The Ubiquitin Ligase CHIP Integrates Proteostasis and Aging by Regulation of Insulin Receptor Turnover

Graphical Abstract

Highlights

- The ubiquitin ligase CHIP triggers insulin receptor turnover
- Insulin receptor level is linked to insulin and IGF1 signaling and longevity
- Engagement of CHIP in protein quality control limits insulin receptor degradation
- Proteotoxic stress aggravates insulin receptor stability, drives aging, and shortens lifespan

SUMMARY

Aging is attended by a progressive decline in protein homeostasis (proteostasis), aggravating the risk for protein aggregation diseases. To understand the coordination between proteome imbalance and longevity, we addressed the mechanistic role of the quality-control ubiquitin ligase CHIP, which is a key regulator of proteostasis. We observed that CHIP deficiency leads to increased levels of the insulin receptor (INSR) and reduced lifespan of worms and flies. The membrane-bound INSR regulates the insulin and IGF1 signaling (IIS) pathway and thereby defines metabolism and aging. INSR is a direct target of CHIP, which triggers receptor monoubiquitylation and endocytic-lysosomal turnover to promote longevity. However, upon proteotoxic stress conditions and during aging, CHIP is recruited toward disposal of misfolded proteins, reducing its capacity to degrade the INSR. Our study indicates a competitive relationship between proteostasis and longevity regulation through CHIP-assisted proteolysis, providing a mechanistic concept for understanding the impact of proteome imbalance on aging.

INTRODUCTION

Proteostasis represents the functional balance of the proteome, which is permanently challenged by environmental stress and alterations in physiology. A decline in proteostasis leads to progressive aggregation of misfolded proteins, overwhelming the cellular protein quality control (PQC) networks. The maintenance of PQC mechanisms provided by molecular chaperones and proteolytic pathways is not only a long-term challenge for individual cells but also for the entire organism, given that damaged proteins dramatically accumulate with progressive aging (López-Otín et al., 2013).

The quality-control E3 ubiquitin ligase CHIP acts along with molecular chaperones and degradation machineries to keep the cellular balance between protein folding and degradation (Arndt et al., 2007; Connell et al., 2001; Cyr et al., 2002; Murata et al., 2003). CHIP provokes the ubiquitylation of damaged proteins consigned by chaperone partners to induce disposal through endocytic-lysosomal pathways (Okiyoneda et al., 2010; Slotman et al., 2012), proteosomal degradation (Connell et al., 2001; Cyr et al., 2002; Murata et al., 2003), and autophagy (Arndt et al., 2010). In agreement with its role in protein quality control, CHIP prevents an age-related pathologic accumulation of protein aggregates (Connell et al., 2001; Petrucelli et al., 2004). Surprisingly, however, CHIP−/− deletion mice exhibit normal embryonic development and unaffected turnover of many known CHIP substrates, suggesting functional redundancy among quality-control ubiquitin ligases (Min et al., 2008; Morishima et al., 2008). On the other hand, CHIP deficiency accelerates aging (Min et al., 2008), which points to the existence of at least one critical CHIP-specific substrate that controls longevity. However, the mechanistic link between proteostasis decline and aging has remained unexplained so far.

Insulin and insulin-like growth factor 1 (IGF1) signaling (IIS) represents an evolutionarily conserved pathway that senses nutrient supply and determines longevity in multicellular organisms (Barbieri et al., 2003). IIS defines various cellular processes, including innate immunity and stress response. Reduced insulin signaling extends lifespan and improves proteotoxic stress resistance via the activation of multiple transcription factors (Cohen et al., 2010; Hesp et al., 2015; Kenyon, 2010; Kevei and Hoppe 2014). DAF-2 has been identified as a membrane bound receptor regulating the IIS pathway in Caenorhabditis elegans. Mechanistically, downregulation of DAF-2 function activates the FOXO transcription factor DAF-16, causing dramatic lifespan extension (Kenyon et al., 1993). Besides extensive genetic analyses of the IIS pathway, however, the impact of DAF-2 protein level regulation on aging has not been addressed.

Here, we reveal an important function of CHIP-mediated proteolysis in IIS. We identify a degradation pathway that controls the level of active DAF-2/INSR in C. elegans, Drosophila...
Figure 1. CHIP Modulates Lifespan via Increased Insulin Signaling

(A) C. elegans chn-1 mutants (by155 and tm2692) exhibit short lifespans.

(B) Body size of chn-1 deficient worms is reduced, compared to wild-type worms (mean values ± SEM were obtained by measuring at least n = 20 worms). ***p < 0.001.

(C) Deletion of chn-1 shortens lifespan of eat-2(ad465) worms.

(D and E) DAF-16::GFP overexpression extends the lifespan of chn-1(by155) and chn-1(tm2692) worms.

(F) Depletion of daf-16 by RNAi shortens the lifespan of chn-1(by155) worms.

(legend continued on next page)
melanogaster, and human cells. The key regulator of this conserved mechanism is the ubiquitin ligase CHIP, which fine-tunes IIS via monoubiquitylation and subsequent endocyticlysosomal degradation of the insulin receptor. Upon proteotoxic stress and during aging, however, CHIP is preferentially shuttled towards quality-control pathways for degradation of damaged proteins, causing a stabilization of the INSR. Accordingly, proteotoxic accumulation of damaged proteins or aberrant CHIP function attenuates INSR degradation and affects metabolism and longevity through increased IIS. In conclusion, our results demonstrate a competition between proteostasis and lifespan regulation through CHIP-assisted proteolysis, providing an evolutionarily conserved concept for understanding the impact of proteome imbalance on aging.

RESULTS

Lack of the E3 Ligase CHIP Increases IIS Activity

To obtain insight into the physiological function of CHIP, we examined its role in aging, using C. elegans as a model organism. Interestingly, the loss-of-function alleles chn-1(by155) and chn-1(tm2692), both lacking the single CHIP worm ortholog CHN-1, showed reduced lifespan (Figures 1A and S1A; Table S1). The short lifespan phenotype of both deletion mutants was also recapitulated by RNAi depletion of chn-1 (Figure S1B; Table S1). chn-1(by155) worms exhibited reduced body size, which often reflects limited nutrient uptake (Figure 1B). Therefore, we investigated the effect of chn-1 depletion in context of the well-established longevity pathway triggered by dietary restriction (DR). DR can be reproduced genetically by using eat-2(ad465) mutants, which exhibit reduced pharyngeal pumping rates, causing lower food intake, smaller body size, and extended lifespan (Lakowski and Hekimi, 1998). However, deletion of chn-1 only partially shortened the lifespan of eat-2(ad465) mutant worms, suggesting that CHN-1 acts parallel to DR in a different longevity pathway (Figure 1C; Table S1).

IIS is well known to regulate both lifespan and metabolism in C. elegans (Perez and Van Gilst, 2008). Hence, the phenotypes we observed in the chn-1 deletion mutants could also be linked to this conserved signaling pathway (Kimura et al., 1997). Reduced activity of the DAF-2/INSR mobilizes the downstream FOXO transcription factor DAF-16, resulting in enhanced metabolism and extended lifespan of nematodes (Lin et al., 2001; Ogg et al., 1997). Nuclear localization of DAF-16 can be triggered by its overexpression to support transcriptional activity and longevity (Henderson and Johnson, 2001). In fact, transgenically expressed DAF-16::GFP was able to suppress both chn-1(by155) and chn-1(tm2692) deletion mutants and extended lifespan (Figures 1D and 1E; Table S1). Conversely, short lifespan caused by RNAi-mediated downregulation of daf-16 was not further reduced by chn-1 deletion. The combined depletion of both genes rather resulted in almost identical lifespan curves, suggesting an epistatic relationship (Figure 1F; Table S1).

In light of this genetic interaction, we further monitored DAF-16 nuclear localization as visual readout to test whether insulin signaling is increased in the absence of chn-1. In fact, localization of DAF-16::GFP into the nucleus was delayed in the chn-1(by155) deletion mutant (Figures 1G and S1C; Table S2), whereas it was enhanced by transgenic overexpression of chn-1::FLAG (Figures 1G, S1C, and S2A; Table S2). We wondered whether the reduced lifespan and DAF-16 mobility of chn-1 deletion worms might reflect reduced transcriptional activity of DAF-16. Recent studies identified several target genes of DAF-16 important for lifespan regulation (Lee et al., 2003). Following mRNA expression levels by real-time PCR, we identified reduced amounts of sod-3 and sip-1 mRNAs in worms lacking chn-1, similar to daf-16 loss-of-function, suggesting that CHN-1 is important for efficient activation of DAF-16 (Figure 1H).

Given the evolutionarily conserved function of insulin signaling (Barbieri et al., 2003), we wondered whether CHIP depletion provides similar short-lived phenotypes in D. melanogaster. In fact, RNAi-mediated downregulation of Drosophila CHIP (dCHIP) strongly reduced the lifespan of flies (Figure 1I; Table S1). Whereas the reduction of CHN-1 and dCHIP levels diminished longevity, overexpression did not enhance lifespan of worms and was even toxic in flies (Figures S2A–S2D; Table S1). Overexpression of the chaperone-associated ubiquitin ligase might cause an excessive routing of chaperone clients onto degradation pathways and might lead to non-physiological changes of the chaperone network given the HSF-1 regulating activity of CHIP (Dai et al., 2003; Qian et al., 2006).

Lifespan regulation critically depends on IIS signaling, which is activated upon ligand binding to the INSR at the plasma membrane and involves a cascade of intracellular phosphorylation events (van der Horst and Burginger, 2007). Given the impact of CHIP depletion on lifespan regulation and genetic correlation with IIS, we wondered whether any of the IIS downstream targets are regulated by CHIP-mediated degradation. In fact, depletion of CHIP did not influence the protein level of PDK1, AKT, or mTOR; also, the level of the chaperone Hsp90 remained unchanged in human embryonic kidney (HEK293) cells (Figure S2E). However, it increased AKT kinase phosphorylation in flies (S505, p-AKT) and human cells (S473, p-AKT) (Figures 1J and 1K), providing further evidence for increased insulin signaling upon
CHIP Activity Correlates with DAF-2/INSR Protein Level

Given our genetic epistasis data placing CHN-1 function upstream of DAF-2, we performed western blot analysis to monitor the DAF-2 protein level in vivo (Figure S2F). Intriguingly, DAF-2 abundance increased specifically later in life and was significantly enhanced in chn-1(by155) mutants especially at day 10 of adulthood (Figures 2A and 2B). This increase in worms lacking CHN-1 (Figure 2D), the stabilization of DAF-2 suggests a substrate-specific role of CHN-1 in IIS regulation rather than a general defect in ubiquitin-dependent protein degradation. In flies, the observed induction of AKT kinase phosphorylation upon loss of dCHIP was also accompanied by an increase of the dINSR level (Figures 1J and 2E). In agreement with increased insulin signaling activity, the stabilized receptor did not accumulate in detergent-insoluble aggregates (Figure 2F). Finally, depletion of human CHIP in HEK293 cells resulted in a significant increase in the total amount of ubiquitylated proteins in wild-type and chn-1(by155) mutant worms at days 1 and 10 of adulthood. Since there was no increase of ubiquitylated proteins detected in worm lysates lacking CHN-1 (Figure 2D), the stabilization of DAF-2 suggests a substrate-specific role of CHN-1 in IIS regulation rather than a general defect in ubiquitin-dependent protein degradation. Notably, proteasomal inhibition by MG132 did not affect INSR stability, thus excluding a critical contribution of autophagy to INSR degradation. In contrast to the role of CHN-1/CHIP, DAF-2 was not modified by the related ubiquitin ligases UFD-2 (Hoppe et al., 2004) or WWP-1, a HECT domain protein implicated in control of DR-dependent longevity (Figures 3D and S3B–S3D) (Carrano et al., 2009).

Different lysine (K) residues of ubiquitin are used for isopeptide bond formation between single ubiquitin molecules to form poly-ubiquitin chains with distinct linkages (Komander and Rape, 2012). Regardless of the use of wild-type (Ub) or a mutant form of ubiquitin without lysines (UbK0), we obtained a similar pattern of ubiquitylation on DAF-2 or the INSR in our defined in vitro studies, indicating that CHN-1/CHIP mediates multiple monoubiquitylation of the INSR rather than polyubiquitylation (Figures 3F and 3G). These experiments suggest a conserved role of CHIP in monoubiquitylation of the INSR in worms, flies, and human cells. The lysine residues that are ubiquitylated were identified by mass spectrometric analyses of modified DAF-2/INSR obtained from independent in vitro experiments. K1047 was preferentially used for INSR ubiquitylation in vitro and clusters with the additional conserved conjugation site K1057 (Figure S3E). In support of our findings, recent proteomic studies also identified K1047 as a major residue targeted for receptor ubiquitylation in human cells (Kim et al., 2011). In contrast to the INSR, CHIP is not able to ubiquitylate the insulin-like growth factor receptor 1 (IGF1R) (Figure S3I). Accordingly, depletion of CHIP did not stabilize IGF1R (Figure S3I). Together, these findings highlight the substrate-specific role of CHIP in INSR degradation both in vitro and in vivo.

Ubiquitylation Provokes Endocytic-Lysosomal Turnover of the INSR

Notably, proteasomal inhibition by MG132 did not affect INSR stability in HEK293 cells (Figure 4A). In contrast, the amount of INSR increased upon treatment of human cells with the lysosomal inhibitors bafilomycin A1 (BafA1) and chloroquine, or a dynamin inhibitor that blocks endocytosis (Figure 4A). Moreover, dynamin inhibition reversed the reduced INSR level boosted by CHIP overexpression (Figure 4B). These findings would be consistent with an endocytic-lysosomal or autophagic degradation pathway for INSR. To distinguish between these possibilities, we depleted the essential autophagy factor ATG7 from human HEK293 cells by siRNA and monitored INSR level (Komatsu et al., 2005). Efficient depletion of ATG7 significantly inhibited autophagy, as evident from p62 accumulation and reduced levels of lipidated LC3 (LC3-II) (Figure 4C). Yet, ATG7 depletion did not affect INSR stability, thus excluding a critical contribution of autophagy to INSR degradation. Importantly, the CHIP-targeted lysine K1047 of the INSR is crucial for receptor degradation in human cells given that the conservative K1047R amino acid substitution stabilized the INSR to the deletion of the entire domain (ΔU-box) (Figures 3D, S3B, and S3C) (Rosser et al., 2007). The amino-terminal tetratricopeptide repeat (TPR) domain of CHIP mediates interaction with Hsp70 and Hsp90, and is required for the intrinsic ability of CHIP to recognize substrate proteins (Rosser et al., 2007). Mutation of the TPR domain also inhibited receptor ubiquitylation, revealing that the domain contributes to the direct recognition of INSR by CHIP in the chaperone-free reaction (Figures S3C and S3D). In contrast to the role of CHN-1/CHIP, DAF-2 was not modified by the related ubiquitin ligases UFD-2 (Hoppe et al., 2004) or WWP-1, a HECT domain protein implicated in control of DR-dependent longevity (Figures 3D and S3B–S3D) (Carrano et al., 2009).

CHIP Binds and Monoubiquitylates the INSR

Regarding the correlation between CHN-1 and DAF-2 protein levels, we wondered whether the two proteins are directly associated. Indeed, we found that FLAG-tagged CHN-1 binds DAF-2 in immunoprecipitation assays by using lysates of transgenic worms expressing CHN-1::FLAG (Figures 3A, 3B, and S3A). Intriguingly, the interaction was most obvious at day 10 of adulthood, which correlates with the timing of DAF-2 protein level increase in worms lacking CHN-1 (Figures 2A and 2B). This interaction is evolutionarily conserved given that we also detected binding between the INSR and CHIP in human cell lysates (Figure 3C).

Regarding the direct interaction, we tested whether the INSR is a target for CHIP ligase activity and performed in vitro ubiquitylation assays with recombinantly expressed proteins. Indeed, we detected efficient ubiquitylation of DAF-2, dINSR, or INSR either by CHN-1, dCHIP, or human CHIP, respectively (Figures 3D–3G). This reaction was completely blocked by a H218Q point mutation within the conserved U-box domain of CHN-1, essential for E3 ligase catalytic activity (U-box), or complete deletion of the entire domain (ΔU-box) (Figures 3D, S3B, and S3C) (Rosser et al., 2007). The amino-terminal tetratricopeptide repeat (TPR) domain of CHIP mediates interaction with Hsp70 and Hsp90, and is required for the intrinsic ability of CHIP to recognize substrate proteins (Rosser et al., 2007). Mutation of the TPR domain also inhibited receptor ubiquitylation, revealing that the domain contributes to the direct recognition of INSR by CHIP in the chaperone-free reaction (Figures S3C and S3D). In contrast to the role of CHN-1/CHIP, DAF-2 was not modified by the related ubiquitin ligases UFD-2 (Hoppe et al., 2004) or WWP-1, a HECT domain protein implicated in control of DR-dependent longevity (Figures 3D and S3B–S3D) (Carrano et al., 2009).

Different lysine (K) residues of ubiquitin are used for isopeptide bond formation between single ubiquitin molecules to form poly-ubiquitin chains with distinct linkages (Komander and Rape, 2012). Regardless of the use of wild-type (Ub) or a mutant form of ubiquitin without lysines (UbK0), we obtained a similar pattern of ubiquitylation on DAF-2 or the INSR in our defined in vitro studies, indicating that CHN-1/CHIP mediates multiple monoubiquitylation of the INSR rather than polyubiquitylation (Figures 3F and 3G). These experiments suggest a conserved role of CHIP in monoubiquitylation of the INSR in worms, flies, and human cells. The lysine residues that are ubiquitylated were identified by mass spectrometric analyses of modified DAF-2/INSR obtained from independent in vitro experiments. K1047 was preferentially used for INSR ubiquitylation in vitro and clusters with the additional conserved conjugation site K1057 (Figure S3E). In support of our findings, recent proteomic studies also identified K1047 as a major residue targeted for receptor ubiquitylation in human cells (Kim et al., 2011). In contrast to the INSR, CHIP is not able to ubiquitylate the insulin-like growth factor receptor 1 (IGF1R) (Figure S3I). Accordingly, depletion of CHIP did not stabilize IGF1R (Figure S3I). Together, these findings highlight the substrate-specific role of CHIP in INSR degradation both in vitro and in vivo.

Ubiquitylation Provokes Endocytic-Lysosomal Turnover of the INSR

Notably, proteasomal inhibition by MG132 did not affect INSR stability in HEK293 cells (Figure 4A). In contrast, the amount of INSR increased upon treatment of human cells with the lysosomal inhibitors bafilomycin A1 (BafA1) and chloroquine, or a dynamin inhibitor that blocks endocytosis (Figure 4A). Moreover, dynamin inhibition reversed the reduced INSR level boosted by CHIP overexpression (Figure 4B). These findings would be consistent with an endocytic-lysosomal or autophagic degradation pathway for INSR. To distinguish between these possibilities, we depleted the essential autophagy factor ATG7 from human HEK293 cells by siRNA and monitored INSR level (Komatsu et al., 2005). Efficient depletion of ATG7 significantly inhibited autophagy, as evident from p62 accumulation and reduced levels of lipidated LC3 (LC3-II) (Figure 4C). Yet, ATG7 depletion did not affect INSR stability, thus excluding a critical contribution of autophagy to INSR degradation. Importantly, the CHIP-targeted lysine K1047 of the INSR is crucial for receptor degradation in human cells given that the conservative K1047R amino acid substitution stabilized the INSR to the depletion of CHIP (Su et al., 2011). Collectively, these results suggest that CHIP provides a conserved role in the regulation of IIS activity.
same extent as inhibition of lysosomal degradation by chloroquine treatment (Figures 4D, 4E, and S3E). Taken together, our data reveal an endocytic and lysosomal pathway for INSR turnover initiated by CHIP-dependent monoubiquitylation.

**CHIP-Dependent Ubiquitylation of DAF-2 Is Linked to Longevity**

We further assessed the physiological relevance of the ubiquitin ligase activity by expressing wild-type and mutated variants of DAF-2.

Figure 2. CHIP Regulates DAF-2/INSR Protein Level

(A, B) chn-1(by155) shows increased levels of DAF-2 protein, analyzed by immunoblotting of worm lysates of indicated age (day 0; L4 worms) (mean values were obtained in n = 6 independent experiments).

(C) Lack of UFD-2 does not stabilize DAF-2.

(D) chn-1(by155) mutation does not increase the global level of ubiquitylated proteins in young or aged adult worms.

(E) Ubiquitous depletion of dCHIP increases levels of dINSR (detected in whole fly extracts) (mean values were obtained in n = 5 independent experiments).

(F) dINSR stabilized upon dCHIP depletion does not accumulate in detergent-insoluble aggregates. Fly heads were lysed in SDS-containing buffer and the resultant extract was separated in an SDS-soluble and -insoluble fraction by centrifugation at 100,000 × g.

(G) Depletion of CHIP in human HEK293 cells causes increased levels of INSR as determined by western blot, whereas mRNA levels remain unchanged (mean values were obtained in n = 5 independent experiments).

(H) Overexpression of CHIP results in decreased level of INSR in HEK293 cells (mean values were obtained in n = 5 independent experiments).

(B, E, G, and H) Data are means ± SEM. *p < 0.05, **p < 0.01.

See also Figure S2.
In the *chn-1*(by155) deletion strain. Unlike wild-type CHN-1, the catalytically inactive CHN-1(U-box) mutant defective in DAF-2 ubiquitylation was not able to rescue the shortened lifespan phenotype of *chn-1*(by155) worms (Figures 5A, 5B, and S3A). This result supports the idea that CHN-1-dependent ubiquitylation of DAF-2 is tightly linked to regulation of longevity. To further clarify whether the level of DAF-2 strictly correlates with lifespan, we analyzed its protein amount in different *C. elegans daf-2* mutant alleles (Figure 5C) (Kimura et al., 1997; Malone and Thomas, 1994; Patel et al., 2008; Scott et al., 2002). The hypomorphic *daf-2(e1368)* mutant promotes longevity and is able to extend the short lifespan of *chn-1*-deficient worms.

Figure 3. CHIP Binds and Monoubiquitylates DAF-2/INSR
(A and B) CHN-1 interacts with DAF-2. Receptor complexes were isolated by immunoprecipitation from wild-type worms expressing CHN-1::FLAG (1st or 10th day of adulthood).
(C) CHIP interacts with INSR in human cells. After transient transfection of HEK293 cells with a FLAG::CHIP expressing plasmid, INSR complexes were isolated by immunoprecipitation.
(D and E) Ubiquitylation reactions of DAF-2 and dINSR were carried out as indicated using CHN-1(WT), CHN-1(U-box), CHIP, dCHIP, WWP-1, and UFD-2 as ubiquitin ligases.
(F and G) DAF-2/INSR undergoes monoubiquitylation. In vitro ubiquitylation assays were carried out as indicated using wild-type ubiquitin or a lysine-lacking variant (Ub\(^{K0}\)). Samples from experiments analyzing mono vs. polyubiquitylation (G) were run on separate gels and are presented here separated by a dashed line.
(H) CHIP does not ubiquitylate IGF1R. Ubiquitylation reactions of IGF1R and INSR were carried out as indicated using CHIP as ubiquitin ligase. Samples from experiments analyzing IGF1R and INSR ubiquitylation were run on separate gels and are presented here separated by a dashed line.
(I) Depletion of CHIP in human HEK293 cells does not affect protein levels of IGF1R. Data are means ± SEM obtained in n = 4 independent experiments. See also Figure S3.
This genetic suppression further supports the idea that the shortened lifespan of \textit{chn-1} depletion is caused by DAF-2 stabilization (Figures 2A and 2B). In contrast to \textit{e979} and \textit{e1391} temperature-sensitive mutant proteins, the DAF-2\textit{e1368} protein amount is elevated at day 5 of adulthood (Figure 5C). When combined with \textit{chn-1}(by155), DAF-2\textit{e1368} lifespan was slightly reduced, which is in line with further increase of DAF-2\textit{e1368} level in the \textit{chn-1}(by155) mutant background (Figures 5D and 5E). Contrary to all other long-lived loss-of-function alleles, the \textit{daf-2}(\textit{gk390525}) allele (Thompson et al., 2013; Bulger et al., 2017) displayed increased DAF-2 level already at day 1 of adulthood and shortened lifespan (Figures 5C and 5F). Intriguingly, \textit{daf-2}(\textit{gk390525}) harbors a single point mutation in K1614E, one of the lysine residues in DAF-2 targeted for CHN-1-dependent ubiquitylation (Figures 3D and S3E). Thus, defective ubiquitylation seems to result in an elevated DAF-2\textit{gk390525} protein level and premature aging. Indeed, the reduced lifespan of \textit{daf-2}(\textit{gk390525}) worms can be extended again by RNAi-mediated depletion of \textit{daf-2} (Figure 5G). Moreover, the DAF-2\textit{gk390525} level was not further increased and lifespan of \textit{daf-2}(\textit{gk390525}) is not more diminished when combined with the \textit{chn-1}(by155) mutation, again highlighting the substrate-specific role of CHN-1 in DAF-2 ubiquitylation and turnover (Figures 5H, 5I, and S4A). These observations further indicate that CHN-1-mediated ubiquitylation regulates DAF-2 stability, insulin signaling, and longevity.
Figure 5. CHN-1 Ligase Activity Regulates DAF-2 Degradation and Longevity
(A and B) CHN-1::FLAG expression rescues the short lifespan of chn-1(by155) mutant worms; catalytic inactive CHN-1(U-box)::FLAG does not.
(C) DAF-2 protein level increases during aging in analyzed daf-2 mutant alleles. Importantly, daf-2(gk390525) allele displays increased DAF-2 level already at day 1 of adulthood.
(D) Short lifespan of chn-1(by155) is suppressed by daf-2(e1368) loss-of-function mutant.
Proteolytic Regulation of IIS Is Diminished by Proteotoxic Stress

To address the physiological relevance of CHN-1/CHIP-dependent INSR degradation, CHN-1 was downregulated either during larval development of worms or from day 1 of adulthood onward. It turned out that *chn-1* is most important in adult life because its depletion specifically shortened life expectancy when applied post-developationally (Figures S5A and S5B). *chn-1* mutants are sensitive to heat stress, which might be linked to the age-related decline in proteostasis known to cause high abundance of misfolded proteins (Figure S5C) (Murata et al., 2003; Walther et al., 2015). In contrast to molecular chaperones, CHN-1 levels remained unchanged during aging and were not upregulated in response to different proteotoxic conditions (Figures 2A and 2D). A decline in proteostasis would thus redirect CHN-1 activity toward degradation of misfolded proteins and limit monoubiquitination of DAF-2. Indeed, worms shifted to high temperature at the beginning of adulthood (D1) showed elevated levels of DAF-2 protein similar to those of *chn-1* lacking mutants grown at normal conditions (Figures 2A, 6A, and 6B). In line with a central role in proteostasis, depletion of CHN-1/dCHIP in worms and flies caused high sensitivity to oxidative stress induced by paraquat treatment (Figures 6C and 6D). Moreover, in flies and human cells we also detected elevated level of the INSR upon oxidative stress (Figures 6E and 6F). This increase most likely reflects reduced receptor turnover caused by limited disposability of CHIP under proteotoxic stress. In support of this hypothesis, INSR levels could be restored in parapar-treated human cells by overexpression of CHIP (Figure 6F). Thus, ubiquitin ligase activity of CHIP seems to be limited under proteotoxic stress conditions. In addition, we also tested the impact of canavanine on dINSR stability in flies. Incorporation of this non-proteinogenic amino acid leads to aberrantly folded polypeptides and increased proteotoxicity (Dasuri et al., 2011; Rosenthal et al., 1987). Similar to increased oxidative stress, canavanine treatment strongly stabilized dINSR, providing additional support for the correlation between proteotoxic stress and INSR stability (Figure S5E).

The age-related collapse of proteostasis networks often induces aggregation of damaged and metabolizable proteins (Lopez-Otin et al., 2013; Walther et al., 2015). By transgenic expression of aggregation-prone fluorescently tagged polyglutamine (polyQ) expansions in intestinal and muscle cells (Morley et al., 2002; Mohri-Shiomi and Garsin, 2008), we found that acute depletion of *chn-1* by RNAi caused early-onset protein aggregation and cellular toxicity in *C. elegans* (Figures 6G and S5F). This observation is in line with recent findings (Kalai et al., 2011; Matsumura et al., 2013; Min et al., 2008; Rosser et al., 2007), reflecting an important role of CHN in maintenance of the cellular proteome. We next addressed the role of CHIP in protein aggregation by using human cells expressing an extended polyglutamine repeat sequence fused to GFP (polyQ103-GFP). PolyQ103-GFP formed large, intracellular inclusion bodies that efficiently recruited cytosolic CHIP (Figure 6H). The recruitment toward protein aggregates diminished the pool of CHIP throughout the cytosol, which did not affect the amount of IGF1R, but specifically led to a strong increase of INSR level (Figure 6I). The observed increase could be attributed to reduced INSR turnover by monitoring the mRNA to protein ratio (Figure S5G). Taken together, our findings illustrate that CHIP integrates proteolysis of damaged proteins, which accumulate under proteotoxic stress conditions or during aging, with regulation of INSR turnover and IIS activity (Figure 7).

**DISCUSSION**

This study uncovered a balanced crosstalk between proteostasis maintenance and longevity, which paves the way toward understanding how proteome instability contributes to aging. A central node of this conserved mechanism is the quality-control E3 ubiquitin ligase CHIP, which tightly cooperates with the molecular chaperones Hsp70 and Hsp90 in the degradation of damaged proteins (Arndt et al., 2007; Connell et al., 2001; Cyr et al., 2002; Murata et al., 2003; Petruccelli et al., 2004).

We demonstrate here that CHIP mediates ubiquitin-dependent degradation of the INSR and thereby modulates insulin signaling and longevity. CHIP ubiquitylated the INSR in vitro in the absence of its partner chaperones, pointing to a specific and direct recognition of the receptor, distinct from the reported role in chaperone-dependent processing of misfolded proteins (Zhang et al., 2005; Stankiewicz et al., 2010) (Figures 3D-3G). The substrate specificity of the observed interaction is further highlighted by the fact that CHIP does not ubiquitylate or induce the degradation of the closely related IGF1R (Figures 3H, 3I, and 6H). Moreover, INSR ubiquitylation could not be induced by other ubiquitin ligases such as WWP-1 or UFD-2, which cooperates with CHN-1/CHIP on muscle-specific degradation pathways. In agreement with a specific functional interplay, DAF-2/INSR was stabilized by CHN-1/CHIP depletion or by mutations of DAF-2/INSR ubiquitylation sites utilized by CHIP (Figures 2A, 2B, 2E, 2G, 4E, 5C, and S5E). In all cases, receptor stabilization significantly shortened lifespan, illustrating the close independence of CHIP-mediated INSR degradation and longevity regulation.

In contrast to the reduced lifespan caused by CHN-1 or dCHIP depletion, overexpression did not enhance longevity of worms and was even toxic in flies (Figures S2A-2D; Table S1). CHIP is known to modulate the proteotoxic stress response by activating the transcription factor HSF-1 (heat shock factor 1) and by reducing the level of Hsp70 after heat shock (Dai et al., 2003;...
Figure 6. Regulation of INSR Stability Competes with Degradation of Damaged Proteins

(A and B) Temperature-shifted (15°C to 25°C at day 1 of adulthood) wild-type worms show an age-related increase in DAF-2 protein level (mean values were obtained in n = 6 independent experiments).

(C) chn-1(by155) mutant worms are sensitive to oxidative stress. Young adult wild-type and chn-1(by155) mutant worms were treated with 5 mM paraquat, and their survival rates were measured for the indicated time (mean values were obtained in n = 4 independent experiments).

(D) dCHIP depleted flies show increased sensitivity to paraquat treatment, causing reduced lifespan. Control and RNAi depleted flies were treated with food containing 20 mM paraquat, and their survival rates were determined (n = 5 independent experiments).

(E) Paraquat treatment leads to a significant stabilization of dINSR as determined in adult head extracts (mean values were obtained in n = 3 independent experiments).

(F) Oxidative stress induced by paraquat causes stabilization of INSR in HEK293 cells, which is compensated by CHIP overexpression (mean values were obtained in n = 5 independent experiments).

(G) chn-1 deletion enhances the age-dependent aggregation of the polyQ protein Q44::YFP. Worms with diffuse or aggregated intestinal staining of Q44::YFP were scored and plotted against the age of the worms (mean values were obtained in n = 6 independent experiments).

(H) CHIP is recruited to inclusion bodies formed by aggregation prone polyQ-103 in HeLa cells as detected by confocal microscopy. Scale bar represents 10 μm.

(I) Expression of aggregation prone polyQ-103 in HEK293 cells causes INSR but not IGF1R stabilization (mean values were determined in n = 5 independent experiments).

(B, C, E, F, H, and J) Data are means ± SEM. *p < 0.05, **p < 0.01, ***p < 0.001. See Table S1 for lifespan statistics. See also Figure S5.
UbLysosome

Figure 7. Model for the Reciprocal Regulation of Proteostasis and Longevity

The membrane bound DAF-2/INSR triggers IIS and thereby adjusts stress response and lifespan. Under normal conditions (unstressed), CHIP binds DAF-2/INSR to mediate monoubiquitylation and initiate the endocytic-lysosomal turnover of the receptor. Upon proteotoxic stress conditions, CHIP activity is recruited toward quality-control pathways for degradation of damaged proteins. Thus, proteome maintenance competes with ubiquitylation and degradation of the INSR, which in turn affects IIS, metabolism, and lifespan. Qian et al., 2006). Thus, the rather toxic effect of elevated CHIP level might be caused by non-physiological changes of the chaperone network with deleterious consequences (Yan et al., 2003; Stankowski et al., 2011). Accordingly, endogenous CHN-1 protein amounts also remained unchanged during aging or in response to proteotoxicity (Figures 2A and S5D). CHN-1-dependent DAF-2 turnover was also not affected by dietary interventions (Figure S5A). These observations suggest an intricately balanced regulation of CHN-1/CHIP activity to avoid excessive rerouting of chaperone substrates toward degradation. Irrespective of organismal changes, however, overexpression of CHIP directly affected INSR protein levels and compensated the stress-induced stabilization of the receptor in human cells (Figures 4B and 6F).

chn-1(by155) mutants were sensitive to heat stress, oxidative stress, and protein aggregation, similar to what we observed upon inactivation of CHIP (Figures 6C, 6D, 6G, S5C, and S5F). Moreover, these proteotoxic conditions also caused elevated DAF-2/INSR levels (Figures 6A, 6E, 6F, 6I, S5E, and S5G). Given these findings, it is intriguing to speculate that CHIP integrates proteolysis of damaged proteins with INSR degradation to control metabolism and longevity (Figure 7). Accumulation of damaged proteins upon proteotoxic conditions and during aging challenges the dynamic equilibrium of quality-control networks and shuttles CHIP into PQC pathways to degrade damaged proteins, causing stabilization of the functional INSR and consequently lifespan reduction (Figure 7). From the organismal perspective, the prioritization of proteome stability is highly beneficial and ensures reproduction early in life, but this is provided at the expense of aging. CHN-1 activity seems to be most important later in life (Figures 2A, 2B, 6A–6C, 6G, S5A, and S5B), suggesting that other recently identified quality-control ubiquitin ligases might help to maintain proteostasis during development (Fang et al., 2014; Heck et al., 2010).

Like C. elegans and Drosophila, CHIP-deficient mice develop normally but exhibit reduced lifespan associated with age-related pathophysiological defects (Min et al., 2008). With regard to the conserved regulation, it is intriguing that mutations in the orthologous human gene STUB1 are linked to accelerated aging (Heimdal et al., 2014). Given the importance of insulin signaling for metabolic regulation, it is also interesting that liver cells of CHIP-null mutant mice develop insulin resistance (Kim et al., 2016). Moreover, a single point mutation in K1095E, a lysine residue in the human INSR that we identified to be ubiquitylated, is also associated with severe insulin resistance of patients suffering from diabetes (Arden et al., 2014; O’Rahilly et al., 1991). These strong functional similarities suggest an evolutionarily conserved coordination of proteostasis and aging regulated by CHIP-assisted degradation. A detailed understanding of how INSR degradation is adjusted to metabolic insults might lead to efficient therapies for age-related diseases, including obesity and diabetes.

**STAR METHODS**

Detailed methods are provided in the online version of this paper and include the following:

- **KEY RESOURCES TABLE**
- **CONTACT FOR REAGENT AND RESOURCE SHARING**
- **EXPERIMENTAL MODEL AND SUBJECT DETAILS**
  - Caenorhabditis elegans Maintenance and Transgenic Lines
  - Drosophila melanogaster
  - Human Cells
- **METHOD DETAILS**
  - Lifespan Analysis
  - RNA Interference
  - C. elegans Body Length Measurements
  - C. elegans Body Bends Measurements
  - DAF-16:GFP Localization Assay
  - Microscopy
  - RNA Isolation and Real-Time PCR
  - Protein Extraction, Binding Assays, and Immunotechniques
  - Protein Expression and siRNA in Human Cells
  - In Vitro Ubiquitylation
  - Stress Assays
  - Statistical Analysis

**SUPPLEMENTAL INFORMATION**

Supplemental Information includes six figures and three tables and can be found with this article online at http://dx.doi.org/10.1016/j.cell.2017.04.003.

**AUTHOR CONTRIBUTIONS**

R.T., W.P., and E.K. designed, performed, and analyzed the experiments. R.T. and S.A. performed Drosophila and cell culture studies; W.P., E.K., M.E.A., and V.B., performed C. elegans studies. W.P. performed in vitro ubiquitylation assays, mass spectrometric analyses, and most final experiments for the revisions. T.H.

EXPERIMENTAL MODEL AND SUBJECT DETAILS

**Caenorhabditis elegans** Maintenance and Transgenic Lines

The following strains were used in this study: Bristol (N2) strain as wild-type (WT) strain, chn-1(by155)I, chn-1(tm2692)I, daf-18(md447)I, daf-16(mu86)I, daf-16(m26)I, ufd-2(tm1380)II, eat-2(ad465)II, daf-2(e1368)III, daf-2(m212)III, daf-2(m596)III, daf-2(m579)III, daf-2(sa193)III, daf-2(e979)III, daf-2(e1391)III, daf-2(m577)III, daf-2(ck390525)III, unc-119(ed4)III, zls356 [daf-16::daf-16::GFP], dgEx80[pAMS66 vha-6p::Q44::YFP+ rol-6(su1006)], mls133[unc-54p::Q40::YFP]. Unless otherwise stated mutant strains were at least six times outcrossed against the wild-type strain to provide isogenic conditions. Nematodes were grown at 20°C (unless otherwise stated) on nematode growth medium (NGM) agar plates seeded with *Escherichia coli* OP50 spread over the surface as a food source (Brenner, 1974). Transgenic animals expressing the *chn-1*::*flag* were constructed by PCR amplification (Table S3) of the wild-type genomic DNA (567 bp *chn-1* promoter and 2783 bp *chn-1* genomic DNA) and the *unc-54* 3’ UTR (877 bp) and cloned into the pBSK vector containing the *unc-119* marker for selection of transgenic worms. FLAG tag was fused to the N terminus of the gene by using the QuikChange Lightning Site-Directed Mutagenesis Kit (Agilent Technologies) (Table S3). Deletion of the U-box domain, mutation of the U-box (H218Q), or TPR (N9D, K13A, K73A) domain was introduced by QuikChange Lightning Site-Directed Mutagenesis Kit (Table S3). The constructs were particle bombardaged into *unc-119(ed4)III* mutants as described previously (Prajit et al., 2001). Microparticle bombardment of *C. elegans* *unc-119(ed4)* hermaphrodites was carried out using a BioRad Biolistic PDS-1000/HE with 1/4”gap distance, 9 mm macrocarrier to screen distance, 28 inches of Hg vacuum, and 1350 p.s.i. rupture disc. For each bombardment, 1 µl of 1–2 µg/µl plasmid DNA was coupled to 0.6 mg of 1.0–µm microcarrier gold beads, and bombarded onto a monolayer of ~10,000 *unc-119(ed4)* L4 and adult hermaphrodites (70-80 µl pellet) placed on 90-mm NGM plates. Worms were allowed to recover for 1 hr after bombardment and were then transferred onto ten 90-mm NGM plates seeded with OP50 E. coli and grown at 20°C. Transgenic animals expressing the *actin-1p::flag* were constructed by PCR amplification (Table S3) of the wild-type genomic DNA (567 bp *actin-1* promoter and 2783 bp *actin-1* genomic DNA) and the *unc-54* 3’ UTR (877 bp) and cloned into the pBSK vector containing the *unc-119* marker for selection of transgenic worms. FLAG tag was fused to the N terminus of the gene by using the QuikChange Lightning Site-Directed Mutagenesis Kit (Agilent Technologies) (Table S3). Deletion of the U-box domain, mutation of the U-box (H218Q), or TPR (N9D, K13A, K73A) domain was introduced by QuikChange Lightning Site-Directed Mutagenesis Kit (Table S3). The constructs were particle bombardaged into *unc-119(ed4)III* mutants as described previously (Prajit et al., 2001). Microparticle bombardment of *C. elegans* *unc-119(ed4)* hermaphrodites was carried out using a BioRad Biolistic PDS-1000/HE with 1/4”gap distance, 9 mm macrocarrier to screen distance, 28 inches of Hg vacuum, and 1350 p.s.i. rupture disc. For each bombardment, 1 µl of 1–2 µg/µl plasmid DNA was coupled to 0.6 mg of 1.0–µm microcarrier gold beads, and bombarded onto a monolayer of ~10,000 *unc-119(ed4)* L4 and adult hermaphrodites (70-80 µl pellet) placed on 90-mm NGM plates. Worms were allowed to recover for 1 hr after bombardment and were then transferred onto ten 90-mm NGM plates seeded with OP50 E. coli and grown at 20°C. Transgenic animals expressing the *actin-1p::flag* were constructed by PCR amplification (Table S3) of the wild-type genomic DNA (567 bp *actin-1* promoter and 2783 bp *actin-1* genomic DNA) and the *unc-54* 3’ UTR (877 bp) and cloned into the pBSK vector containing the *unc-119* marker for selection of transgenic worms. FLAG tag was fused to the N terminus of the gene by using the QuikChange Lightning Site-Directed Mutagenesis Kit (Agilent Technologies) (Table S3). Deletion of the U-box domain, mutation of the U-box (H218Q), or TPR (N9D, K13A, K73A) domain was introduced by QuikChange Lightning Site-Directed Mutagenesis Kit (Table S3). The constructs were particle bombardaged into *unc-119(ed4)III* mutants as described previously (Prajit et al., 2001). Microparticle bombardment of *C. elegans* *unc-119(ed4)* hermaphrodites was carried out using a BioRad Biolistic PDS-1000/HE with 1/4”gap distance, 9 mm macrocarrier to screen distance, 28 inches of Hg vacuum, and 1350 p.s.i. rupture disc. For each bombardment, 1 µl of 1–2 µg/µl plasmid DNA was coupled to 0.6 mg of 1.0–µm microcarrier gold beads, and bombarded onto a monolayer of ~10,000 *unc-119(ed4)* L4 and adult hermaphrodites (70-80 µl pellet) placed on 90-mm NGM plates. Worms were allowed to recover for 1 hr after bombardment and were then transferred onto ten 90-mm NGM plates seeded with OP50 E. coli and grown at 20°C. Because *unc-119* mutants cannot form dauers, they die in the absence of food (Maduro and Pilgrim, 1995), making it easy to identify the non-Unc rescued transformants 14 days after bombardment. From each plate containing animals rescued for the *unc-119* mutation, individual transformed animals were cloned and their F1 progeny scored for presence of *unc-119* mutants. Homozygous stable lines were identified by the complete absence of *unc-119* mutant progeny over several generations. Heterozygous lines were identified based on the presence of three distinct classes of progeny: heterozygous transformed animals, homozygous untransformed animals, and a third class of sterile or inviable animals. To ensure that each line was the result of an independent transformation event, we retained only one transformed line from each NGM plate. Transgenic strains generated in this study are as following: *unc-119(ed4)III*; *hhIs136[unc-119(+)],* *chn-1p::flag*; *unc-119(ed4)III*; *hhls145[unc-119(+)],* *chn-1p::flag*; *hhls136[unc-119(+)],* *chn-1p::flag*; *unc-119(ed4)III*.

**Drosophila melanogaster**

The following strains were used in this study: *w*1118 were used as wild-type flies, dCHIP-RNAi (VDRS stock number 10538), actin-GAL4 (#B8-3954, Bloomington stock center), UAS-dCHIP (kindly provided by Verena Arndt, University of Bonn), TIGS-2 (kindly provided by Scott Pletscher, University of Michigan). Flies were maintained on standard *Drosophila* Jazz-Mix instant food (Fisher Scientific) at 25°C and 65% humidity in a 12 hr light/12 hr dark incubator. For ubiquitous depletion RNAi flies were crossed to actin-GAL4 driver line. Control flies are of the genotype actin-GAL4/w1118. For overexpression of dCHIP in adult midguts UAS-dCHIP

flies were crossed to the TIGS-2 driver line. Expression of dCHIP was induced by placing flies of the same genetic background on RU486-containing (induced) or ethanol-containing (non-induced) food. For food preparation, a 25 mg/ml stock solution of RU486 (Mifepristone, Sigma) was made in 100% ethanol. Appropriate volumes of the 25 mg/ml RU486 stock solution were diluted with water and ethanol to a final ethanol concentration of 2% to avoid RU486 precipitation. 500 μl of the diluted solution with the desired concentration of RU486 was added onto the surface of standard fly food. The vials were then allowed to dry at room temperature for 24–36 hr depending on the ambient humidity. For paraquat or canavanine food the indicated concentration was solved in 1 ml water and applied onto the surface of standard fly food and further processed as mentioned above. Flies were flipped every other day.

**Human Cells**

HEK293 cells were cultured at 37°C under 5% CO2 in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine serum, L-glutamine, penicillin/streptomycin (PS), sodium pyruvate and non-essential amino acids (NEAA). HeLa cells were cultured at 37°C under 5% CO2 in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine serum and penicillin/streptomycin (PS).

**METHOD DETAILS**

**Lifespan Analysis**

In lifespan assays, first day of adulthood was defined as day 1. From day 0 on, synchronized worm populations (50 worms per plate for a total of 200 individuals per experiment) were transferred daily to fresh NGM plates seeded with OP50 *E. coli* until egg laying ceased. For RNAi based lifespan assays 50 synchronized L1 stage worms were fed with OP50 *E. coli* or with gene-specific RNAi expressing HT115 *E. coli* bacteria. Worms were transferred daily to fresh plates until egg laying ceased. Worms were examined every day for touch-provoked movement and pharyngeal pumping, until death. Animals that crawled off the plates or died owing to internal hatching of progeny or extruded organs were censored. For lifespan measurement in *D. melanogaster*, male flies were collected within 24 hr from eclosion and maintained at standard density (up to 30 flies per vial) on *Drosophila* Jazz-Mix instant food or in case of induced expression on either RU486-containing (induced) or ethanol-containing (non-induced) food. Dead flies were counted and food was changed every other day. For each genotype, at least 5 independent cohorts of flies raised at different times from at least 5 independent crosses were analyzed. Statistical data of individual lifespan experiments is presented in Table S1. The experiments were not randomized and the investigators were not blinded to allocation during experiments and outcome assessment. No statistical methods were used to predetermine sample size.

**RNA Interference**

RNAi in *C. elegans* was performed using the RNAi feeding method (Timmons and Fire, 1998). L1 or L4 larvae of wild-type worms were placed on HT115 *E. coli* bacteria expressing daf-2 or daf-16-specific double-stranded RNA (dsRNA). As wild-type control, bacteria transformed with the empty pPD129.36 vector were used as food source. For developmental or post-developmental silencing of chn-1 L1 larvae or day 1 adult worms were placed on chn-1 dsRNA expressing HT115. RNAi in flies was induced by binary UAS-GAL4 system (Brand and Perrimon, 1993). For ubiquitous depletion RNAi flies were crossed to actin-Gal4 driver line. Control flies are of the genotype actin-Gal4/W1118.

**C. elegans Body Length Measurements**

Worms were maintained at 20°C until the first day of adulthood. Relative body length of worms was measured by taking images of worms with a Leica M165FC stereomicroscope (10X eye piece, 0.75 - 6.0 zoom ratio) using 50 X magnification. Images were transformed to jpeg format and body length of worms was determined by drawing a line on the longitudinal axis of each worm in ImageJ 1.48v software. Relative values of body length was calculated by using the mean body length value of at least 20 single worms of each genotype and normalizing these values against WT worms’ mean body length.

**C. elegans Body Bends Measurements**

Body-bend assays were performed in a M9 buffer at room temperature. Individual day-1 adult worm was placed in 50 μl M9 buffer on a microscope slide and the number of left and rightward body bends in 30 s were counted, where one leftward and one rightward bend is equal to one stroke.

**DAF-16::GFP Localization Assay**

The synchronized DAF-16::GFP containing strains were maintained at 20°C. 100 day-1 old adult worms were transferred to small plates (35x10mm) seeded with OP50 and subjected to 35°C heat shock for indicated time in water bath and immediately visualized using Zeiss Axio Zoom.V16 microscope. Worms were classified into two categories based on the extent of DAF-16::GFP nuclear-cytoplasmic distribution.
Microscopy
Fluorescence and DIC images of worms were taken with an Axio Imager Z1 microscope mounted with AxioCam 503 mono camera (Carl Zeiss), and processed with the analysis software Zen 2012 SP1 (Carl Zeiss). HeLa cells were transfected with pCMV-tag2b-CHIP and pEGFP-PolyQ-25 or pEGFP-PolyQ-103 for 48 hr. Cells were then washed two times with PBS, followed by fixation in 4% paraformaldehyde for 15 min. After another washing step, cells were permeabilized for 10 min in PBS containing 0.2% Triton-100. Cells were blocked in 3% bovine serum albumin for 30 min and afterward washed 3 times in PBS. Primary antibody incubation was performed in 1:200 dilution in PBS for 1 hr. Alexa-labeled secondary antibodies (Invitrogen) were used in a 1:500 dilution for 1 hr. Cells were washed again for 3 times in PBS and afterward mounted in Mowiol. Images were acquired using a Zeiss Axiovert 510 microscope.

RNA Isolation and Real-Time PCR
Total RNA was isolated using TRIzol (Invitrogen) and QIAGEN RNeasy kit. Worms were washed off the plates using M9 buffer and 1 ml TRIzol, and silica beads (1 mm diameter) were added to the samples and homogenized by Precellys tissue homogenizer. Chloroform was added and samples were vortexed vigorously before phase separation through centrifugation. The aqueous phase was transferred on the QIAGEN RNeasy Mini Kit and RNA was isolated according to manufacturer’s instructions. cDNA was synthesized using the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems). Gene expression levels were determined by real-time PCR using Brilliant III Ultra-Fast SYBR Green QPCR Master Mix (Agilent Technologies) and Biorad CFX96 Real-Time PCR Detection System. Relative gene expressions were normalized to act-3 (T04C12.4) and tbg-1 (F58A4.8). mRNA levels. RNAi isolation from HEK293 cells was performed by the use of Invitrap Spin Universal RNA Mini Kit (Stratagene). cDNA was synthesized from 0.5 μg RNA using iScript cDNA synthesis kit from Bio-Rad. Quantitative PCR (qPCR) was performed using SsoFast EvaGreen Supermix (Bio-Rad) with transcript levels for GAPDH and beta-2-microglobulin (B2M) being monitored as reference transcripts. Relative Gene expression was calculated using the ΔΔCT method. The specificity of the PCR amplification was verified by melting curve analysis of the final products using Bio-Rad CFX 3.1 software. In each experiment three biological and three technical replicate samples were analyzed. The primer sequences used in the RT–PCR reactions are shown in Table S3.

Protein Extraction, Binding Assays, and Immunotechniques
Co-immunoprecipitations were performed on sonicated lysates from wild-type or mutant C. elegans that were resuspended in IP buffer [50 mM Tris pH 8.0, 100 mM NaCl, 0.5 mM EDTA, 4% Glycerol and 1% Triton X-100, 2 mM PMSF and Complete EDTA-Free Protease Inhibitor (Roche)]. For immunoprecipitation of CHN-1::FLAG and RNA was isolated according to manufacturer’s instructions. cDNA was synthesized using the High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems). Gene expression levels were determined by real-time PCR using Brilliant III Ultra-Fast SYBR Green QPCR Master Mix (Agilent Technologies) and Biorad CFX96 Real-Time PCR Detection System. Relative gene expressions were normalized to act-3 (T04C12.4) and tbg-1 (F58A4.8). mRNA levels. RNAi isolation from HEK293 cells was performed by the use of Invitrap Spin Universal RNA Mini Kit (Stratagene). cDNA was synthesized from 0.5 μg RNA using iScript cDNA synthesis kit from Bio-Rad. Quantitative PCR (qPCR) was performed using SsoFast EvaGreen Supermix (Bio-Rad) with transcript levels for GAPDH and beta-2-microglobulin (B2M) being monitored as reference transcripts. Relative Gene expression was calculated using the ΔΔCT method. The specificity of the PCR amplification was verified by melting curve analysis of the final products using Bio-Rad CFX 3.1 software. In each experiment three biological and three technical replicate samples were analyzed. The primer sequences used in the RT–PCR reactions are shown in Table S3.

Cell 169, 470–482.e1–e7, April 20, 2017
additional 1 hr at 4°C. Sepharose was washed six times with washing buffer (20 mM MOPS-KOH, pH 7.2, 100 mM KCl, 0.5% Tween) and 2 times with washing buffer without Tween. Sepharose-bound proteins were eluted using 0.1 M glycine-HCl, pH 3.5, precipitated with 10% TCA (trichloroacetic acid) and resolved in SDS sample buffer. Co-immunoprecipitated proteins were analyzed by SDS-PAGE and immunoblotting.

**Protein Expression and siRNA in Human Cells**

HEK293 or HeLa cells were seeded at approximately 30%–40% confluency and transfected 24 hr after plating. Transfection was done using jetPRIME (Peqlab) transfection reagent. After incubation over-night, cell medium was removed and fresh medium was added to the cells. 48 hr after transfection cells were lysed either for protein extraction or RNA purification. For expression of wild-type INSR in HEK293 cells pRT3-INSR-WT (Addgene) was used as template for cloning full-length cDNA of human INSR into pCMV-tag2b vector (Clonetech) (Table S3). The K1047R mutation was introduced into pCMV-tag2b-INSR by site-directed mutagenesis (Table S3). For overexpression of CHIP pCMV-tag2b-CHIP vector was used (Arndt et al., 2005). Expression of poly-Q proteins was induced by transient transfection with plasmids pEGFP-polyQ-25 and pEGFP-polyQ-103 (Westhoff et al., 2005). For efficient depletion two different siRNAs were used per gene (FlexiTube siRNAs CHIP 1+5 and FlexiTube siRNAs ATG7 1+3 (QIAGEN)). Allstars negative control siRNA (QIAGEN) was used as control siRNA.

**In Vitro Ubiquitylation**

10 μg of purified recombinant protein: His::CHIP, His::CHN-1, His::CHN-1(U-box), His::CHN-1(ΔU-box), His::(TPR)CHN-1, WWP-1::His or UFD-2::His was mixed with 1 μg of recombinant protein corresponding to the C terminus of human INSR (amino acids 987-1428), dINSR (amino acids 1815-2144) or DAF-2 (amino acids 1205-1928), and E1 (25 ng), E2 (UbcH5b; 400 ng), 2 μg of FLAG::ubiquitin or lysine lacking variant (Ub K0), energy regenerating solution (Boston Biochem) and Ubiquitin Conjugation Reaction Buffer (Enzo Life Sciences). Samples were incubated at 30°C for 1 hr, terminated by boiling for 5 min with SDS-sample buffer, and resolved by SDS-PAGE followed by immunoblotting using anti-insulin Rβ antibody (Santa Cruz) to monitor ubiquitylation of INSR, anti-DAF-2 antibody to monitor ubiquitylation of DAF-2, and anti-FLAG antibody (Sigma) to monitor E3 ligase activity.

**Stress Assays**

For oxidative stress assay, young adult worms were transferred to OP50-seeded NGM plates containing 5 mM paraquat. Survival of worms was monitored every day after transfer and scored as described for the lifespan assays. In heat shock experiments day 1 adult worms were transferred on chn-1 dsRNA expressing or control empty vector expressing HT115 bacteria seeded plates and incubated at 35°C in water bath for the indicated time. Survival of worms was scored as described for the lifespan assays. For ubiquitous dCHIP depletion RNAi flies were crossed to actin-Gal4 driver line and collected after 2 days of adulthood and placed on 20 mM paraquat (methylviologen (Sigma-Aldrich)) containing food. Survival rates were measured every other day. Wild-type flies were collected after 2 days of adulthood and placed on either H2O or 20 mM L-Canavanine (Sigma-Aldrich) containing food to induce protein misfolding.

**Statistical Analysis**

Kaplan and Meier survival curves of the lifespan analysis and median lifespan values were calculated using GraphPad Prism 5 software and Xlstat for Excel. The log-rank (Mantel–Cox) test was used to evaluate differences in survival and determine p values. Quantification of immunoblots was done with ImageJ 1.48v or Image Studio 4.0 software. Data obtained for changes in protein level are presented as fold change compared to the control with the control value determined in each independent experiment set to 1. Statistical significance was assessed by two-tailed paired Student’s t test using Excel software (Microsoft). Stress resistance assays and polyQ-aggregation assays were evaluated by two-tailed paired Student’s t test.
Figure S1. CHN-1 Modulates IIS in C. elegans, Related to Figure 1

(A) The loss-of-function alleles \textit{chn}-1(by155) and \textit{chn}-1(tm2692) lack CHN-1 protein. To detect CHN-1 protein indicated lysates of adult worms were subjected to immunoblot with anti-CHN-1 antibodies.

(B) Ubiquitous depletion of \textit{chn}-1 by RNAi results in reduced lifespan of wild-type worms (n = 6 independent experiments).

(C) Representative images of cytoplasmic and nuclear DAF-16::GFP localization in worms. Scale bar represents 100 µm.
Figure S2. CHN-1/CHIP Overexpression Affects Lifespan, Related to Figure 2

(A) Level of CHN-1::FLAG overexpression strain was analyzed by immunoblotting of indicated worm lysates (day 1 and 10 old animals). 
(B) Overexpression of chn-1 does not enhance lifespan of wild-type worms (n = 4 independent experiments). 
(C) Overexpression of dCHIP was driven by the use of the midgut specific TIGS-2 driver line and dCHIP levels were verified in gut extracts. Equal loading was verified by ponceau S staining (ponceau). 
(D) Flies of the genotype TIGS-2/ UAS-dCHIP were either placed on ethanol or RU486 (1 μg/ml or 5 μg/ml) containing food to induce dCHIP expression. dCHIP expression leads to toxicity in a dose-dependent manner and results in reduced lifespan. 
(E) Depletion of CHIP in HEK293 cells does not affect the expression level of PDK1, AKT, mTOR, or Hsp90. 
(F) Specificity of anti-DAF-2 antibodies was evaluated using daf-2(e1370) worms expressing thermolabile DAF-2 protein. Worms were grown at 25°C until day 1 of adulthood, lysed, and analyzed by western blotting using DAF-2 specific antibodies.
Figure S3. CHN-1/CHIP-Dependent Ubiquitylation of the INSR, Related to Figure 3

(A) CHN-1 protein level does not significantly change during aging. CHN-1 protein level was evaluated by western blotting using CHN-1 specific antibodies in whole worm lysates of adult worms (representative immunoblots are shown of n = 3 experiments).

(B and C) Ubiquitylation of INSR was carried out as indicated using CHN-1, CHN-1(DU-box), CHN-1(U-box), (TPR)CHN-1, CHIP, UFD-2, and WWP-1 as ubiquitin ligases.

(D) Mutations in the TPR domain of CHN1 ((TPR)CHN-1) abrogate INSR ubiquitylation. The ubiquitin ligase WWP-1 is unable to ubiquitylate INSR. Ubiquitylation reaction was carried out using FLAG-tagged ubiquitin (FLAGUb) in the presence of E. coli BL21 lysates. Activity of used E3 enzymes was evaluated by western blotting using anti-FLAG specific antibodies showing ubiquitylated bacterial proteins.

(E) In vitro ubiquitylated DAF-2, INSR were subjected to mass spectrometry to identify the lysine residues used for ubiquitin attachment. Conserved residues are indicated in red. Previously published residues are marked as follows: #O’Rahilly et al., 1991; +Kim et al., 2011; *Udeshi et al., 2013.
Figure S4. Defective Ubiquitylation Contributes to Elevated DAF-2\textsuperscript{2K390E2S} Protein Levels, Related to Figure 5

(A) Loss of \textit{chn-1} does not significantly increase the level of DAF-2\textsuperscript{2K390E2S} protein (mean values were obtained in \( n = 3 \) independent experiments).
Figure S5. Role of CHIP in Proteostasis, Related to Figure 6

(A and B) CHN-1 function during development is not important for lifespan regulation.

(C) Post developmental knockdown of chn-1 results in higher sensitivity against heat stress (35°C) as compared to wild-type worms (mean values were obtained in n = 4 independent experiments).

(D) CHN-1 protein level does not change when exogenous stress is applied to day 1 adult worms.

(E) Treatment with L-canavanine (20 mM) leads to a strong stabilization of dINSR in adult head extracts of aged wild-type flies (3 weeks old).

(F) polyQ40 exerts mild toxicity in the body-wall muscle cells of chn-1 depleted worms assessed by counting body bending of individual animals (1st or 5th day of adulthood).

(G) Expression of aggregation prone polyQ-103 in HEK293 cells reduces INSR turnover rate as determined by mRNA/protein ratio (mean values were obtained in n = 3 independent experiments).

(C and G) Data are means ± SEM. *p < 0.05, **p < 0.01, ***p < 0.001.
Figure S6. DAF-2 Level Upon Dietary Restriction, Related to Figure 5

(A) The age-related stabilization of DAF-2 in chn-1 mutants is not further increased in eat-2(ad465) worms. Western blot analysis of DAF-2 protein was carried out by using anti-DAF-2 antibodies on whole-worm lysates of indicated age.
