Abstract
In this paper, the notion of dimension preserving approximation for real-valued bivariate continuous functions, defined on a rectangular domain $\square$, has been introduced and several results, similar to well-known results of bivariate constrained approximation in terms of dimension preserving approximants, have been established. Further, some clue for the construction of bivariate dimension preserving approximants, using the concept of fractal interpolation functions, has been added. In the last part, some multi-valued fractal operators associated with bivariate $\alpha$-fractal functions are defined and studied.

Keywords Fractal dimension · Fractal interpolation · Fractal surfaces · Bernstein polynomials · Bivariate constrained approximation

1 Introduction
Following the seminal work of Barnsley [2], Navascués [17, 18] studied the approximation of functions using their fractal counterparts termed as $\alpha$-fractal functions. In the same vein, Verma and Masspoust [22] recently introduced the notion of dimension...
preserving approximation. We use \( \text{dim} \) and \( Gr(f) \) respectively to represent fractal dimension and graph of a function of \( f \).

Various concepts of fractal dimensions are available but we cover only those fractal dimensions that are suitable for this article. We only need to mention the Hausdorff dimension, the box dimension, and the packing dimension defined for nonempty subsets of \( \mathbb{R}^n, n \in \mathbb{N} \), and denoted by \( \text{dim}_H \), \( \text{dim}_B \) and \( \text{dim}_P \) respectively.

The following relations are established between these fractal dimensions. (see [9, 15]):

\[
\text{dim}_H F \leq \text{dim}_B F \leq \text{dim}_B F
\]

and

\[
\text{dim}_H F \leq \text{dim}_P F \leq \text{dim}_B F.
\]

The class of all real-valued continuous functions on \( \Box := I \times J \) is defined by \( C(\Box) \), where \( I = [a, b] \) and \( J = [c, d] \).

For a bivariate function \( f \), we denote the derivative of \((k, l)\)-th order by \( D^{(k,l)} f \), that is, \( D^{(k,l)} f := \frac{\partial^{k+l} f}{\partial x^k \partial y^l} \). Let

\[
C^{m,n}(\Box) = \{ f: \Box \to \mathbb{R}; D^{(k,l)} f \in C(\Box), \forall \ 0 \leq k \leq m, \ 0 \leq l \leq n \}.
\]

If \( D^{(m,n)} f(x) \geq 0, \forall \ x \in \Box \), then we say the function \( f \) is \((m, n)\)-convex. Let \( g \in C(\Box) \) such that \( \text{dim}(Gr(g)) > 2 \). We may refer to [21] for the existence of such functions. The function \( f : \Box \to \mathbb{R} \) defined by \( f(x, y) := \int_a^x \int_c^y g(t, s) dt ds \) satisfies the following:

\[
\text{dim}(Gr(f)) = 2 \quad \text{and} \quad \text{dim} Gr(D^{(1,1)} f) = \text{dim}(Gr(g)) > 2,
\]

where \( \text{dim} \) denotes a fractal dimension.

Recall that the tensor product Bernstein polynomial on \( \Box \) is defined as:

\[
B_{m,n}(f)(x, y) = \sum_{i=0}^{m} \sum_{j=0}^{n} f \left( a + \frac{i(b-a)}{m}, c + \frac{j(d-c)}{n} \right) \left( \begin{array}{c} m \\ i \end{array} \right) \left( \begin{array}{c} n \\ j \end{array} \right) (x-a)^i (b-x)^{m-i} (y-c)^j (d-y)^{n-j}.
\]

Let us approximate a function \( f \in C^{k,l}(\Box) \) by \( B_{m,n}(f) \), then we have the following:

- \( B_{m,n}(f) \to f \) uniformly on \( \Box \).
- \( (D^{(k,l)} B_{m,n}(f)) \to D^{(k,l)} f \) uniformly on \( \Box \).
On bivariate fractal approximation

- Since $B_{m,n}(f)$ and $D^{(k,l)}(B_{m,n}(f))$ are polynomials, then $\dim \left( Gr(D^{(k,l)}(B_{m,n}(f))) \right) = \dim(Gr(B_{m,n}(f))) = \dim(Gr(f)) = 2$.

We refer the reader to [11] for several properties of bivariate Bernstein polynomials. The above items may conclude that the approximation by Bernstein polynomials maintains the smoothness of a function but not (necessarily) the dimensions of its partial derivatives.

The present paper explores the approximation perspective relative to fractal dimension of a function and its partial derivatives.

The paper is structured as follows. In Section 1, we give a brief introduction and some preliminaries needed for the paper. In Section 2, we start to prove some results regarding dimension preserving approximation. In Section 3, we define some multi-valued mappings which are defined with the help of bivariate $\alpha$-fractal functions, and establish some properties of them.

## 2 Dimension preserving approximation of bivariate functions

Firstly, we mention the following result required for our paper:

**Lemma 2.1** ([22], Lemma 3.1) Let $A \subset \mathbb{R}^m$ and $f, g : A \to \mathbb{R}^n$ be continuous functions. Then,

$$\dim_H(Gr(f + g)) = \dim_H(Gr(g)) \quad \text{and} \quad \dim_P(Gr(f + g)) = \dim_P(Gr(g))$$

provided that $f$ is a Lipschitz function.

**Remark 2.2** Note that the above lemma is also true for box dimensions.

Let us denote the class of $Y$-valued Lipschitz functions on $X$ by $\mathcal{L}ip(X, Y)$, where $(X, d_X)$ is a compact metric space and $(Y, \| \cdot \|_Y)$ is a normed linear space. Note that this space is a dense subset of $\mathcal{C}(X, Y)$ with respect to the supremum norm.

In view of Lipschitz invariance property of dimension, one may conclude that the upcoming theorem holds for all aforementioned dimensions.

**Theorem 2.3** Let $\dim(X) \leq \beta \leq \dim(X) + \dim(Y)$. Then the set $S_\beta := \{ f \in \mathcal{C}(X, Y) : \dim(Gr(f)) = \beta \}$ is dense in $\mathcal{C}(X, Y)$.

**Proof** Let $f \in \mathcal{C}(X, Y)$ and $\epsilon > 0$. Using the density of $\mathcal{L}ip(X, Y)$ in $\mathcal{C}(X, Y)$, there exists $g$ in $\mathcal{L}ip(X, Y)$ such that

$$\| f - g \|_{\infty, Y} < \frac{\epsilon}{2}.$$

Further, we consider a non-vanishing function $h \in S_\beta$. Let $h_* = g + \frac{\epsilon}{2\|h\|_{\infty, Y}} h$, which immediately gives

$$\| g - h_* \|_{\infty, Y} \leq \frac{\epsilon}{2}.$$
This together with Lemma 2.1 implies that $\dim(Gr(h_*)) = \dim(Gr(h)) = \beta$. Hence, we have $h_* \in S_\beta$ and
\[
\|f - h_*\|_{\infty, Y} \leq \|f - g\|_{\infty, Y} + \|g - h_*\|_{\infty, Y} < \epsilon.
\]
Thus, the proof of the theorem is complete. \(\square\)

To the best of our knowledge, the univariate version of the next theorem is well-known, however, we could not find a proof of the theorem in bivariate setting. Hence, we write a detailed proof of it.

**Theorem 2.4** Let $(f_k)$ be a sequence of differentiable functions on $\mathbb{D}$. Assume that for some $(x_0, y_0) \in \mathbb{D}$, the sequences $(f_k(x_0, \cdot))$ and $(f_k(\cdot, y_0))$ converges uniformly on $[c, d]$ and $[a, b]$ respectively. If $(D^{(1,1)} f_k)$ converges uniformly on $\mathbb{D}$, then $(f_k)$ converges uniformly on $\mathbb{D}$ to a function $f$, and
\[
D^{(1,1)} f(x) = \lim_{k \to \infty} D^{(1,1)} f_k(x),
\]
for every $x \in \mathbb{D}$.

**Proof** Let $\epsilon > 0$. Since $(D^{(1,1)} f_k)$ converges uniformly, there exists $N_1 \in \mathbb{N}$ such that
\[
|D^{(1,1)} f_k(x) - D^{(1,1)} f_m(x)| < \frac{\epsilon}{4(b - a)(d - c)}, \quad \forall \; x \in \mathbb{D}, \; k, m \geq N_1.
\]

By the mean-value theorem, see, for instance, [20, Theorem 9.40], we have
\[
\begin{align*}
|f_k(x + h, y + k) - f_m(x + h, y + k) - f_k(x + h, y) & + f_m(x + h, y) + f_k(x, y + k) + f_m(x, y + k) \\
& + f_k(x, y) - f_m(x, y)| \\
& = hk \left| D^{(1,1)} f_k(t, s) - D^{(1,1)} f_m(t, s) \right| \\
& \leq hk \max_{(t,s)\in \mathbb{D}} \left| D^{(1,1)} f_k(t, s) - D^{(1,1)} f_m(t, s) \right| \\
& \leq \frac{\epsilon}{4(b - a)(d - c)} hk \\
& \leq \frac{\epsilon}{4}.
\end{align*}
\]

By the hypothesis for $(x_0, y_0) \in \mathbb{D}$, one can choose $N_0 > N_1 \in \mathbb{N}$ such that
\[
|f_k(x_0, y) - f_m(x_0, y)| < \frac{\epsilon}{4} \quad \forall \; k, m \geq N_0
\]
and
\[
|f_k(x_0, y) - f_m(x_0, y)| < \frac{\epsilon}{4} \quad \forall \; k, m \geq N_0.
\]
Now, using the above estimates and Equation 2.1, we have

$$\left| f_k(x, y) - f_m(x, y) \right| \leq \frac{\epsilon}{4} + |f_k(x, y_0) - f_m(x, y_0)| + |f_k(x_0, y) - f_m(x_0, y)|$$

$$< \frac{\epsilon}{4} + \frac{\epsilon}{4} + \frac{\epsilon}{4} + \frac{\epsilon}{4}$$

$$= \epsilon,$$

for every \((x, y) \in \square\) and \(k, m \geq N_0\). This immediate confirms the uniform convergence of \((f_k)\). The rest part of the proof follows by routine calculations. Therefore, we complete the proof.

\[\square\]

**Lemma 2.5** Let \(f : I \to \mathbb{R}\) be a Lipschitz map and \(g : J \to \mathbb{R}\) a continuous function. A mapping \(h : \square \to \mathbb{R}\) is defined by

\[h(x, y) = f(x) + g(y),\]

then

\[\text{dim}_H(Gr(h)) = \text{dim}_H(Gr(g)) + 1.\]

**Proof** Proof follows by defining a bi-Lipschitz mapping from \(Gr(h)\) to the set \\{(x, y, g(y)) : x \in I, \ y \in J\}. \[\square\]

Here, let us recall some dimensional results for univariate functions. Mauldin and Williams [16] considered the following class of functions:

\[W_b(x) := \sum_{n=-\infty}^{\infty} b^{-\alpha n} [\phi(b^n x + \theta_n) - \phi(\theta_n)].\]

where \(\theta_n\) is an arbitrary real number, \(\phi\) is a periodic function with period one and \(b > 1, 0 < \alpha < 1\). They showed that for a large enough \(b\) there exists a constant \(C > 0\) such that \(\text{dim}_H(Gr(W_b))\) is bounded below by \(2 - \alpha - (C/ \ln b)\).

Further, Shen [21] proved some dimensional results for the following class of functions:

\[f^{\phi}_{\lambda,b}(x) := \sum_{n=0}^{\infty} \lambda^n \phi(b^n x),\]

where \(b \geq 2\) and \(\phi\) is a real-valued, \(\mathbb{Z}\)-periodic, non-constant, \(C^2\)-function defined on \(\mathbb{R}\). For instance, he proved that there exists a constant \(K_0\) depending on \(\phi\) and \(b\) such that if \(1 < \lambda b < K_0\) then

\[\text{dim}_H(Gr(f^{\phi}_{\lambda,b})) = 2 + \frac{\log \lambda}{\log b}.\]
For \( f \in C^{1,1}(\square) \), we get \( \text{dim}(Gr(f)) = 2 \). However, no conclusion can be drawn for dimensions of its partial derivatives. This is evident from the following example:

let Weierstrass-type nowhere differentiable continuous function \( W : I \to \mathbb{R} \) be as in [21] with \( 1 \leq \text{dim}(Gr(W)) \leq 2 \). Now, we define \( h : \square \to \mathbb{R} \) by

\[
h(x, y) = W(x) + y.
\]

Here, by Lemma 2.5, we obtain \( 2 \leq \text{dim}(Gr(h)) = \text{dim}(Gr(W)) + 1 \leq 3 \). Then for the function \( f \) defined by

\[
f(x, y) := \int_a^x \int_c^y h(t, s)dt\,ds,
\]

we have \( \text{dim}(Gr(f)) = 2 \) and \( 2 \leq \text{dim}(Gr(D^{(1,1)}f)) = \text{dim}(Gr(h)) \leq 3 \).

**Theorem 2.6** Let \( f \in C^{1,1}(\square) \) and \( 2 \leq \beta \leq 3 \). Then we have a sequence \( (f_k) \) in \( C^{1,1}(\square) \) such that \( \text{dim}(Gr(D^{(1,1)}f_k)) = \beta \) and \( f_k \to f \) uniformly on \( \square \).

**Proof** In view of the Theorem 2.3, there exists a sequence \( (g_k) \) in \( C(\square) \) such that \( \text{dim}(Gr(g_k)) = \beta \) and \( g_k \to D^{(1,1)}f \) uniformly on \( \square \). Further, let us consider a function \( f_k : \square \to \mathbb{R} \) defined by

\[
f_k(x, y) := \int_a^x \int_c^y g_k(t, s)dt\,ds.
\]

Then \( D^{(1,1)}f_k = g_k \) and \( D^{(1,1)}f_k \to D^{(1,1)}f \) uniformly. Next, we have that \( (f_k(a, y)) \to 0 \) and \( (f_k(x, c)) \to 0 \) uniformly on \( J \) and \( I \) respectively. Now, Theorem 2.4 provides the proof. \( \square \)

**Theorem 2.7** Let \( f \in C(\square) \) with \( f(x) \geq 0 \) \( \forall x \in \square \). Then, for a given \( \epsilon > 0 \), there exists \( g \in \mathcal{S}_\beta \) satisfying the following:

\[
g(x) \geq 0 \ \forall \ x \in \square \text{ and } \|f - g\|_\infty < \epsilon.
\]

**Proof** Let \( \epsilon > 0 \). Theorem 2.3 yields an element \( h \in \mathcal{S}_\beta \) such that

\[
\|f - h\|_\infty < \frac{\epsilon}{2}.
\]

We define

\[
g(x) := h(x) + \frac{\epsilon}{2}, \ \forall x \in \square.
\]

Then, by Lemma 2.1, \( g \in \mathcal{S}_\beta \), and by routine calculations, we get

\[
g(x) = h(x) - f(x) + f(x) + \frac{\epsilon}{2} \geq -\|f - h\|_\infty + f(x) + \frac{\epsilon}{2} > f(x) \geq 0.
\]
Furthermore, one has

$$\|f - g\|_\infty \leq \|f - h\|_\infty + \|h - g\|_\infty < \epsilon.$$ 

Thus, the proof of the theorem is complete.

\[\square\]

**Theorem 2.8** Let \( f : \square \to \mathbb{R} \) be a \((m, n)\)-convex function such that \( f(a, y) = f(x, c) = 0, \forall x \in I, y \in J. \) Then for \( \epsilon > 0, \) there exists \((m, n)\)-convex function \( g \) such that \( D^{(m,n)}g \in S_\beta \) and \( \|f - g\|_\infty < \epsilon. \)

**Proof** Let \( \epsilon > 0. \) Using Theorem 2.3, there exists \( h \in S_\beta \) such that \( \|D^{(m.n)}f - h\| < \frac{\epsilon}{(b-a)^m(d-c)^n}. \) By choosing

\[g(x, y) := \int_a^x \int_c^y \ldots \int_a^{x_{m-1}} \int_c^{y_{n-1}} h(x_m, y_n)dx_mdy_n \ldots dx_1dy_1,\]

we have

\[\|f - g\| = \sup_{(x, y) \in \square} \left\{ \left| f - \int_a^x \int_c^y \ldots \int_a^{x_{m-1}} \int_c^{y_{n-1}} h(x_m, y_n)dx_mdy_n \ldots dx_1dy_1 \right| \right\} < \epsilon,

proving the assertion.

\[\square\]

**Theorem 2.9** Let \( f \in C(\square). \) Then, for \( \epsilon > 0 \) there exists \( g \in S_\beta \) such that

\[g(x) \leq f(x) \forall x \in \square \text{ and } \|f - g\|_\infty < \epsilon.\]

**Proof** Since \( f \in C(\square) \) and \( \epsilon > 0, \) Theorem 2.3 generates a member \( h \in S_\beta \) such that

\[\|f - h\|_\infty < \frac{\epsilon}{2}.

Choose \( g(x) := h(x) - \frac{\epsilon}{2}, \forall x \in \square. \) Then,

\[g(x) = h(x) - f(x) + f(x) - \frac{\epsilon}{2} \leq \|f - h\|_\infty + f(x) - \frac{\epsilon}{2} < f(x).

Furthermore,

\[\|f - g\|_\infty \leq \|f - h\|_\infty + \|h - g\|_\infty < \epsilon,

establishing the proof.

\[\square\]
Now, we aim to show the existence of best one-sided approximation. Let \( \beta \in [2, 3] \), and define
\[
C_\beta(\square) := \{ f \in C(\square) : \overline{\dim}_B(Gr(f)) \leq \beta \}.
\]

In view of [10, Proposition 3.4], recall that \( C_\beta(\square) \) is a normed linear space. Let \( \{g_1, g_2, \ldots, g_n\} \) be a linearly independent subset of \( C_\beta(\square) \). Further, for a bounded below and Lebesgue integrable function \( f : \square \to \mathbb{R} \), we define
\[
\mathcal{Y}_n^\beta(f) := \left\{ h \in \text{span}\{g_1, g_2, \ldots, g_n\} : h(x) \leq f(x) \, \forall \, x \in \square \right\}.
\]

It is patent that the set \( \mathcal{Y}_n^\beta(f) \) is non-empty because \( f \) is bounded below. A function \( h_f \in \mathcal{Y}_n^\beta(f) \) is said to be a best one-sided approximation from below to \( f \) on \( \square \) if
\[
\int_\square h_f(x) \, dx = \sup \left\{ \int_\square h(x) \, dx : h \in \mathcal{Y}_n^\beta(f) \right\},
\]
where \( \int_\square g(x) \, dx = \int_a^b \int_c^d g(x) \, dx \). In a similar way, we define best one-sided approximations from above. We state the next theorem for one-sided approximation from below. Though a similar result can be proved in terms of one-sided approximation from above, see, for instance, [7, 24].

**Theorem 2.10** For a bounded below and integrable function \( f : \square \to \mathbb{R} \), there exists a member in \( \mathcal{Y}_n^\beta(f) \) of best one-sided approximant from below to \( f \) on \( \square \).

**Proof** Let \( (h_m) \) be a sequence in \( \mathcal{Y}_n^\beta(f) \) such that
\[
\int_\square h_m(x) \, dx \to A \quad \text{as} \quad m \to \infty, \quad (2.2)
\]
where \( A = \sup \left\{ \int_\square h(x) \, dx : h \in \mathcal{Y}_n^\beta(f) \right\} \). With an appropriate constant \( M_* > 0 \), we have
\[
\int_\square |h_m(x)| \, dx \leq \int_\square \left| h_m(x) - \frac{A}{(b-a)(d-c)} \right| \, dx
\]
\[
+ \int_\square \frac{A}{(b-a)(d-c)} \, dx \leq M_*.
\]

Let us recall a well-known fact that a closed and bounded subset of a normed linear space is compact if and only if it is finite-dimensional space. Since \( \mathcal{Y}_n^\beta(f) \) is a subset of finite-dimensional linear space, it follows that every closed ball of radius \( M_* \) in \( \mathcal{Y}_n^\beta(f) \) will be compact. Therefore, using the above inequality, there exist a subsequence \( (h_{m_k}) \) and a function \( h \in \mathcal{Y}_n^\beta(f) \) such that the sequence \( (h_{m_k}) \) converges to \( h \) in \( L^1(\square) \). Recall a basic functional analysis result that every norm is equivalent on a finite-dimensional linear space. Now, from the finite-dimensionality of \( \mathcal{Y}_n^\beta(f) \), it follows that the sequence
(h_{mk}) also converges to h uniformly. Further, since h_{m}(x) \leq f(x), \forall x \in \Box, and \ h_{mk} \to h \ uniformly, we get h(x) \leq f(x), \ \forall x \in \Box. Thus, h \in \mathcal{Y}_{n}^{\beta}(f). Now, by (2.2), we have

\[
\int_{\Box} h(x) \, dx = \lim_{k \to \infty} \int_{\Box} h_{mk}(x) \, dx = A,
\]

completing the task.  

\[ \square \]

2.1 Construction of dimension preserving approximants

First, Hutchinson [14] hinted at the generation of parameterized fractal curves. In [2], Barnsley introduced Fractal Interpolation Functions (FIFs) via Iterated Function System (IFS). We refer the reader to Barnsley [2] for more study regarding the construction of FIFs.

Computation of dimensions of fractal functions has been an integral part of fractal geometry. In [2], Barnsley proved estimates for the Hausdorff dimension of an affine FIF. Falconer also established a similar result in [8]. Barnsley and his collaborators [3, 4, 12] computed the box dimension of classes of affine FIFs. In [4], FIFs generated by bilinear maps have been studied. In [13], a formula for the box dimension of FIFs \( \mathbb{R}^{n} \to \mathbb{R}^{m} \) was proved. A particular case of FIFs given by Navascués [17], namely, (univariate) \( \alpha \)-fractal function has been proven very useful in approximation theory and operator theory. Using series expansion, the box dimension of (univariate) \( \alpha \)-fractal function is estimated in [25].

Let us recall a construction of bivariate \( \alpha \)-fractal function introduced in [23], which was influenced by Ruan and Xu [19], on rectangular grids.

Let \( x_{0} = a, \ x_{N} = b, \ y_{0} = c, \ y_{M} = d, \) and \( f \in \mathcal{C}(\Box) \). Let us denote \( \Sigma_{k} = \{1, 2, \ldots, k\}, \ \Sigma_{k,0} = \{0, 1, \ldots, k\}, \ \partial \Sigma_{k,0} = \{0, k\} \) and int\( \Sigma_{k,0} = \{1, 2, \ldots, k-1\} \). Further, a net \( \Delta \) on \( \Box \) is defined as follows:

\[
\Delta := \{ (x_{i}, y_{j}) : i \in \Sigma_{N,0}, \ j \in \Sigma_{M,0} \text{ and } x_{0} < x_{1} < \cdots < x_{N}; \ y_{0} < y_{1} < \cdots < y_{M} \}.
\]

For each \( i \in \Sigma_{N} \) and \( j \in \Sigma_{M} \), let us define \( I_{i} = [x_{i-1}, x_{i}] \), \( J_{j} = [y_{j-1}, y_{j}] \) and \( \Box_{ij} := I_{i} \times J_{j} \). Let \( i \in \Sigma_{N} \), we define contraction mappings \( u_{i} : I_{i} \to I_{i} \) such that

- \( u_{i}(x_{0}) = x_{i-1}, \ u_{i}(x_{N}) = x_{i}, \) if \( i \) is odd, and \( u_{i}(x_{0}) = x_{i}, \ u_{i}(x_{N}) = x_{i-1}, \) if \( i \) is even.

Similar to the above, for each \( j \in \Sigma_{M} \), we define \( v_{j} : J_{j} \to J_{j} \), and \( Q_{ij}(x) := (u_{i}^{-1}(x), v_{j}^{-1}(y)) \), where \( x = (x, y) \in \Box_{ij} \).

Let \( \alpha \in \mathcal{C}(\Box) \) such that \( \|\alpha\|_{\infty} < 1 \). Assume further that \( s \in \mathcal{C}(\Box) \) satisfying \( s(x_{i}, y_{j}) = f(x_{i}, y_{j}) \), for all \( i \in \partial \Sigma_{N,0}, \ j \in \partial \Sigma_{M,0} \). By [24, Theorem 3.4], we have
a unique function \( f_{\Delta, s}^{\alpha} \in C(\Box) \) termed as \( \alpha \)-fractal function, such that
\[
f_{\Delta, s}^{\alpha}(x) = f(x) + \alpha(x) f_{\Delta, s}^{\alpha}(Q_{ij}(x)) - \alpha(x) s(Q_{ij}(x)),
\]
for \( x \in \Box_{ij}, \ (i, j) \in \Sigma_N \times \Sigma_M \).

**Note 2.11** In this note, we recall Theorem 5.16 in [24]. With the metric
\[
d(\Box, y) := \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}, \quad \text{where } x = (x_1, x_2), \ y = (y_1, y_2),
\]
we consider \( f \) and \( s \) such that
\[
|f(x) - f(y)| \leq K_f d(\Box, y)^\sigma, \\
|s(x) - s(y)| \leq K_s d(\Box, y)^\sigma.
\]
(2.3)
for every \( x, y \in \Box \), and for fixed \( K_f, K_s > 0 \), and for fixed \( 0 < \sigma \leq 1 \). Assume that for some \( k_f > 0 \), \( \delta_0 > 0 \) the following holds: for each \( x \in \Box \) and \( 0 < \delta < \delta_0 \) there exists \( y \) such that \( d(\Box, y) \leq \delta \) and
\[
|f(x) - f(y)| \geq k_f d(\Box, y)^\sigma.
\]
(2.4)
Furthermore, we suppose \( N = M, \ x_i - x_{i-1} = \frac{1}{N}, \ y_j - y_{j-1} = \frac{1}{M}, \forall i \in \Sigma_N, \ j \in \Sigma_M \) and constant scaling function \( \alpha \).

If \( |\alpha| < \min \left\{ \frac{1}{M}, \left( \frac{k_f}{K_f + K_s} \right)^{\frac{1}{\sigma}} \right\} \), then \( \dim_B(\text{Gr}(f_{\Delta, s}^{\alpha})) = 3 - \sigma \).

**Remark 2.12** With the assumptions in the above note, one may construct dimension preserving approximants for a given function, see, for instance, [22, Theorem 3.16].

Navascués [18] developed the notion of (univariate) \( \alpha \)-fractal function via so-called (univariate) fractal operator. In [23, 24], her collaborators extended some of her results in a bivariate setting. On putting \( L = B_{m,n} \) in [23, Theorem 3.1], we have a unique function \( f_{\Delta, B_{m,n}}^{\alpha} \in C(\Box) \) such that
\[
f_{\Delta, B_{m,n}}^{\alpha}(x) = f(x) + \alpha(x) f_{\Delta, B_{m,n}}^{\alpha}(Q_{ij}(x)) - \alpha(x) B_{m,n}(f)(Q_{ij}(x)),
\]
(2.5)
for \( x \in \Box_{ij}, \ (i, j) \in \Sigma_N \times \Sigma_M \).

Following the work of [23], we define a single-valued fractal operator \( F_{m,n}^{\alpha} : C(\Box) \rightarrow C(\Box) \) by
\[
F_{m,n}^{\alpha}(f) = f_{\Delta, B_{m,n}}^{\alpha}.
\]
In [23], several operator theoretic results for fractal operator are obtained. We recall that \( F_{m,n}^{\alpha} \) is a bounded linear operator, see, for instance, [23, Theorem 3.2].
Lemma 2.13 ([5], Lemma 1) Let \((X, \|\cdot\|)\) be a Banach space, \(T : X \to X\) be a linear operator. Suppose there exist constants \(\lambda_1, \lambda_2 \in [0, 1)\) such that

\[
\|Tx - x\| \leq \lambda_1 \|x\| + \lambda_2 \|Tx\|, \quad \forall \ x \in X.
\]

Then \(T\) is a topological isomorphism, and

\[
\frac{1 - \lambda_2}{1 + \lambda_1} \|x\| \leq \|T^{-1}x\| \leq \frac{1 + \lambda_2}{1 - \lambda_1} \|x\|, \quad \forall \ x \in X.
\]

Note 2.14 We have the following.

\[
B_{m,n}(f)(x) = \frac{1}{(b-a)^m(d-c)^n} \sum_{i=0}^{m} \sum_{j=0}^{n} \binom{m}{i} \binom{n}{j} (x-a)^i (b-x)^{m-i} (y-c)^j (d-y)^{n-j} f\left(a + \frac{i(b-a)}{m}, c + \frac{j(d-c)}{n}\right).
\]

Choosing \(f = 1\), we have

\[
B_{m,n}1(x) = \frac{1}{(b-a)^m(d-c)^n} \sum_{i=0}^{m} \sum_{j=0}^{n} \binom{m}{i} \binom{n}{j} (x-a)^i (b-x)^{m-i} (y-c)^j (d-y)^{n-j}
\]

\[
= \frac{1}{(b-a)^m(d-c)^n} \sum_{i=0}^{m} \binom{m}{i} (x-a)^i (b-x)^{m-i}
\]

\[
\sum_{j=0}^{n} \binom{n}{j} (y-c)^j (d-y)^{n-j}
\]

\[
= \frac{1}{(b-a)^m(d-c)^n} \sum_{i=0}^{m} \binom{m}{i} (x-a)^i (b-x)^{m-i} (y-c + d - y)^n
\]

\[
= \frac{1}{(b-a)^m(d-c)^n} (x-a+b-x)^m (y-c+d-y)^n
\]

\[
= 1.
\]
This implies that \( \|B_{m,n}\| \geq 1 \). Now, for every \( f \in C(\square) \) we get

\[
|B_{m,n}(f)(x)| \leq \frac{\|f\|_{\infty}}{(b-a)^m(d-c)^n} \sum_{i=0}^{m} \sum_{j=0}^{n} \binom{m}{i} \binom{n}{j} (x-a)^i (b-x)^{m-i} (y-c)^j (d-y)^{n-j} = \|f\|_{\infty},
\]

which produces \( \|B_{m,n}\| \leq 1 \). Therefore, we have \( \|B_{m,n}\| = 1 \).

**Theorem 2.15** The fractal operator \( F_{m,n}^{\alpha} : C(\square) \to C(\square) \) is a topological isomorphism.

**Proof** Using equation (2.5) and note 2.14, one gets

\[
\|f - F_{m,n}^{\alpha}(f)\|_{\infty} \leq \|\alpha\|_{\infty} \|F_{m,n}^{\alpha}(f) - B_{m,n}f\|_{\infty} \leq \|\alpha\|_{\infty} \|F_{m,n}^{\alpha}(f)\|_{\infty} + \|\alpha\|_{\infty} \|f\|_{\infty}.
\]

Since \( \|\alpha\|_{\infty} < 1 \), the previous lemma yields that the fractal operator \( F_{m,n}^{\alpha} \) is a topological isomorphism. \( \square \)

**Remark 2.16** The above theorem may strengthen item-4 of [23, Theorem 3.2]. To be precise, item-4 tells that \( F_{m,n}^{\alpha} \) is a topological isomorphism if \( \|\alpha\|_{\infty} < (1 + \|I - B_{m,n}\|)^{-1} \), which is more restricted than the standing assumption considered in the above theorem, that is, \( \|\alpha\|_{\infty} < 1 \).

**Theorem 2.17** Let \( f \in C(\square) \) be such that \( f(x) \geq 0 \), \( \forall x \in \square \). Then for \( \epsilon > 0 \), \( \beta \in [2,3] \), and for \( \alpha \in C(\square) \) satisfying \( \|\alpha\|_{\infty} < 1 \), we have an \( \alpha \)-fractal function \( g_{\alpha,B_{m,n}}^{\beta} \) satisfying

\[
g_{\alpha,B_{m,n}}^{\beta}(x) \geq 0, \quad \forall x \in \square \text{ and } \|f - g_{\alpha,B_{m,n}}^{\beta}\|_{\infty} < \epsilon.
\]

**Proof** Note that the Bernstein operator \( B_{m,n} \) fixes the constant function 1, that is, \( B_{m,n}(1) = 1 \), where \( 1(x) = 1 \) on \( \square \). Consider \( \alpha \in C(\square) \) such that \( \|\alpha\|_{\infty} < 1 \). From Equation 2.5, we deduce

\[
\|g_{\alpha,B_{m,n}}^{\beta} - g\|_{\infty} \leq \|\alpha\|_{\infty} \|g_{\alpha,B_{m,n}}^{\beta} - B_{m,n}g\|_{\infty}, \quad \forall g \in C(\square).
\]

Choose \( g = 1 \), then the above inequality gives

\[
\|1_{\alpha,B_{m,n}} - 1\|_{\infty} \leq \|\alpha\|_{\infty} \|1_{\alpha,B_{m,n}} - 1\|_{\infty},
\]

and this further yields \( \|1_{\alpha,B_{m,n}} - 1\|_{\infty} = 0 \). Therefore, \( 1_{\alpha,B_{m,n}} = 1 \), that is, \( F_{m,n}^{\alpha}(1) = 1 \).
Let \( f \in C(\square) \) such that \( f(x) \geq 0 \), and let \( \beta \in [2, 3] \). Then, for each \( \epsilon > 0 \), using Theorem 2.3 and Theorem 2.15, there exists a function \( h_{\Delta,B_{m,n}}^{\alpha} \in S_\beta \) such that

\[
\| f - h_{\Delta,B_{m,n}}^{\alpha} \|_\infty < \frac{\epsilon}{2}, \text{ where } \mathcal{F}_{m,n}^{\alpha}(h) = h_{\Delta,B_{m,n}}^{\alpha}.
\]

Define \( g_{\Delta,B_{m,n}}^{\alpha}(x) = h_{\Delta,B_{m,n}}^{\alpha}(x) + \frac{\epsilon}{2} \) for all \( x \in \square \). Since \( \mathcal{F}_{m,n}^{\alpha}(1) = 1 \),

\[
g_{\Delta,B_{m,n}}^{\alpha}(x) = h_{\Delta,B_{m,n}}^{\alpha}(x) + \frac{\epsilon}{2} 1(x) = h_{\Delta,B_{m,n}}^{\alpha}(x) + \frac{\epsilon}{2} 1^{\alpha}(x).
\]

Further, since \( \mathcal{F}_{m,n}^{\alpha} \) is a linear operator

\[
g_{\Delta,B_{m,n}}^{\alpha} = h_{\Delta,B_{m,n}}^{\alpha} + \frac{\epsilon}{2} 1^{\alpha} = \mathcal{F}_{m,n}^{\alpha}(h + \frac{\epsilon}{2} 1).
\]

Moreover,

\[
g_{\Delta,B_{m,n}}^{\alpha}(x) = h_{\Delta,B_{m,n}}^{\alpha}(x) + \frac{\epsilon}{2} = h_{\Delta,B_{m,n}}^{\alpha}(x) + \frac{\epsilon}{2} - f(x) + f(x) \\
\geq f(x) + \frac{\epsilon}{2} - \| h_{\Delta,B_{m,n}}^{\alpha} - f \|_\infty \\
\geq 0.
\]

Further, we get

\[
\| f - g_{\Delta,B_{m,n}}^{\alpha} \|_\infty \leq \| f - h_{\Delta,B_{m,n}}^{\alpha} \|_\infty + \| h_{\Delta,B_{m,n}}^{\alpha} - g_{\Delta,B_{m,n}}^{\alpha} \|_\infty \\
< \frac{\epsilon}{2} + \frac{\epsilon}{2} \\
= \epsilon,
\]

completing the proof.

\( \square \)

### 3 Some multi-valued mappings

First, we collect some definitions and related results which will be used in this section.

**Definition 3.1** ([1]). Let \( (X, \| \cdot \|_X) \) and \( (Y, \| \cdot \|_Y) \) be normed linear spaces. For a multi-valued (set-valued) mapping \( T : X \rightrightarrows Y \), the domain of \( T \) is defined by \( \text{Dom}(T) := \{ x \in X : T(x) \neq \emptyset \} \). Then \( T : X \rightrightarrows Y \) is

1. **convex** if

\[
\lambda T(x_1) + (1 - \lambda) T(x_2) \subseteq T(\lambda x_1 + (1 - \lambda) x_2), \quad \forall x_1, x_2 \in \text{Dom}(T), \; \lambda \in [0, 1].
\]
(2) \textit{process} if
\[ \lambda T(x) = T(\lambda x), \quad \forall x \in X, \quad \lambda > 0, \quad \text{and} \quad 0 \in T(0). \]

(3) \textit{linear} if
\[ \beta T(x_1) + \gamma T(x_2) \subseteq T(\beta x_1 + \gamma x_2), \quad \forall x_1, x_2 \in \text{Dom}(T), \quad \beta, \gamma \in \mathbb{R}. \]

(4) \textit{closed} if the graph of \( T \) defined by \( Gr(T) := \{(x) \in X \times Y : y \in T(x)\} \) is closed.

(5) \textit{Lipschitz} if
\[ T(x_1) \subseteq T(x_2) + l\|x_1 - x_2\|_X U_Y, \quad \forall x_1, x_2 \in \text{Dom}(T), \text{ for some constant } l > 0, \]
where \( U_Y = \{y \in Y : \|y\|_Y \leq 1\}. \)

(6) \textit{lower semicontinuous} at \( x \in X \) if there exists a \( \delta > 0 \) such that
\[ U \cap T(x') \neq \emptyset \quad \text{whenever} \quad \|x - x'\|_X < \delta \]
holds for a given open set \( U \) in \( Y \) satisfying \( U \cap T(x) \neq \emptyset \).

Note that the above definitions are also applicable in metric spaces with obvious modifications, see, for instance, [1].

**Theorem 3.2** ([6], Corollary 1.4) \textit{Let } \( T : \text{Dom}(T) = X \rightrightarrows Y \text{ be linear such that } T(0) = \{0\}. \text{ Then, } T \text{ is single-valued.} \}

**Theorem 3.3** ([6], Corollary 2.1) \textit{Let } \( T : \text{Dom}(T) = X \rightrightarrows Y \text{ be such that } T(x_0) \text{ is singleton for some } x_0 \in X. \text{ Then the following are equivalent: } \)

- \( T \) is single-valued and affine.
- \( T \) is convex.

Our work in this part is partly motivated by [25].

**Theorem 3.4** \textit{The multi-valued mapping } \( \mathcal{W}^{\alpha}_\Delta : \mathcal{C}(\square) \rightrightarrows \mathcal{C}(\square) \text{ defined by } \)
\[ \mathcal{W}^{\alpha}_\Delta(f) = \{f^{\alpha}_{\Delta,B_{m,n}} : m, n \in \mathbb{N}\} \]
\textit{is a Lipschitz process.}

**Proof** Using the linearity of \( \mathcal{F}^{\alpha}_{m,n} \), we have
\[ \mathcal{W}^{\alpha}_\Delta(\lambda f) = \{(\lambda f)^{\alpha}_{\Delta,B_{m,n}} : m, n \in \mathbb{N}\} = \lambda \mathcal{W}^{\alpha}_\Delta(f), \quad \forall f \in \mathcal{C}(\square), \quad \lambda > 0. \]
Again by linearity of \( \mathcal{F}^{\alpha}_{m,n} \), it is plain that \( \mathcal{W}^{\alpha}_\Delta(0) = \{0\} \). Therefore, \( \mathcal{W}^{\alpha}_\Delta \) is a process.

\(\square\) Springer
Let $f, g \in C(\Box)$. On applying Equation 2.5, we have

$$\left| f_{\alpha, B_m,n}^\Delta(x) - g_{\alpha, B_m,n}^\Delta(x) \right| \leq \| f - g \|_\infty + \| \alpha \|_\infty \| f_{\alpha, B_m,n}^\Delta - g_{\alpha, B_m,n}^\Delta \|_\infty$$

for any $x \in \Box$. Further, we deduce

$$\| f_{\alpha, B_m,n}^\Delta - g_{\alpha, B_m,n}^\Delta \|_\infty \leq \frac{1 + \| \alpha \|_\infty \| B_m,n(g) - B_m,n(f) \|_\infty}{1 - \| \alpha \|_\infty} \| f - g \|_\infty.$$  

Using $\| B_m,n \| = 1,$

$$\| f_{\alpha, B_m,n}^\Delta - g_{\alpha, B_m,n}^\Delta \|_\infty \leq \frac{1 + \| \alpha \|_\infty \| B_m,n \|}{1 - \| \alpha \|_\infty} \| f - g \|_\infty.$$

Consequently, we have

$$W_{\alpha/\Delta}^\Delta(g) \subseteq W_{\alpha/\Delta}^\Delta(f) + \frac{1 + \| \alpha \|_\infty \| B_m,n \|}{1 - \| \alpha \|_\infty} \| f - g \|_\infty U_C(\Box),$$

proving the Lipschitz property of $W_{\alpha/\Delta}^\Delta$, and hence, we complete the proof. 

**Remark 3.5** For the multivalued mapping $W_{\alpha/\Delta}^\Delta$, let us first note the following:

1. By linearity of $F_{\alpha, m,n}^\Delta$, we have $W_{\alpha/\Delta}^\Delta(0) = \{0\}$.
2. Since if $\alpha \neq 0, m \neq k$ then $f_{\alpha, B_m,n}^\Delta \neq f_{\alpha, B_k,l}^\Delta$, hence $W_{\alpha/\Delta}^\Delta : C(\Box) \Rightarrow C(\Box)$ is not single-valued.

In view of the above items, Theorems 3.2-3.3 produce that the mapping $W_{\alpha/\Delta}^\Delta : C(\Box) \Rightarrow C(\Box)$ is not convex.

**Theorem 3.6** Let $\triangle$ be a fixed net and $m, n \in \mathbb{N}$. Then, the multivalued mapping $T_{m,n}^\Delta : C(\Box) \Rightarrow C(\Box)$ defined by

$$T_{m,n}^\Delta(f) = \{ f_{\alpha, B_m,n}^\Delta : \alpha \in C(\Box) \text{ such that } \| \alpha \|_\infty < 1 \}$$

is a process and lower semicontinuous.

**Proof** Let $f \in C(\Box)$ and $\lambda > 0$,

$$\lambda T_{m,n}^\Delta(f) = \lambda \{ f_{\alpha, B_m,n}^\Delta : \alpha \in C(\Box) \text{ such that } \| \alpha \|_\infty < 1 \}$$

$$= \{ \lambda f_{\alpha, B_m,n}^\Delta : \alpha \in C(\Box) \text{ such that } \| \alpha \|_\infty < 1 \}$$

$$= T_{m,n}^\Delta(\lambda f).$$

Moreover, Using linearity of fractal operator, we have $f_{\alpha, B_m,n}^\Delta = 0$, whenever $f = 0$. That is, $0 \in T_{m,n}^\Delta(0)$. Therefore, $T_{m,n}^\Delta$ is a process. Now, it remains to show that $T_{m,n}^\Delta$ is lower semicontinuous.
is lower semicontinuous. For this, let \( f \in \mathcal{C}(\square) \), \( f^\alpha_{\Delta, B_{m,n}} \in T^\Delta_{m,n}(f) \) and a sequence \( (f_k) \) in \( \mathcal{C}(\square) \) such that \( f_k \to f \). Since the fractal operator is continuous, we have \( (f^\alpha_{\Delta, B_{m,n}})_{k} \to f^\alpha_{\Delta, B_{m,n}} \). It is clear that \( (f^\alpha_{\Delta, B_{m,n}})_{k} \in T^\Delta_{m,n}(f_k) \). Therefore, the result follows. \( \square \)

**Remark 3.7** One may see that \( T^\Delta_{m,n} \) is not convex through the following lines. Let \( f, g \in \mathcal{C}(\square) \),

\[
T^\Delta_{m,n}(f + g) = \{ (f + g)^\alpha_{\Delta, B_{m,n}} : \alpha \in \mathcal{C}(\square) \text{ such that } ||\alpha||_\infty < 1 \}
\]

\[
\subseteq \{ f^\alpha_{\Delta, B_{m,n}} + g^\alpha_{\Delta, B_{m,n}} : \alpha \in \mathcal{C}(\square) \text{ such that } ||\alpha||_\infty < 1 \}
\]

\[
\subseteq \{ f^\alpha_{\Delta, B_{m,n}} + g^\beta_{\Delta, B_{m,n}} : \alpha, \beta \in \mathcal{C}(\square) \text{ such that } ||\alpha||_\infty < 1, ||\beta||_\infty < 1 \}
\]

\[
\subseteq T^\Delta_{m,n}(f) + T^\Delta_{m,n}(g).
\]

**Theorem 3.8** Let \( \Delta \) be a fixed net and \( m, n \in \mathbb{N} \). Then, the multivalued mapping \( T^\Delta_{m,n} : \mathcal{C}(\square) \to \mathcal{C}(\square) \) defined by

\[
T^\Delta_{m,n}(f) = \{ f^\alpha_{\Delta, B_{m,n}} : ||\alpha||_\infty \leq q < 1 \},
\]

is Lipschitz with Lipschitz constant \( l = \frac{1 + q}{1 - q} \), and satisfies the following:

\[
||T^\Delta_{m,n}|| \leq 1 + \frac{q}{1 - q} ||Id - B_{m,n}||.
\]

**Proof** Let \( f, g \in \mathcal{C}(\square) \). Equation (2.5) yields

\[
||f^\alpha_{\Delta, B_{m,n}}(x) - g^\alpha_{\Delta, B_{m,n}}(x)|| = ||f - g||_\infty + ||\alpha||_\infty ||f^\alpha_{\Delta, B_{m,n}} - g^\alpha_{\Delta, B_{m,n}}||_\infty
\]

\[
+ ||\alpha||_\infty ||B_{m,n}g - B_{m,n}f||_\infty,
\]

for every \( x \in \square \). Further, we deduce

\[
||f^\alpha_{\Delta, B_{m,n}} - g^\alpha_{\Delta, B_{m,n}}|| \leq \frac{1 + ||\alpha||_\infty ||B_{m,n}||}{1 - ||\alpha||_\infty} ||f - g||_\infty.
\]

Since \( ||\alpha||_\infty \leq q \) and \( ||B_{m,n}|| = 1 \), we get

\[
||f^\alpha_{\Delta, B_{m,n}} - g^\alpha_{\Delta, B_{m,n}}|| \leq \frac{1 + q}{1 - q} ||f - g||_\infty.
\]

Choosing \( l = \frac{1 + q}{1 - q} \), we have

\[
T^\Delta_{m,n}(g) \subseteq T^\Delta_{m,n}(f) + l ||f - g||_\infty U_{\mathcal{C}(\square)},
\]
proving one part of the theorem. For other part, we have

\[
\| T_{\Delta m, n} \| = \sup_{f \in C(\square)} \frac{d(0, T_{\Delta m, n}(f))}{\| f \|_{\infty}}
\]

\[
= \sup_{f \in C(\square)} \inf_{f_{\Delta, B_{m, n}} \in T_{\Delta m, n}(f)} \frac{\| f_{\Delta, B_{m, n}} \|}{\| f \|}
\]

\[
\leq \sup_{f \in C(\square)} \left( 1 + \frac{\| \alpha \|_{\infty}}{1 - \| \alpha \|_{\infty}} \| Id - B_{m, n} \| \right)
\]

\[
\leq \sup_{f \in C(\square)} \left( 1 + \frac{q}{1 - q} \| Id - B_{m, n} \| \right)
\]

\[
= 1 + \frac{q}{1 - q} \| Id - B_{m, n} \|,
\]

completing the proof. \(\square\)

**Theorem 3.9** For a fixed admissible scale vector \(\alpha\) and \(m, n \in \mathbb{N}\), the multivalued mapping \(\mathcal{V}_{m, n}^{\alpha} : C(\square) \rightharpoonup C(\square)\) defined by

\[
\mathcal{V}_{m, n}^{\alpha}(f) = \{ f_{\Delta, B_{m, n}}^{\alpha} : \text{all possible net } \Delta \}
\]

is a process and lower semicontinuous.

**Proof** Let \(f \in C(\square)\) and \(\lambda > 0\), then

\[
\lambda \mathcal{V}_{m, n}^{\alpha}(f) = \lambda \{ f_{\Delta, B_{m, n}}^{\alpha} : \text{all possible net } \Delta \}
\]

\[
= \{ \lambda f_{\Delta, B_{m, n}}^{\alpha} : \text{all possible net } \Delta \}
\]

\[
= \{ (\lambda f)^{\alpha}_{\Delta, B_{m, n}} : \text{all possible net } \Delta \}
\]

\[
= \mathcal{V}_{m, n}^{\alpha}(\lambda f).
\]

The third equality follows from the fact that the fractal operator \(\mathcal{F}_{\Delta m, n}^{\alpha}\) is a linear operator. Moreover, using linearity of the fractal operator, we have \(f_{\Delta, B_{m, n}}^{\alpha} = 0\), whenever \(f = 0\). That is, \(0 \in \mathcal{V}_{m, n}^{\alpha}(0)\). Therefore, \(\mathcal{V}_{m, n}^{\alpha}\) is a process. Now, for the lower semicontinuity of \(\mathcal{V}_{m, n}^{\alpha}\), let \(f \in C(\square)\), \(f_{\Delta, B_{m, n}}^{\alpha} \in \mathcal{V}_{m, n}^{\alpha}(f)\) and a sequence \((f_k)\) converges to \(f\) in \(C(\square)\). Since the fractal operator is continuous, we have \((f_k)_{\Delta, B_{m, n}}^{\alpha} \to f_{\Delta, B_{m, n}}^{\alpha}\). By definition of \(\mathcal{V}_{m, n}^{\alpha}\), \((f_k)_{\Delta, B_{m, n}}^{\alpha}\) \(\in \mathcal{V}_{m, n}^{\alpha}(f_k)\). Hence, the lower semicontinuity of \(\mathcal{V}_{m, n}^{\alpha}\) follows. \(\square\)

**Theorem 3.10** The multi-valued function \(\Phi : [\dim(X), \dim(X) + \dim(Y)] \to C(X, Y)\) defined by

\[
\Phi(\beta) := \{ f \in C(X, Y) : \dim(Gr(f)) = \beta \}
\]

is lower semicontinuous.
Proof Let $U$ be an open set of $C(X, Y)$. In the light of Theorem 2.3, that is, $\Phi(\alpha) = S_\alpha$ is a dense subset of $C(X, Y)$, we obtain

$$S(\alpha) \cap U \neq \emptyset, \forall \alpha \in [\dim(X), \dim(X) + \dim(Y)].$$

Now, by the very definition of lower semicontinuous, the result follows. $\square$

Remark 3.11 Note that the multivalued mapping $\Phi$ is not closed. To show this, let $f \in C(X, Y)$ with $\dim(Gr(f)) > \dim(X)$. Consider a sequence of Lipschitz functions $(f_k)$ converging to $f$ uniformly. It is obvious that $\dim(Gr(f_k)) = \dim(X)$. Now, we have $(\dim(X), f_k) \to (\dim(X), f)$ as $n \to \infty$. Using $(\dim(X), f_k) \in Gr(\Phi)$ and $(\dim(X), f_k) \to (\dim(X), f)$ with $\dim(Gr(f)) > \dim(X)$, we get the result.

4 Conclusion

This paper has been intended to develop a newly defined notion of constrained approximation termed as dimension preserving approximation for bivariate functions. The later work of the paper has introduced some multi-valued operators associated with bivariate $\alpha$-fractal functions. The notion of dimension preserving approximation is new, and demands further developments. In particular, dimension preserving approximation of set-valued mappings may be one of our future investigations.
