylation of Extracellular Signal-Regulated Kinase (ERK) in Diabetic Ca2,2−/− Mice. Analyses of the glomerular expression of extracellular matrix (ECM)-related genes revealed that TGF-β1 (Tgfb1) mRNA as well as connective tissue growth factor (Ctgf) mRNA were increased in db/db Ca2,2+/+ mice, whose increase was significantly reduced in db/db Ca2,2−/− mice (Fig. 4b). Expression of pro-alpha 3 chain of collagen IV (Col4a3) mRNA was also significantly reduced in db/db Ca2,2−/− mice compared with that in db/+ Ca2,2+/+ mice (Fig. 4c). In contrast, db/db Ca2,2−/− mice maintained the expression of nephrin and podocin to the same level as db/+ mice, indicating the amelioration of podocyte injury (Fig. 4c). In electron microscopic analysis, db/db Ca2,2+/+ mice showed thickening of the glomerular basement membrane (GBM) with slightly widened podocyte foot processes (Fig. 4d,e). GBM thickening was significantly ameliorated in db/db Ca2,2−/− mice (Fig. 4e).

**Figure 5. Analysis of glomerular mRNA expression.** Real-time RT-PCR analyses of glomerular Tgfb1 (a), Ctgf (b) Col4a3 (c) Ca2,1b (d) Ca2,1c (e) and Ca2,1g (f) were shown. Gapdh was used as control. *p < 0.05, **p < 0.01.
α1 subunit of T-type calcium channel was upregulated in diabetic mice, and was not different among diabetic or non-diabetic 3 groups (Fig. 5f).

Activation of extracellular signal-regulated kinase (ERK) has been shown to mediate TGF-β-induced accumulation of ECM protein in diabetic nephropathy18. We found that ERK phosphorylation was increased in glomeruli, including mesangial cells and podocytes, of db/db Cav2.2+/+ mice compared with that of db/db Cav2.2−/− mice (Fig. 6a). Macrophages also play a critical role in the progression of diabetic nephropathy19. The immunohistochemical study showed that macrophage antigen-2 (Mac2)-positive cells in glomeruli increased by 3.0-fold in db/db Cav2.2+/+ mice compared with those in db/+ Cav2.2+/+ mice and suppressed in db/db Cav2.2−/− mice (Fig. 6b,c). This increase was significantly suppressed in db/db Cav2.2−/− mice (Fig. 6b,c).

Pharmacological Inhibition of L- or N-type Calcium Channel Ameliorates Diabetic Nephropathy. To evaluate the pharmacological effect of N-type CCBs, we administered the N-/L-type CCB cilnidipine or the L-type CCB nitrendipine to db/db Cav2.2−/− mice and compared with db/db Cav2.2+/− and db/db Cav2.2−/− mice. There was no significant difference in body weight among vehicle-, nitrendipine-, cilnidipine-treated, db/db Cav2.2+/+ and db/db Cav2.2−/− mouse groups (Supplementary Fig. S2a). Diabetic db/db Cav2.2−/− mice exhibited lower blood glucose level than db/db Cav2.2+/− mouse as shown previously (Fig. 2a, Supplementary Table S1). Diabetic mice with nitrendipine exhibited high urinary noradrenaline and adrenaline excretion, however, diabetic mice with cilnidipine did not change urinary catecholamine levels compared with those with nitrendipine (Supplementary Fig. S2b,c). Administration of nitrendipine or cilnidipine showed SBP almost similar to that in the vehicle and db/db Cav2.2+/− mouse groups (Fig. 1d, Supplementary Fig. S2a). Diabetic db/db Cav2.2−/− mice showed lower SBP than vehicle, nitrendipine-, cilnidipine-treated and db/db Cav2.2+/− mice (Fig. 1d, Supplementary Fig. S3a). Urinary albumin excretion was suppressed in the cilnidipine-treated group and not in the nitrendipine-treated group, however, urinary albumin excretion in cilnidipine-treated mice was still higher than that in db/db Cav2.2+/− mice (Supplementary Fig. S3b). Renal histology showed that treatment with cilnidipine, but not with nitrendipine, inhibited mesangial expansion in diabetic mice to the comparable extent of db/db Cav2.2+/− mice (Supplementary Fig. S3c,d). In electron
microscopic analysis, footprocesses widening and GBM thickening in diabetic mice was ameliorated only by cilnidipine treatment, which was comparable to db/db Ca,2.2−/− mice (Supplementary Fig. S3e,f). Glomerular expression of TGF-β1 (Tgfb1) and connective tissue growth factor (Ctgf) mRNA tended to show a reduction in cilnidipine-treated mice, but the difference was not significant (Supplementary Fig. S4a,b). Accumulation of macrophages was decreased in cilnidipine-treated mice compared with vehicle-treated mice (Supplementary Fig. S4c,d).

The Functional Role of N-type Calcium Channel on Cultured Podocytes. First of all, to examine the role of the N-type calcium channel on podocytes, we measured intracellular Ca2+(Ca2+i) concentration in cultured human podocytes. When podocytes were stimulated with 107 mM KCl, depolarization-dependent [Ca2+i] increase was observed, and this [Ca2+i] concentration was partially abolished by treatment with the N-type calcium channel blocker, ω-conotoxin (Fig. 7a,b). We also found that nifedipine, cilnidipine, or ω-conotoxin plus nifedipine inhibited depolarization-induced [Ca2+i], in cultured podocytes (Fig. 7c,d). These results suggest that both N- and L-type calcium channels are expressed in cultured human podocytes and are relevant to depolarization-induced [Ca2+i], increase.

To confirm the effect of N-type calcium channel blockade on podocytes, we examined the changes in nephrin expression in cultured human podocytes treated with ω-conotoxin. Administration of exogenous TGF-β significantly ameliorated albuminuria without affecting sympathetic nerve function. In addition, we showed no compensatory increase in nephrin expression in podocytes (Fig. 7f). Nitrendipine did not change the TGF-β-induced reduction of nephrin expression, but cilnidipine upregulated nephrin expression in podocytes (Fig. 7f).

Finally, we revealed that inhibition of ERK by mitogen-activated kinase kinase (MEK) inhibitor U0126 significantly ameliorated TGF-β-induced reduction of nephrin expression (Fig. 7g).

Discussion
Investigation of diabetic nephropathy in rodents is rendered difficult partly by the lack of adequate animal models displaying typical diabetic nephropathy20. Among these limited mouse models of diabetic nephropathy, db/db mice are one of the most frequently used disease models. Nevertheless, the genetic background plays an important role in developing diabetic nephropathy; e.g., db/db mice on the C57BLKS background exhibit massive proteinuria and mesangial expansion, whereas db/db mice on the C57BL/6J show less severe glomerular and glycemic changes20–22. Knockout mice are mostly generated on the C57BL/6J or 129/SvJ backgrounds22. In order to overcome these situations, we backcrossed Ca,2.2 knockout mice on the C57BL/6J background with C57/BLKS to explore the role of the N-type calcium channel in diabetic nephropathy.

The present study demonstrated that glycemic control was improved with enhanced insulin secretion in diabetic mice by ablation of the N-type calcium channel. In a previous study, Ca,2.2−/− mice showed lower fasting glucose levels and better glucose tolerance than wild-type mice without any change in insulin sensitivity upon GTT23. The same study reported that, after 10 weeks of high-fat diet feeding, Ca,2.2−/− mice still showed lower fasting glucose levels and better glucose tolerance than Ca,2.2+/+ and Ca,2.2+/− mice. The mechanisms how Ca,2.2 deletion resulted in better glycemic control have not been clarified yet, but another report has shown that the N-type calcium channel is present on pancreatic α cells and that GLP-1 inhibits glucagon release by selectively suppressing this channel24. In our study, db/db Ca,2.2−/− mice showed a marginally improved glucose tolerance; however, the reduction in urinary albumin excretion was much larger than expected from the degree of glycemic control, suggesting that mechanisms other than the amelioration in glucose metabolism would contribute to renoprotective effects, particularly in db/db Ca,2.2+/− mice.

Diabetic Ca,2.2−/− mice showed lower SBP with a marked reduction in urinary catecholamine levels. Similarly, a previous report showed that Ca,2.2−/− mice exhibited lower SBP than control mice because of vasodilatation, reduction of heart contractile activity, and inhibition of sympathetic nerve activity25. Most notably in our study, urinary albumin excretion was reduced by 70% and renal hyperfiltration was normalized in db/db Ca,2.2−/− mice. In addition, even diabetic Ca,2.2+/− mice, in which the expression of the N-type calcium channel is ~50% less than wild-type mice, showed a decrease in albuminuria to the level comparable to that in diabetic Ca,2.2+/− mice. The former denied reduction in sympathetic nerve activity, suggesting that partial inhibition of the N-type calcium channel could ameliorate albuminuria without affecting sympathetic nerve function.

Cilnidipine has been shown to ameliorate glomerular hypertrophy by dilating both afferent and efferent arterioles in the kidney22,16, and L-type calcium channel blockade does not improve glomerular hypertension because the L-type calcium channel blockade mainly dilates afferent arterioles15. Because N-type calcium channels exist at synaptic nerve endings in both the afferent and efferent arterioles, and the blockade of the N-type calcium channel inhibits norepinephrine release26, such sympatholytic effect of the N-type calcium channel ablation may have worked to ameliorate glomerular injury in our study. Cilnidipine showed similar antihypertensive effects and suppression of proteinuria both in innervated and denervated spontaneous hypertensive rat (SHR)27, thus suggesting that renal sympathetic nerves may have a limited contribution to its renoprotective effects. In our study, albuminuria as well as glomerular histological changes were significantly alleviated in db/db Ca,2.2+/− mice and cilnidipine-treated diabetic mice without reduction of urinary catecholamine levels, further providing a possibility for mechanisms independent of the sympathetic nerve activity. In addition, we showed no compensatory expression of α1 subunits of L- and T-type calcium channel in Ca,2.2 heterozygous or knockout mice. Further study is necessary to distinguish the effects of N- and T-type calcium channel blocker, because blockade of T-/L-type calcium channel by manidipine28 or efonidipine29 exhibit similar effects as N-/L-type calcium channel blocker, cilnidipine, in terms of amelioration of glomerular hypertension.

As diabetic N-type calcium channel knockout mice improved metabolic parameters including glycemic control and blood pressure, the amelioration of diabetic renal injury in N-type calcium channel knockout mice is partly due to simultaneous improvements of metabolic parameters. However, in addition to these actions,
Figure 7. Expression of N-type calcium channels in cultured human podocytes and the functional role of these channels in depolarization-induced Ca\(^{2+}\) response. (a,b) Inhibitory effect of 3 μM ω-conotoxin (black squares) on depolarization-induced Ca\(^{2+}\) responses in human podocyte (n = 27–39) compared with control (white squares). (a) Averaged time courses of depolarization-induced Ca\(^{2+}\) response in human podocyte. (b) The bars represent the differences between the maximum of ration and the value of steady state. *p < 0.05 vs. control. (c,d) Inhibitory effect of 3 μM cilnidipine and 3 μM nifedipine on depolarization-induced Ca\(^{2+}\)
responses in human podocyte (n = 20–30). (e) Averaged time courses of depolarization-induced Ca^{2+} response in human podocyte. 3 μM nifedipine; black squares, 3 μM cilnidipine; black circles, 3 μM ω-conotoxin + 3 μM nifedipine; white circles, DMSO; white squares. (d) The bars represent the differences between the maximum of ratio and the value of steady state. *p < 0.05, **p < 0.01, ***p < 0.001 vs. DMSO. (e) TGF-β1 (20 ng/ml) suppressed NPHS1 expression in cultured human podocytes. Its inhibition was canceled by 100 nM ω-conotoxin. n = 11 for TGF-β (−) groups and n = 12 for TGF-β (+) groups. (f) Cilnidipine (10 μM) not nitrrendipine (10 μM) ameliorated reduction of NPHS1 expression induced by 5 ng/ml TGF-β1 in podocytes. Vehicle (n = 5) and other groups (n = 6, each). *p < 0.05, **p < 0.01. GAPDH was used as control.

we showed possible functional roles of the N-type calcium channel in podocytes. Previous reports showed that glomerular podocytes express the N-type calcium channel13,27. Fan et al. demonstrated the immunoreactivity of N-type calcium channels in kidney vascular walls, possibly in the nerves in adventitia, distal tubules, and podocytes, and that the N-type calcium channel in cultured podocytes was involved in the angiotensin II-induced production of reactive oxygen species45. In the present study, we also found that the N-type calcium channel is expressed in glomeruli, presumably podocytes, in control mice. The genetic inhibition of N-type calcium channels reduced podocyte injury in diabetic mice. In vitro analysis using calcium imaging revealed that N-type calcium channels as well as L-type calcium channels are functional in depolarization-induced [Ca^{2+}]_i increase in cultured human podocytes. Furthermore, we examined the changes in nephrin expression induced by TGF-β stimulation in cultured human podocytes and revealed that the decrease caused by the administration of exogenous TGF-β was canceled by pre-incubation with ω-conotoxin, cilnidipine or MEK inhibitor. High glucose-induced ERK activation in podocytes is closely associated with diabetic nephropathy through the protein kinase C pathway30,31, suggesting that ERK plays an important role in TGF-β-induced podocyte injury.

In conclusion, we have demonstrated that the ablation or blockade of the N-type calcium channel in diabetic mice exerts renoprotective effects, which effects may be brought about by both improvement of metabolic parameters and protection from podocyte injury. These results indicate that the N-type calcium channel works as an aggravating factor in a mouse model of diabetic nephropathy, suggesting a possibility that the N-type calcium channel should provide a promising therapeutic target for preventing the progression of diabetic nephropathy in humans.

Methods

Animals and drug treatment. All animal experiments were approved by the Animal Experimentation Committee of Kyoto University Graduate School of Medicine and were carried out in accordance with the approved guidelines. Mice deficient in the α1B subunit of the N-type calcium channel (Ca_{2.2}^{−/−} mice) were produced on the 129/SvJ background13 and then backcrossed with C57BL/6J mice more than 10 times. BKS. Dg-Dock7m+/+Lepr(db) mice (db/m) on the C57BLKS/J background were purchased from Clea Japan Co. Ltd (Tokyo, Japan). Ca_{2.2}^{−/−} mice were backcrossed with db/m mice on C57BLKS/J more than six times. We prepared six groups as follows: db/+; Ca_{2.2}^{−/−} mice, db/+; Ca_{2.2}^{+/−} mice, db/+; Ca_{2.2}^{+/+} mice, db/db Ca_{2.2}^{−/−} mice, and db/db Ca_{2.2}^{+/−} mice. Male diabetic db/db mice and their non-diabetic db/+ mice (control) were used in this study. Blood pressure was measured by the tail-cuff method (MK-2000ST; Muromachi Kikai, Tokyo, Japan) every 4 weeks32. Urine samples were collected using metabolic cages every 2 weeks for measurement of creatinine and albumin28. Thereafter, mice were sacrificed at 16 weeks of age.

Nitrrendipine (15 mg/kg/day; a gift from Tanabe Mitsubishi pharmaceutical company), cilnidipine (15 mg/kg/day; a gift from Mochida pharmaceutical company) or vehicle were mixed with powdered food at 150–187.5 μg/g. Plasma insulin levels were measured by enzyme immunoassay (Ultra-sensitive PLUS mouse insulin kit, Morinaga, Yokohama, Japan)34. For GTTs, after 16-h fasting, 2 or 1 g/kg glucose, respectively34. We measured catecholamines in 24-h urine by adding 1 mL 6N HCl per 100 ml of urine. Urinary albumin was measured with murine albumin enzyme-linked immunosorbent assay (Exocell, Philadelphia, PA)32. HbA1c values were determined as described previously33.

Renal histology, immunohistochemistry, and electron microscopy. Histologic and immunohistochemical examinations were performed as described previously32. Immunofluorescence analyses for nephrin and podocin were performed as described previously32. Immunohistochemical studies for phospho-ERK and Mac2 (also known as lectin galactoside-binding soluble 3, LGALS3) were performed as described19,32. For the double immunohistochemical study for Wils’s tumor factor-1 (WT1) and Ca_{2.2} kidney sections were fixed with Brasis’s fixative. Sections were boiled for 10 min for antigen retrieval. After blocking, sections were incubated with both goat anti-WT-1 antibody (Santa Cruz Biotechnology, Santa Cruz, CA) and rabbit anti-Ca_{2.2} antibody (Alomone Labs, Jerusalem, Israel) for 1 h at room temperature. Then, sections were incubated with alkaline phosphatase-conjugated anti-goat IgG and peroxidase-conjugated anti-rabbit IgG (Jackson Immunoresearch,
West Grove, PA) for 1 h. Electron microscopy analysis was performed as described previously. The GMB thickness was measured with the Image J software (Ver 1.45; National Institutes of Health, Bethesda, MD).

**Real-time RT-PCR analysis.** Total RNA was extracted using AllPrep DNA/RNA/Protein Mini Kit (Qiagen, Germantown, MD) from glomeruli that were isolated by the graded sieving method. Quantitative real-time PCR was performed using Premix Ex Taq (Takara Bio, Otsu, Japan) on the StepOnePlus system (Applied Biosystems, Foster City, CA) as described previously. Glomerular expression of TGFβ1, Ctgf, Col3a1, Cacna1b, Cacna1c, Cacna1g, Fn1 and Col1a1 mRNA was evaluated. Some of primers and probe sets were described elsewhere and as follows: Cacna1b forward primer, 5′-gagaccaacgggctgcac-3′; Cacna1b reverse primer, 5′-ctgagctgtccctcgc-3′; Cacna1b probe, 5′-FAM-cagagactcaccagggc-TAMRA-3′; Cacna1c forward primer, 5′-agacgtctgtaacaactga-3′; Cacna1c reverse primer, 5′-ggagatgctgagggcag-3′; Cacna1c probe, 5′-FAM-ttccctcgatctacccgaca-TAMRA-3′; Cacna1g forward primer, 5′-ccgagagacgggtgctggtgat-3′; Cacna1g reverse primer, 5′-gtgctgctgctggttggtggtg-3′; Cacna1g probe, 5′-FAM-ccaaacggctgcttgctc-t-ac-TAMRA-3′. Expression of each mRNA was normalized with GAPDH mRNA (TaqMan roden GAPDH control reagents; Applied Biosystems).

**Cell culture.** Conditionally immortalized human podocytes were cultured as described previously. Differentiated podocytes were serum-starved for 24 h and then pretreated with 100 nM α-conotoxin (Peptide Institute, Osaka, Japan) or 10 μM nitrendipine at 1 h before the stimulation of recombinant human TGF-β1 (R&D Systems, Minneapolis, MN). Cells were harvested after 24 h, and the expression level of nephrin was assayed by real-time RT-PCR analysis (n = 5–12).

**Calcium imaging.** Calcium imaging was performed as described previously with some modification. Human podocyte cells were plated onto poly-L-lysine-coated glass coverslips and subjected to measurement 3–16 h after plating on the coverslips. The cells on coverslips were loaded with fura-2 in RPMI 1640 containing 1 mM fura-2-acetoxymethyl ester (fura-2-AM; Dojindo Laboratories, Kumamoto, Japan), 10% fetal bovine serum (Sigma), 10 μg/mL insulin, 5.5 μg/mL transferrin, 5 ng/mL selenium (Sigma), 30 units/mL penicillin, and 30 μg/mL streptomycin at 37°C for 30 min. The coverslips were then plated in a perfusion chamber mounted on the stage of the microscope. The fura-2 fluorescence images of the cells were recorded in HEPES-buffered saline (HBS, 2 mM Ca^2+) (in mM): 107 NaCl, 6 KCl, 1.2 MgSO4, 2 CaCl2, 1.2 KH2PO4, 11.5 glucose, and 20 HEPES (pH 7.4 adjusted with NaOH). Four minutes after image acquisition, the cells were stimulated with 107 mM K+ solution (in mM): 107 KCl, 6 NaCl, 1.2 MgSO4, 2 CaCl2, 1.2 KH2PO4, 11.5 glucose, and 20 HEPES (pH 7.4 adjusted with NaOH). All the reagents dissolved in water or dimethylsulfoxide were diluted to their final concentrations and applied to the cells by perfusion. Fluorescence images of the cells were recorded and analyzed with a video image analysis system (AQUACOSMOS; Hamamatsu Photonics, Shizuoka, Japan). The ratio of the fluorescence intensity at 340 nm to the intensity at 380 nm was calculated to evaluate the change in intracellular calcium levels.

**Statistical analysis.** Data are expressed as the mean ± SEM. Statistical analysis was performed using one-way ANOVA. P < 0.05 was considered statistically significant.
