- β-amyloid

Abstract
Purpose: Some reports have shown neuroprotective effects of caffeine in several neurodegenerative disorders. However, its mechanism of action is not completely clear. Therefore, the aim of this study was to explore the interference of ryanodine, N-methyl-D-aspartate (NMDA) and adenosine modulators with the neuroprotective effects of caffeine against β-amyloid (Aβ) neurotoxicity in the SHSY5Y cells.

Methods: The SHSY5Y cells were treated with Aβ[23-35] (20µM) and/or caffeine (0.6 and 1mM), or both for 24 hours. Adenosine (20, 40, 60, 80, 100µM), NMDA (20, 50, 70, 90µM), dantrolene (2, 4, 6, 8, 10µM) were also added to the medium and incubated for 24 hours. The cell viability was measured via the MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) method. The data were analyzed using one-way ANOVA followed by Bonferroni test.

Results: Caffeine at the all used concentrations (0.6, 0.8, 0.9, 1, and 3mM) significantly protected neuronal cells against Aβ neurotoxicity. Adenosine at the concentrations of 20, 40, 80 and 100µM diminished the neuroprotective effects of caffeine (0.6 and 1mM) against Aβ neurotoxicity. NMDA at the concentrations of 20, 50, 70 and 90µM blocked caffeine (0.6 and 1mM) neuroprotective effects. Dantrolene at the concentration of 2, 4, 6, 8 and 10µM diminished the neuroprotective effects of caffeine (0.6mM) and at the concentrations of 2 and 10µM impede caffeine (1mM) neuroprotection against Aβ neurotoxicity.

Conclusion: Caffeine produced neuroprotective effect against Aβ neurotoxicity. Blockade of adenosine and NMDA receptors, as well as the activation of ryanodine receptors, may contribute to the neuroprotective effects of caffeine.

Introduction
Extracellular aggregation of β-amyloid peptides (Aβ) and hyperphosphorylated tau protein (neurofibrillary tangles) may be the most important causes of neural degeneration in Alzheimer’s disease (AD). Moreover, accumulating data have implied that deregulated calcium signaling may have an important contribution to the neural cell death in AD. Interestingly, altered intracellular calcium homeostasis emerges earlier than neuropathological abnormalities observed in AD. Calcium is an important signal transduction molecule which is involved in a wide range of neuronal functions like cell growth, differentiation, metabolism, exocytosis, and apoptosis. Several neuronal systems, including N-methyl-D-Aspartate (NMDA), adenosine and ryanodine receptors maintain the intracellular concentration of calcium within a narrow normal range. On the other hand, ryanodine, NMDA and adenosine receptors have possible roles in the pathophysiology and treatment of AD. Thus, these receptors may be the targets of neuroprotective agents in AD.

Caffeine is the most popular psychoactive drug around the world with important modulatory effects on intracellular calcium in the central nervous system (CNS). Caffeine effects may be related to the non-specific modulation of several systems in the CNS. At the normal daily consumption (2.4 to 4.0 mg/kg or 2 to 4 cups of coffee per person), the primary target of caffeine is the non-selective antagonism of adenosine receptors. Ryanodine receptors are the other physiological targets of caffeine in the CNS which mediates caffeine-induced intracellular calcium release. In contrast, caffeine effects on the NMDA receptors are not fully elucidated. Recent evidence has shown that caffeine exerts profound effects on motor, behavior, information processing, and cognitive performance. It has been also demonstrated that caffeine can produce neuroprotective effects in different neurodegenerative diseases. In-vivo and in-vitro studies have also shown that caffeine or coffee has protective effects against AD. However, the exact mechanism of...
neuroprotective effects of caffeine in AD is not completely clear. Therefore, the aim of this study was to explore the interference of ryanodine, NMDA and adenosine modulators with the neuroprotective effects of caffeine against Aβ neurotoxicity in the SHSY5Y cell line.

Materials and Methods

Materials

Human SHSY5Y cells were purchased from Pasteur Institute (Tehran, Iran). Cell culture materials including DMEM/F12, FBS (fetal bovine serum), and Penicillin-Streptomycin were obtained from Gibco® life technologies™ (New York, USA). Aβ25-35, caffeine, dantrolene sodium salt, NMDA, and adenosine were purchased from Sigma-Aldrich (St. Louis, USA).

Neuronal Cell Culture

The human SHSY5Y cells were grown in DMEM/F12 (1:1) media supplemented with 10% fetal bovine serum, 100U/ml penicillin, and 100µg/ml streptomycin. The cells were seeded at a density of 10^5 cells/well in the 96-well plates for the MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) experiments. The plates were maintained at 37°C in 95% humidified atmosphere (air) with 5% CO₂. After 24 hr of incubation, the cells were treated with Aβ and/or other agents.

Aβ25–35 Preparation

Aβ25–35 was dissolved in sterile distilled water at a concentration of 2µg/μl and kept at −70 °C until use. For the aggregation process, Aβ25–35 was incubated at 37 °C for 4 days before the administration in the cell culture.

Treatment

Caffeine, dantrolene (a ryanodine receptor antagonist), adenosine and NMDA were dissolved in PBS (Phosphate Buffered Solutions). The effective concentration of Aβ25-35 and caffeine was obtained through dose response experiments and MTT assay. On the day of treatment, the serum-free medium was treated with Aβ23-35 (20µM, selected according to pilot studies) and/or caffeine (0.6 and 1mM, selected according to pilot studies), or both for 24 hours. Adenosine (20, 40, 60, 80, 100µM), NMDA (20, 50, 70, 90µM), dantrolene (2, 4, 6, 8, 10µM) were also added to the medium and incubated for 24 hours.

Cell Viability Assay

Twenty-four hours after treatments, 5 mg/ml MTT reagent was added to the cell culture media. Four hours later, the media was gently removed and the precipitations in each well were dissolved in 100 μl of DMSO. We measured the absorbance at 570 nm using a microplate reader (Synergy HT, Biotek®) as an index of neuronal viability.

Statistical analysis

The variables were analyzed using one-way ANOVA followed by Bonferroni test. The significance level was considered as <0.05. All analyses were performed using SPSS software version 23.

Results and Discussion

Aβ at a concentration of 20µM decreased about 71% in the neural viability in the SY-SY5Y cell lines compared with the control group. Moreover, our analysis showed that different concentrations of caffeine significantly protected neuronal cells against Aβ neurotoxicity (F(df)= 16.81(6), p= 0.000). We chose two concentration of caffeine (0.6 and 1 mM) to evaluate the interaction of adenosine, NMDA, and dantrolene with caffeine neuroprotective effects. Adenosine at the concentrations of 20, 40, 60, 80 and 100µM diminished the neuroprotective effects of caffeine (0.6mM) against Aβ neurotoxicity (F(9)= 21.35, p=0.000) (Figure 1). Moreover, adenosine at the concentrations of 20, 40, 80 and 100µM blocked caffeine (1mM) neuroprotective effects against Aβ neurotoxicity (F(9)= 8.77, p=0.000) (Figure 2). There was a significant difference between different concentrations of adenosine (without caffeine) against Aβ neurotoxicity (F(3)=4.902, p=0.019). The pairwise comparison showed that adenosine only at a concentration of 80µM reduced Aβ neurotoxicity compared with the Aβ-treated group (p=0.036).

Figure 1. Adenosine affected caffeine (0.6mM) neuroprotective effects against Aβ neurotoxicity in the SHSY5Y neuroblastoma cells. Data are the mean ± standard error of four experiments and were analyzed using one-way ANOVA followed by Bonferroni test. ** shows the significance at 0.001 compared with the β-amyloid (Aβ) + caffeine (0.6mM)-treated group, and † significance at 0.05 compared with the Aβ-treated group. Cell viability was assessed via MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) test.
Caffeine mechanism against Aβ neurotoxicity

Advanced Pharmaceutical Bulletin, 2017, 7(4), 579-584

Figure 2. Adenosine affected caffeine (1mM) neuroprotective effects against Aβ neurotoxicity in the SHSY5Y neuroblastoma cells. Data are the mean ± standard error of four experiments and were analyzed using one-way ANOVA followed by Bonferroni test. * and ** shows the significance at 0.05 and 0.001 compared with the β-amyloid (Aβ) + caffeine (1mM)-treated group, respectively, and † significance at 0.05 compared with the Aβ-treated group. Cell viability was assessed via MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) test.

Dantrolene at the concentration of 2, 4, 6, 8 and 10μM diminished the neuroprotective effects of caffeine (0.6mM) against Aβ neurotoxicity (F(7)= 43.75, p=0.000) (Figure 3). Furthermore, dantrolene at the concentrations of 2 and 10μM impeded the caffeine (1mM) neuroprotection against Aβ neurotoxicity (F(7)=16.26, p=0.000)(Figure 4). In contrast, dantrolene at the concentrations of 4, 6 and 8μM had no effect on the caffeine (1mM) neuroprotection (Figure 4). There was a significant difference between the different concentration of dantrolene (without caffeine use) against Aβ neurotoxicity (F(4)= 8.81, p=0.001), though the pairwise comparison showed no significant difference between each concentration of dantrolene and the Aβ-treated group (p>0.05).

Figure 3. Dantrolene affected caffeine (0.6mM) neuroprotective effects against Aβ neurotoxicity in the SHSY5Y neuroblastoma cells. Data are the mean ± standard error of four experiments and were analyzed using one-way ANOVA followed by Bonferroni test. * shows the significance at 0.05 and 0.001 compared with the β-amyloid (Aβ) + caffeine (0.6mM)-treated group, respectively, and † is significance at 0.001 compared with the vehicle-treated group. Cell viability was assessed via MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) test.

Figure 4. Dantrolene affected caffeine (1mM) neuroprotective effects against Aβ neurotoxicity in the SHSY5Y neuroblastoma cells. Data are the mean ± standard error of four experiments and were analyzed using one-way ANOVA followed by Bonferroni test. * and ** shows the significance at 0.001 compared with the β-amyloid (Aβ) + caffeine (1mM)-treated group. Cell viability was assessed via MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) test.

NMDA at the concentrations of 20, 50, 70 and 90 μM inhibited caffeine (0.6 and 1mM) neuroprotective effects against Aβ neurotoxicity (F(6)= 23.29, p=0.000 and F(6)= 42.95, p=0.000, respectively) (Figure 5 and 6). There was a significant difference regarding neuronal death between different concentrations of NMAD alone groups, Aβ-treated group and the vehicle treated group (F(3)= 0.657, p=0.594). Each concentration of NMAD (20, 80 and 120μM) significantly reduced neuronal viability compared with the vehicle-treated group (p<0.05) (Figure 5). However, there was no significant difference between NMAD alone groups and Aβ-treated group (p>0.05) (Figure 5).

Figure 5. N-Methyl-D-Aspartate (NMAD) affected caffeine (0.6mM) neuroprotective effects against Aβ neurotoxicity in the SHSY5Y neuroblastoma cells. Data are the mean ± standard error of four experiments and were analyzed using one-way ANOVA followed by Bonferroni test. * and ** shows the significance at 0.05 and 0.001 compared with the β-amyloid (Aβ) + caffeine (0.6mM)-treated group, respectively, and † is significance at 0.001 compared with the vehicle-treated group. Cell viability was assessed via MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide) test.
Adenosine is an endogenous neuromodulator that influences many functions in the CNS. Adenosine fulfills homeostatic and neuromodulatory roles in the CNS by controlling neurotransmission and neuronal excitability. Although adenosine has four receptors (A<sub>1</sub>R, A<sub>2A</sub>R, A<sub>2B</sub>R, and A<sub>3</sub>R), most of its functions might be related to A<sub>1</sub> and A<sub>2A</sub> receptors. Adenosine and its receptors have important roles in the pathogenesis of neurodegenerative disorders like AD, though the exact function of this neuromodulator should be elucidated. It has been suggested that caffeine neuroprotective effects may be related to the inhibition of adenosine receptors. Our study showed that adenosine impaired neuroprotective effects of caffeine against Aβ neurotoxicity. Thus, the results of our study imply that the blockade of adenosine receptors may be responsible, at least partly, for the neuroprotective effects of caffeine in the cellular model of AD. In this regard, it has been shown that blockade of A<sub>1</sub> and A<sub>2A</sub> receptors produces neuroprotective effects. Our study showed that dantrolene, a ryanodine receptor antagonist, reduced neuroprotective effects of caffeine against Aβ neurotoxicity. Dantrolene modulates intracellular calcium by stabilizing and inhibiting RyR. It can be implicated that caffeine neuroprotective effect may contribute, at least in part, to the RyR-mediated calcium release from the endoplasmic reticulum. There are considerable controversies about the intracellular calcium and RyR roles in the pathogenesis of AD. In agreement with our results, systemic administration of dantrolene has increased amyloid plaque formation and deteriorated hippocampal neuronal damage in a transgenic model of AD. Accordingly, it has been proposed that increased RyR activity may attempt to maintain intracellular calcium homeostasis in the early stages of AD. In line with this, it has been shown that inability of neurons to up-regulate RyR3 made them more vulnerable to the insults like Aβ exposure, excitotoxicity, and oxidative stress. Thus, RyR hyperactivity in AD may be protective and/or a part of a mechanism to compensate calcium deregulation in AD. In contrast, short-term treatment with dantrolene has stabilized intracellular calcium, decreased amyloid load, and reversed cognitive decline and memory impairments in various AD mouse models.

NMDA receptors are glutamate receptors with high permeability to calcium that have critical roles in synaptic plasticity, long-term potentiation and learning and memory. In contrast, hyperactivation of these receptors may lead to disrupting calcium homeostasis, neuronal damage, and excitotoxicity. Accumulating evidence has been shown that NMDA receptor-mediated excitotoxicity may be involved in the Aβ neurotoxicity. Our study showed that NMDA reduced caffeine neuroprotective effects against Aβ neurotoxicity. Thus, it can be implicated that caffeine neuroprotective effects may in part be related to the NMDA blockade. To best of our knowledge, there is very limited information in the literature about caffeine interaction with NMDA receptors. However, caffeine may mimic NMDA antagonist effects in some brain regions and its interaction with NMDA receptors may exert beneficial effects in neurodegenerative disorders. Thus, it is possible to assume that direct or indirect blockade of NMDA receptors may contribute to the caffeine neuroprotective effects.

**Limitations**

The main limitation of this study may be the administration of non-specific modulators of adenosine and RyR. Thus, using specific modulators of these receptors may help to further clarify exact mechanism of action of caffeine in managing neurodegenerative disorders.

**Conclusion**

Caffeine produced neuroprotective effect against Aβ neurotoxicity in SHSY5Y cell line. The exact
mechanism of caffeine neuroprotective effects is not completely clear. However, blockade of adenosine and NMDA receptors, as well as activation of RyR receptors, may contribute to the neuroprotective effects of caffeine. However, future studies with more selective and specific modulators of adenosine and RyR may confirm the results of this study. Moreover, we cannot rule out other mechanisms that may be involved in the neuroprotective effects of caffeine against Aβ neurotoxicity.
