INTRODUCTION

Injuries that affect the presacral space are rare, and are part of a heterogeneous group of entities of primary concern to colorectal surgeons. These lesions are located in anatomically difficult area to be addressed, hence the need for prior surgical planning, as well as knowledge of the major diseases that affect this region.

The incidence of these lesions varies from 1: 40,000 to 1: 630,0008, being more common in females between 40 and 60 years8.

CASE REPORT

Man of 94 years showed changes in bowel habits few months ago. Digital rectal examination showed solid pelvic mass with no apparent invasion of the rectal mucosa; it is not possible to predict its upper limit. Computed tomography of the pelvis showed solid-cystic lesion in proximity to the sacrum bone and rectum, with apparent cleavage plane between adjacent structures (Figure 1). He underwent transperitoneal resection of the lesion. Major bleeding occurred during surgery, which was controlled, requiring blood transfusion with four blood cell concentrate units.

Postoperative was without morbidity and discharged on the 7th day after surgery. The pathology confirmed it was schwannoma of low-grade without evidence of malignancy (Figure 2).

DISCUSSION

Although most retrorectal lesions are congenital, most patients do not have a previous positive family history; the most common clinical presentation is asymptomatic mass found to proctologic examination5. The retrorectal masses are palpable on rectal exam by up to 97% of cases7.

Due to the angular change caused by the puborectalis muscle mass patients often have changes in bowel habits with a tendency to constipation, feeling of incomplete evacuation or thin stools.

A flexible sigmoidoscopy is useful for viewing the invasion of the rectal mucosa by the tumor and its upper limit, for correct surgical management.

Imaging tests are essential for accurate diagnosis, and the MRI is superior to CT in the characterization of pelvic masses for the presence of bone invasion or neural involvement2.

Treatment is mainly surgical. Many of these injuries,
despite the benign appearance, may contain malicious elements or potentiality for malignant degeneration in the medium term, and the risk of infection in benign cysts. This patient was discharged on the seventh postoperative day, with uneventful recovery.

The resection of the coccyx is not recommended unless there is suspicion of involvement by malignant disease. As far as rectum is often densely adhered to the tumor, should be carried out careful dissection, to avoid injury.

There are three types of surgical approach: anterior or abdominal transperitoneal or extra-peritoneal, conventional or laparoscopic access; the posterior approach; and combined abdominosacral route.

The anterior approach is used for high lesions (with caudal end until the level S4) without evidence of sacral engagement. The rectum is folded laterally and the median sacral artery is usually linked with the dissection and tumor is enucleated.

The latter approach is preferred for smaller, benign lesions that do not extend beyond the level S4. This route is used when the presence of neural involvement or for better viewing and preservation.

Tumors of major proportions exceeding proximal and distal S4 level are more easily operated via abdominosacral route. The resection can be performed synchronously with the patient in the lateral position or sequentially with the change in position after each stage of the operation. The benefit of the combined approach includes the ability to display structures such as ureter, nerve and sacral iliac vessels, particularly important in cases where there is the need to perform partial sacrectomy, especially in chordoma.

The adjuvant therapies have only a secondary role in the management of tumors in retrorectal space. In cases where radical surgery is contraindicated, palliative radiotherapy has been carried out, except for chordoma, classically radioresistant.

The survival of benign tumors approaches to 100% in most studies. However relapse is not uncommon. Development of cysts relapses up to 15%. Approximately 9-45% of retrorectal malignant tumors are most commonly solids than cystic, with recurrence rates of 45%; five year survival rate is about 8 to 17%.

AN EXTREMELY RARE COMPLICATION OF MECKEL’S DIVERTICULUM: ENTEROCUTANEOUS FISTULIZATION OF UMBILICAL HERNIA

Complicação rara de divertículo de Meckel: fistulização enterocutânea através de hérnia umbilical

INTRODUCTION

Meckel’s diverticulum is the most common malformation of the gastrointestinal tract with an incidence of 2% of the population. This congenital anomaly results from incomplete yolk duct development. Meckel’s diverticulum has a complication rate of 4-6%. Most common complications are haemorrhage, perforation, obstruction and inflammation. It is mostly asymptomatic and most often diagnosed when complications occur. Also it may be diagnosed incidentally during laparoscopy or laparotomy for unrelated conditions.

Fistula formation (between abdominal organs), herniation (of abdominal wall), and Littre hernia (protrusion of a Meckel’s diverticulum through an abdominal wall defect) are well-described complication. However, umbilical herniation of Meckel’s diverticulum is rare. Herein is presented a case with enterocutaneous fistula between Meckel’s diverticulum and umbilicus associated with umbilical hernia.

CASE REPORT

A 40-year-old man was admitted to the department of General Surgery with a 24 h history of abdominal pain focused on the umbilical region, as well as fever, anorexia and vomiting. He had a history of previous umbilical abscess drainage five years ago. He reported no other medical history. Examination of the abdomen showed tenderness over the umbilical region without abdominal guarding and rigidity. A leakage of intestinal fluid through an opening (an external fistula orifice) was determined inside the umbilicus. There was no increase in local heat, swelling or edema. The laboratory findings, including complete blood count and electrolytes, and abdominal X-ray showed no abnormality. Abdominal ultrasound showed a well-limited...
