Abstract

A permutation $\pi$ avoids the simsun pattern $\tau$ if $\pi$ avoids the consecutive pattern $\tau$ and the same condition applies to the restriction of $\pi$ to any interval $[k]$. Permutations avoiding the simsun pattern 321 are the usual simsun permutation introduced by Simion and Sundaram. Deutsch and Elizalde enumerated the set of simsun permutations that avoid in addition any set of patterns of length 3 in the classical sense. In this paper we enumerate the set of permutations avoiding any other simsun pattern of length 3 together with any set of classical patterns of length 3. The main tool in the proofs is a massive use of a bijection between permutations and increasing binary trees.

Mathematics Subject Classifications: 05A05, 05A15, 05C05

1 Introduction

A permutation $\sigma \in S_n$ avoids the (classical) pattern $\tau \in S_k$ if there are no indices $i_1, i_2, \ldots, i_k$ such that the subsequence $\sigma_{i_1} \sigma_{i_2} \ldots \sigma_{i_k}$ is order isomorphic to $\tau$.

A permutation $\sigma$ is called simsun (after Rodica Simion and Sheila Sundaram) if it does not contain double descents and the same applies to the restriction of $\sigma$ to any interval $[k]$. For example, 41325 is simsun, while 32415 is not. The theory of simsun permutation goes back to the work by Sundaram [13] where the author proved that the cardinality of the set of simsun permutations of length $n$ is the $(n+1)$-th Euler number (see sequence A000111 in [11]). These permutations have been intensively studied in recent years (see e.g. [3, 4, 5, 7, 8, 9]).

In this paper, we deal with a generalization of simsun permutations defined by Lin, Ma, and Yeh ([7]): we say that a permutation $\sigma$ avoids the simsun pattern $\tau$ if the restriction of $\sigma$ to the interval $[k]$ does not contain the consecutive pattern $\tau$ for any $k = 1, \ldots, n$.
We denote by $S_n(\tau^S)$ the set of all permutations in $S_n$ that avoid the simsun pattern $\tau$. In particular, the set $S_n(321^S)$ is the set of Simsun permutations of length $n$. If $\Sigma \subseteq \cup_{i \geq 0} S_i$ is any set of permutations, we denote by $S_n(\tau^S, \Sigma)$ the set of permutations of length $n$ that avoid the simsun pattern $\tau$ and avoid every classical pattern in $\Sigma$. If $\Sigma$ contains the patterns $\sigma_1, \sigma_2, \ldots, \sigma_k$ we will write $S_n(\tau^S, \sigma_1, \sigma_2, \ldots, \sigma_k)$ instead of $S_n(\tau^S, \{\sigma_1, \sigma_2, \ldots, \sigma_k\})$.

Observe that, if the permutation $\pi$ is the image of $\rho$ under the usual reverse map and $\Sigma'$ is the set of permutations obtained by reversing all the permutations in $\Sigma$, we have $|S_n(\tau^S, \Sigma)| = |S_n(\rho^S, \Sigma')|$. Hence, for all $\Sigma$, we can partition the set of simsun patterns of length 3 into three classes with respect to the avoidance of the classical patterns in $\Sigma$:

$$|S_n(123^S, \Sigma)| = |S_n(321^S, \Sigma')|$$

$$|S_n(132^S, \Sigma)| = |S_n(231^S, \Sigma')|$$

$$|S_n(213^S, \Sigma)| = |S_n(312^S, \Sigma')|.$$ 

In [4] the authors enumerated $S_n(321^S, \Sigma)$ for all $\Sigma \subseteq S_3$. Moreover, it is well known (see [2] or [7]) that $|S_n(132^S)|$ is the $n$-th Bell number (sequence A000110 in [11]).

In the present paper we study the sets $S_n(132^S, \Sigma)$ and $S_n(213^S, \Sigma)$ for every $\Sigma \subseteq S_3$.

We find a recursive formula for the enumerating sequence of each of these sets, some of them appear on [11] with different interpretations, while the others are not present on that database. Our analysis is based on a systematic use of well-known bijection between permutations and binary increasing trees.

Notice that the avoidance of the simsun patterns $132^S$ and $213^S$ can be recast in terms of barred generalized patterns. In the last Section we describe this relationship.

## 2 Permutations avoiding the simsun pattern 132 and $\Sigma \subseteq S_3$

We observe that a permutation $\pi$ avoids the simsun pattern 132 if and only if each occurrence of 132 in $\pi$ is part of an occurrence of 2413 or, equivalently, $\pi$ avoids the barred pattern 2413. It has been shown in [2] that these permutations are enumerated by the Bell numbers. We will use the bijection $\psi$ between $S_n(132^S)$ and the set of partitions of $\{1, 2, \ldots, n\}$ presented in [7]. Write $\pi \in S_n(132^S)$ as $\pi = w_1w_2\ldots w_k$ where $w_i = x_{i,1}x_{i,2}\ldots x_{i,s_i}$ are the ascending runs of $\pi$. Then $\psi(\pi)$ is the partition of $n$ whose blocks are $\{x_{1,1}, \ldots, x_{1,s_1}\}, \ldots, \{x_{k,1}, \ldots, x_{k,s_k}\}$. Notice that the sequence $x_{1,1}, x_{2,1}, \ldots, x_{k,1}$ is decreasing, since $\pi$ avoids the simsun pattern 132. This ensures that the map $\phi$ is a bijection.

Let $\Sigma \subseteq S_3$ and let $\pi \in S_n(132^S, \Sigma)$. As noted above, each occurrence of 132 in $\pi$ is part of an occurrence of 2413. Since 2413 contains the patterns 132, 231, 312, 213, if $\Sigma$ contains at least one of those patterns, then

$$S_n(132^S, \Sigma) = S_n(132, \Sigma).$$

Hence, these cases can be traced back to classical pattern avoidance. See [10] for the complete classification and enumeration of the sets $S_n(\Sigma)$ with $\Sigma \subseteq S_3$. 

*THE ELECTRONIC JOURNAL OF COMBINATORICS 27(3) (2020), #P3.45*
Moreover if $\Sigma = \{123, 321\}$, the sets $S_n(132^S, \Sigma)$ are empty for $n \geq 7$.

Thus, the only remaining cases are $\Sigma = \{123\}$ and $\Sigma = \{321\}$.

2.1 $S_n(132^S, 123)$

Let $\pi \in S_n(132^S, 123)$. Since $\pi$ avoids the pattern 123, the ascending runs of $\pi$ have length at most two and the sequence of the greatest elements of each ascending run is decreasing, i.e., with the notation above, $x_{1,s_1} > x_{2,s_2} > \cdots > x_{k,s_k}$. Moreover, as seen above, $x_{1,1} > x_{2,1} > \cdots > x_{k,1}$.

Hence, the set $P_n$ corresponding to $S_n(132^S, 123)$ under the map $\psi$ consists of the partitions of $\{1, 2, \ldots, n\}$ such that

- every block has at most two elements and
- if the blocks are arranged in descending order of their smallest element, also the greatest elements of the blocks are in descending order.

There is a simple bijection between the set $P$ and the set of Motzkin paths of length $n$. We recall that a Motzkin path of length $n$ is a lattice path starting at $(0, 0)$, ending at $(n, 0)$, and never going below the $x$-axis, consisting of up steps $(1, 1)$, horizontal steps $(1, 0)$, and down steps $(1, -1)$.

More precisely, given a partition in $P$, we can construct the Motzkin path whose $i$-th step is

- a horizontal step, if the block containing $i$ has cardinality one,
- an up step, if the block containing $i$ has cardinality two and $i$ is the least element of its block,
- a down step, otherwise.

As a consequence, denoting by $M_n$ the $n$-th Motzkin number (sequence A001006 in [11]) we have

$$|S_n(132^S, 123)| = M_n.$$

2.2 $S_n(132^S, 321)$

If $\pi \in S_n(132^S, 321)$, then $\pi$ has at most two ascending runs, namely the partition $\psi(\pi)$ has at most two blocks. It is immediate to see that the number of such partitions is $2^{n-1}$, therefore

$$|S_n(132^S, 123)| = 2^{n-1}.$$
3 Permutations avoiding the simsun pattern 213

First of all we describe a well-known and widely used bijection \( \phi \) (see e.g. [6, p. 143] or [12, p. 44]) between the set \( W_n \) of words without repetitions of length \( n \) in \( \mathbb{Z}^+ \) and the set of binary increasing trees with \( n \) nodes. By definition, a binary increasing tree \( (\text{b.i.t.}) \) is a plane, rooted, binary tree in which each of the \( n \) nodes bears a different positive integer label and labels increase along any descending path. In the sequel we will often identify each node with its label. A non-empty maximal sequence of adjacent left edges of a b.i.t. will be called left branch. The definition of right branch is analogous.

The definition of the map \( \phi \) is as follows. The empty word is mapped to the empty tree. Consider now a word \( u \) in \( W_n \), \( n \geq 1 \). Denote by \( a \) the minimal integer appearing in \( u \) and write \( u \) as \( u = vaw \) where \( v \) and \( w \) are (possibly empty) words. Consider the trees \( t_1 = \phi(v) \) and \( t_2 = \phi(w) \). Define \( \phi(u) \) to be the tree

- whose root is labelled by \( a \),
- whose left subtree of the root is \( t_1 \) and
- whose right subtree of the root is \( t_2 \).

Needless to say, the image of \( S_n \) under the map \( \phi \) is the set \( T_n \) of binary increasing trees with labels from \( \{1, 2, \ldots, n\} \).

As an example consider \( \pi = 451326 \in S_6 \). Then

\[
\phi(\pi) = \begin{array}{c}
1 \\
4 \\
5 \\
3 \\
2 \\
6
\end{array}
\]

We now characterize the subset of \( T_n \) corresponding to \( S_n(213^S) \) under the map \( \phi \). We say that a b.i.t. is a \( \Delta \)-tree if it is a tree of the following form

\[
a
\quad b
\quad x
\quad c
\]

where \( a < b < c \), \( x \leq c \) and where the nodes labelled with \( x \) and \( c \) are connected by an arbitrarily long sequence of left edges.
Theorem 1. The map $\phi$ is a bijection between the set $S_n(213^S)$ and the set of b.i.t.'s that do not contain $\blacksquare$-subtrees.

Proof. Suppose that the tree $t$ contains a $\blacksquare$-subtree and let $\pi = \phi^{-1}(t)$. Then $\pi = uvwcr$ where $u, v, w, r$ are (possibly empty) words such that the symbols of $w$ are greater than the symbol $c$ and the symbols of $v$ are greater than the symbol $a$. If each symbol of $v$ is greater than $c$, then $\pi$ contains the simsun pattern $bac$. Otherwise, there exists a symbol of $v'$ of $v$ such that $v' < c$. In this case we can replace $b$ by $v'$, and $b'ac$ is an occurrence of the simsun pattern $213$.

Conversely, suppose that $\pi$ contains the simsun pattern $213$ and let $bac$ an occurrence of such pattern. Let $x$ be minimum of the symbols $y$ appearing in $\pi$ weakly to the right of $c$ such that $a < y \leq c$. Then in the tree $\phi(\pi)$ the nodes labelled by $a, b, c$ and $x$ (with $c$ and $x$ possibly coincident) form an occurrence of a $\blacksquare$-subtree. \hfill $\square$

We say that a b.i.t. is $\blacksquare$-avoiding if it does not contain $\blacksquare$-subtrees, and we denote by $T_n(\blacksquare)$ the subset of $\blacksquare$-avoiding trees of $T_n$. Let $t_{n,\ell}$ be the number of elements of $T_n(\blacksquare)$ whose leftmost node in the symmetric order (namely, the initial symbol in the corresponding permutation) is labelled by $\ell$. We have the following result.

Theorem 2. The numbers $t_{n,\ell}$ satisfy the following recurrence

$$ t_{n,\ell} = \begin{cases} \sum_{k=1}^{n-1} \sum_{i,j} \binom{\ell-j-2}{i-1} \binom{n-\ell}{k-i} t_{k,i} t_{n-1-k,j} & \text{if } \ell \geq 2 \\ \sum_{j} t_{n-1,j} & \text{if } \ell = 1 \end{cases} $$

with initial conditions $t_{0,i} = \delta_{0,i}$ and $t_{1,i} = \delta_{1,i}$.

Proof. Every tree in $T_n(\blacksquare)$ can be obtained by

- choosing an integer $k$, $1 \leq k \leq n - 1$,
- choosing a tree $T_L$ in $T_k(\blacksquare)$,
- choosing a tree $T_R$ in $T_{n-1-k}(\blacksquare)$,
- appending to a root $T_L$ as the left subtree and $T_R$ as the right subtree,
- modifying the labels of $T_L$ and $T_R$ so that the resulting tree does not contain $\blacksquare$ substructures, and its leftmost node has a fixed label $\ell$.

If $\ell = 1$, then the left subtree is empty. We only need to choose the right subtree in $T_{n-1}(\blacksquare)$ and increase each label by 1. Suppose now $\ell > 1$. Choose a left and a right subtree $T_L$ and $T_R$, respectively, of the appropriate size. Denote by $i$ ($j$ respectively) the label of the leftmost node of $T_L$ (resp. $T_R$). We may have several ways to modify the labels of $T_L$ before branching it to the root. The chosen set of labels must satisfy the following conditions:

- they must be greater than or equal to $j + 2$
the $i$-th smaller label must be equal to $l$.

Then we must choose $i - 1$ labels in the interval \(\{j + 2, j + 3, \ldots, \ell - 1\}\) \(\binom{\ell - j - 2}{i - 1}\) choices) and $k - i$ labels in the interval \(\{\ell + 1, \ell + 2, \ldots, n\}\) \(\binom{n - \ell}{k - i}\) choices). We attach the chosen labels to the nodes of $T_L$ according to the initial labelling and assign the remaining labels to $T_R$ with the same criterion.

**Example 3.** We illustrate the second part of the proof. If we choose

\[
T_L = \begin{array}{c}
1 \\
\downarrow \downarrow \\
4 & 2 \\
\downarrow \\
5 & 3
\end{array} \in T_5(\mathfrak{D})
\]

and

\[
T_R = \begin{array}{c}
1 \\
\downarrow \\
3 & 2 \\
\downarrow \\
4 & 6 \\
\downarrow \\
5
\end{array} \in T_6(\mathfrak{D})
\]

then $i = 4$, $j = 3$, $k = 5$. Suppose that $n = 12$ and that we want to construct a tree $T \in T_{12}(\mathfrak{D})$ with $\ell = 9$. Then we have to choose $i - 1 = 3$ elements in \(\{j + 2, \ldots, \ell - 1\} = \{5, 6, 7, 8\}\) and $k - i = 1$ element in \(\{\ell + 1, \ldots, n\} = \{10, 11, 12\}\). If, for example, we choose 5, 6, 8 from the first set and 11 from the second one we get

\[
T = \begin{array}{c}
1 \\
\downarrow \\
5 & 2 \\
\downarrow \\
9 & 6 & 4 \\
\downarrow \\
11 & 8 & 7 & 3 \\
\downarrow \\
10 & 12
\end{array}
\]

From the previous Theorem it follows that the first values of the sequence

\[
\{\|T_n(\mathfrak{D})\|\}_{n \geq 0} = \left\{\sum_{\ell \geq 0} t_{n,\ell}\right\}_{n \geq 0}
\]

The electronic journal of combinatorics 27(3) (2020), #P3.45
are 1, 1, 2, 5, 15, 53, 217, 1013, \ldots This sequence is not present in [11].

4 Permutations avoiding the simsun pattern 213 and $\Sigma \subseteq S_3$

Now we consider permutations that avoid the simsun pattern 213 and a set of patterns $\Sigma$ of length three in the classical sense.

A permutation that avoids the simsun pattern 213 can contain the pattern 213, namely, it can contain the subsequence $bac$ with $a < b < c$, only if one of the following two cases occurs.

- Between $b$ and $a$ there is a symbol $x < a$. In this case $xac$ is an occurrence of the pattern 123 and $bxa$ is an occurrence of 312.

- Between $a$ and $c$ there is a symbol $x$ such that $a < x < b$. In this case $axc$ is an occurrence of the pattern 123 and $bax$ is an occurrence of 312.

From the previous observations it follows that a permutation $\pi$ avoids the simsun pattern 213 if and only if each occurrence of 213 in $\pi$ is part of an occurrence of 3124. Note that the condition of avoiding the simsun pattern 213 cannot be rephrased as the avoidance of a barred pattern.

Since 3124 contains the classical patterns 213, 123 and 312, if $\Sigma$ contains at least one of those patterns, then

$$S_n(213^S, \Sigma) = S_n(213, \Sigma)$$

and in such cases we have again avoidance in the classical sense.

Thus, the only nontrivial cases correspond to the sets $\Sigma$ such that $\Sigma \subseteq \{132, 231, 321\}$.

4.1 $S_n(213^S, 132)$

Denote by $RCT_n$ the image of the set $S_n(213^S, 132)$ under the map $\phi$. Notice that if a $\Sigma$-avoiding tree contains the subtree

\[
\alpha = \begin{cases} \begin{array}{c} a \\ b \\ c \end{array} & \begin{array}{c} a < b < c \end{array} \end{cases}
\]

(with $a < b < c$), then the corresponding permutation has an occurrence of the pattern 132. As a consequence, if a tree $t$ is in $RCT_n$ then, if a node in $t$ has a right son, this son
cannot have a left son. Moreover every tree $t$ in $RCT_n$ must avoid the subtree

![Tree Diagram]

where $a < b < c$ and where the dashed paths have arbitrary length.

We will say that a $\sqcup$-avoiding tree that avoids also the subtrees $\alpha$ and $\beta$ is a right-comb. It is easily seen that the set $RCT_n$ is precisely the set of right-combs with $n$ nodes.

The following figure represents the shape of a right-comb.

![Right-Comb Diagram]

Now we will establish a recurrence for the numbers of right-combs. Denote by $a_n$ the cardinality of $RCT_n$.

**Theorem 4.** The sequence $\{a_n\}_{n \geq 0}$ satisfies

$$a_n = 2a_{n-1} + \sum_{i=1}^{n-2} a_i \cdot (a_{n-i-1} - a_{n-i-2}) \quad \forall n \geq 2$$

with $a_0 = a_1 = 1$.

**Proof.** Given a tree $t$ in $RCT_{n-1}$, we can always add a son with label $n$ either to the left of the leftmost vertex or to the right of the last vertex of the first right branch.

Fix now an integer $i$ between 1 and $n - 2$ and consider a tree $t_1$ in $RCT_i$. Consider also a tree $t_2$ in $RCT_{n-i-1}$ whose maximal label is not attached to its leftmost vertex. Notice that we have $a_{n-i-1} - a_{n-i-2}$ such trees. We can associate to the pair $(t_1, t_2)$ a tree $t_1 \oplus t_2$.
in $RCT_n$, by adding to the rightmost vertex of $t_1$ a right son labelled $i + 1$, increasing by $i + 1$ each label in $t_2$ and pasting the root of $t_2$ to the left of the leftmost vertex of $t_1$.

Every tree $t$ in $RCT_n$ whose vertex with label $n$ is neither the leftmost one nor at the end of the first right branch can be obtained in this way. In fact, given such a tree

- let $i + 1$ be the maximal label on the first right branch,
- consider the subtree $t_1$ ($t_2$, respectively) of nodes labelled by $1, 2, \ldots, i$, $(i + 2, \ldots, n$, respectively).

Then $t = t_1 \oplus t_2$.

**Example 5.** Let

![Tree Diagram]

Then

![Tree Diagram]

The sequence $\{a_n\}_{n \geq 0}$ is (up to a shift) sequence A105633 in [11].
4.2 $S_n(213^S, 231)$

Similarly to the previous case, the set $S_n(213^S, 231)$ corresponds under the map $\phi$ to the subset of $T_n(\emptyset)$ of trees avoiding the subtree

\[
\alpha' = \begin{array}{c}
\text{a} \\
\text{b} \\
\text{c}
\end{array}
\]

(with $a < b < c$) and

\[
\beta' = \begin{array}{c}
\text{b} \\
\text{a} \\
\text{c}
\end{array}
\]

where $a < b < c$ and where the dashed paths have arbitrary length. We denote this subset by $LCT_n$ and call the elements of this set left-combs. Let $b_n$ be the cardinality of $LCT_n$. Now we prove that the sequence $\{b_n\}_{n \geq 0}$ satisfies the same recurrence of $\{a_n\}_{n \geq 0}$ and hence

\[|LCT_n| = |RCT_n|.
\]

**Theorem 6.** The sequence $\{b_n\}_{n \geq 0}$ satisfies

\[b_n = 2b_{n-1} + \sum_{j=1}^{n-2} b_j \cdot (b_{n-j-1} - b_{n-j-2}) \quad \forall n \geq 2
\]  \hspace{1cm} (1)

with $b_0 = b_1 = 1$.

**Proof.** To prove recurrence (1) we will partition the set $LCT_n$ into three non-intersecting subsets.

In fact, given a tree $t$ in $LCT_n$ we have three possible cases.

**Case 1:** The root of $t$ has no left son. Such trees are in bijection with the set $LCT_{n-1}$ (by removing the root). Hence we have $b_{n-1}$ trees with $n$ nodes of this kind.

**Case 2:** The root of $t$ has no right son. There is only one left-comb with $n$ nodes consisting of a single left branch.

**Case 3:** The root of $t$ has both a left and a right son. Let $h$ be the label of the left son of the root. Note that $h > 2$. Consider now the subtree $T_1$ consisting of all vertices of $t$ labelled with $2, 3, \ldots, h - 1$. Let $t^*$ be the subtree of $t$ obtained by
removing $\overline{t_1}$ from the right subtree of the root of $t$. Denote by $\overline{t_2}$ the tree whose root is the vertex of $t$ with label $h$, whose right subtree is $t^*$, and whose left subtree is the left branch stemming from $h$. Let $t_1$ and $t_2$ be the trees obtained from $\overline{t_1}$ and $\overline{t_2}$ by renormalization of the labels, respectively. The tree $t$ is uniquely determined by the pair $(t_1, t_2)$. We will write $t = t_1 \otimes t_2$. Note that $t_1$ is a tree in $\text{LCT}_{n-h-2}$, while $t_2$ is a tree which satisfies all the conditions of the trees in $\text{LCT}_{n-h+1}$, except for the fact that the left son of the root can also be labelled by 2.

**Example 7.** Let 

$$t = \begin{array}{c}
1 \\
5 \\
9 \\
4 \\
2 \\
3 \\
6 \\
8 \\
7 \\
\end{array}$$

then $t = t_1 \otimes t_2$ with 

$$t_1 = \begin{array}{c}
1 \\
3 \\
2 \\
\end{array} \quad \text{and} \quad t_2 = \begin{array}{c}
1 \\
5 \\
4 \\
3 \\
\end{array}$$

The edges of $t$ corresponding to $t_2$ are denoted by thick lines. In this example $t_1 \in \text{LCT}_3$, $t_2 \in \text{LCT}_5$ and $t \in \text{LCT}_9$.

**Example 8.** Let 

$$t = \begin{array}{c}
1 \\
5 \\
6 \\
4 \\
2 \\
3 \\
8 \\
7 \\
9 \\
10 \\
\end{array}$$
then \( t = t_1 \otimes t_2 \) with

\[
t_1 = \begin{array}{ccc}
1 & 2 & 3 \\
\end{array} \\
\]

\[
t_2 = \begin{array}{ccc}
2 & 3 & 4 \\
5 & \end{array} \\
\]

and

Note that \( t_1 \in LCT_3, \ t \in LCT_{10}, \) but \( t_2 \notin LCT_6, \) since it contains a \( \Box \)-subtree given by the nodes 1, 2, 4.

There are three possible situations.

Subcase 3.1: \( t_2 \) is an arbitrary tree in \( LCT_{n-h+1} \) and, since \( t = t_1 \otimes t_2 \) must belong to \( LCT_n, t_1 \) is a tree in \( LCT_{h-2} \) such that its rightmost vertex does not have a left son. In order to compute the number of such trees we proceed as follows. If \( s \) is an element of \( LCT_1 \) such that its rightmost vertex has a left son, the labels of these last two vertices are consecutive, since \( s \) must avoid \( \beta'. \) As a consequence, the number of such trees is \( b_{n-1}. \) Hence we have

\[
\sum_{j=1}^{n-3} b_j \cdot (b_{n-j-1} - b_{n-j-2}) + b_{n-2}
\]

trees in \( LCT_n \) obtained as product of smaller trees of these types. We observe that the term \( b_{n-2} \) refers to the case when \( t_2 \) is an arbitrary tree in \( LCT_{n-2} \) and \( t_1 \) is the tree with one node.

Subcase 3.2: \( t_2 \) is a tree in \( LCT_{n-h+1} \) given by a non-empty sequence of left edges or the tree with one node, and \( t_1 \) is a tree in \( LCT_{h-2} \) such that its rightmost vertex has a left son. The number of trees in \( LCT_n \) obtained in this way is

\[
b_{n-3} + b_{n-4} + \cdots + b_1.
\]

Subcase 3.3: \( t_2 \) is a tree which satisfies all the conditions of the trees in \( LCT_{n-h+1} \) except for the fact that the left son of the root is labelled by 2 (and the root has a right son). Once again, since \( t = t_1 \otimes t_2 \in LCT_n, \) then \( t_1 \) belongs to \( LCT_{h-2} \) and its rightmost vertex does not have a left son (notice that \( t_1 \) can also be the tree with a single node).

We denote by \( \hat{LCT}_{n-h+1} \) the set of trees which satisfy all the conditions of the trees in \( LCT_{n-h+1} \) except for the fact that the left son of the root is labelled by 2 (and the root has a right son).
In order to enumerate the elements of the set $LCT_j$, $j \geq 3$, we observe that a tree $w \in LCT_j$ in which the right son of the root is labelled by $k$ must have a left branch stemming from the root whose first labels are $1, 2, \ldots, k-1$. Removing the nodes labelled from 2 to $k-1$ and scaling the remaining labels we get an arbitrary tree in $LCT_{j-k-2}$ different from the tree given by a single left branch (hence there are $b_{j-k-2}$ possible choices for such tree). This implies

$$|LCT_j| = (b_{j-1} - 1) + (b_{j-2} - 1) + \cdots + (b_2 - 1).$$

The number of trees $t_1 \in LCT_i$ whose rightmost vertex does not have a left son is $b_i - b_{i-1}$, hence the total number of trees obtained as a product of the type explained above is

$$\sum_{j=3}^{n-3} ((b_{j-1} - 1) + (b_{j-2} - 1) + \cdots + (b_2 - 1)) \cdot (b_{n-j-1} - b_{n-j-2}) + (b_{n-3} - 1) + (b_{n-4} - 1) + \cdots + (b_2 - 1)$$

where the sum in the second line equals the number of the trees $t_1 \otimes t_2$, with $t_1$ being a single node. It is easy to see that the expression above reduces to

$$(b_2 - 1)b_{n-4} + (b_3 - 1)b_{n-5} + \cdots + (b_{n-3} - 1)b_1.$$

We now proceed by induction on $n$. The base case with $n = 2$ is trivial. Suppose by induction that

$$b_{n-1} = 2b_{n-2} + \sum_{j=1}^{n-3} b_j \cdot (b_{n-j-2} - b_{n-j-3}).$$

This implies that

$$\sum_{j=1}^{n-3} b_j b_{n-j-2} = b_{n-1} - 2b_{n-2} + \sum_{j=1}^{n-4} b_j b_{n-j-3} + b_{n-3}b_0$$

and, iterating, we obtain

$$\sum_{j=1}^{n-3} b_j b_{n-j-2} = b_{n-1} - b_{n-2} - 1. \quad (2)$$

Now we add all the contributes from Cases 1,2 and 3. We get

$$b_n = b_{n-1} + \sum_{j=1}^{n-3} b_j \cdot (b_{n-j-1} - b_{n-j-2}) + b_{n-2} + b_{n-3} + \cdots + b_1 + 1$$

$$+ (b_2 - 1)b_{n-4} + (b_3 - 1)b_{n-5} + \cdots + (b_{n-3} - 1)b_1 =$$

$$b_{n-1} + \sum_{j=1}^{n-3} b_j \cdot (b_{n-j-1} - b_{n-j-2}) + b_{n-2} + 1$$

$$+ b_{n-3} + b_2b_{n-4} + b_3b_{n-5} + \cdots + b_{n-3}b_1.$$
Exploiting identity (2), the last row of the previous equation can be rewritten as $b_{n-1} - b_{n-2} - 1$, hence we get

$$b_n = b_{n-1} + \sum_{j=1}^{n-3} b_j \cdot (b_{n-j-1} - b_{n-j-2}) + b_{n-2} + 1$$

$$+ b_{n-1} - b_{n-2} - 1 =$$

$$2b_{n-1} + \sum_{j=1}^{n-2} b_j \cdot (b_{n-j-1} - b_{n-j-2}).$$

as desired.

4.3 $S_n(213^S, 321)$

In order to enumerate the set $S_n(213^S, 321)$ it is more convenient to focus on permutations themselves rather than studying the properties of the associated trees. Starting from a permutation $\pi \in S_{n-1}(213^S, 321)$, with $n \geq 3$, we can obtain a permutation $\hat{\pi} \in S_n(213^S, 321)$ by inserting the symbol $n$ in one of the following positions. Write $\pi = \sigma x_1 x_2 \ldots x_k$, $k \geq 1$, where $x_1 x_2 \ldots x_k$ is the last ascending run of $\pi$. Then we can either insert $n$

- immediately before $x_1$, or
- immediately after $x_i$, for all $i \geq 2$, if any, or
- between $x_1$ and $x_2$ whenever $\sigma$ is the empty permutation (otherwise we would create an occurrence of the consecutive pattern 213).

Denote by $A_{n,h}$ the number of elements of $S_n(213^S, 321)$ such that the last ascending run has length $h$. The above considerations imply that

$$A_{n,k} = A_{n-1,k} + \delta_{k \geq 3} A_{n-1,k-1} + \delta_{n-1 = k+1} A_{n-1,k+1} + \sum_{i=2}^{n-k-1} A_{n-1,k+i}$$

for all $n \geq 3$ and $k \geq 1$, where

$$\delta_P = \begin{cases} 1 & \text{if the proposition } P \text{ is true} \\ 0 & \text{otherwise.} \end{cases}$$

Note that the sequence $\{|S_n(213^S, 321)|\}_{n \geq 0}$, is not present in [11]. The first values of such sequence are 1, 1, 2, 4, 8, 18, 45, 119, ...
4.4 $S_n(213^S, 132, 231)$

The results of Subsections 4.1 and 4.2 imply that the map $\phi$ restricted to $S_n(213^S, 132, 231)$ is a bijection between such set and the set $LCT_n \cap RCT_n$. The trees of this last set consist of a root, a (possibly empty) left branch stemming from the root and a (possibly empty) right branch stemming from the root, as shown in the following figure:

Note that if such a tree has a right branch, the right son of the root has label 2 (otherwise the tree would contain a $\underline{2}$ subtree). As a consequence, we can choose the labels of the nodes on the left branch in the set $\{3, \ldots, n\}$, without constraints.

The only other possible case is the case of a tree with only a left branch. Hence

$$|S_n(213^S, 132, 231)| = \begin{cases} 2^{n-2} + 1 & \text{if } n \geq 2 \\ 1 & \text{if } n = 0, 1. \end{cases}$$

4.5 $S_n(213^S, 132, 321)$

As proved in Subsection 4.1, the set $S_n(213^S, 132)$ corresponds, under the map $\phi$, to the set $RCT_n$. If $\pi \in S_n(213^S, 132, 321)$, the left branch of the right-comb $\phi(\pi)$ has length at most one (otherwise the elements of $\pi$ corresponding to the nodes of such left branch would give rise to a decreasing subsequence). Conversely, it is immediately seen that a right-comb with a left branch of length at most one, i.e. of the form

$$\begin{array}{c}
\bullet \\
/ \\
\bullet
\end{array}$$

corresponds, under the map $\phi^{-1}$, to a permutation in $S_n(213^S, 132, 321)$.

Now, denote by $k$ the length of the leftmost right branch of such a tree. For every $n \geq 2$, there is exactly one tree with $k = 0$ and exactly one tree with $k = n - 1$. If $1 \leq k \leq n - 2$, note that the labels of the nodes of the leftmost right branch are consecutive, otherwise the tree would contain the subtree $\beta$. Hence these labels can be chosen in $n - k - 1$ ways. As a consequence,
\[
|S_n(213^S, 132, 321)| = \begin{cases} 
\frac{n^2-3n+6}{2} & \text{if } n \geq 2 \\
1 & \text{if } n = 0, 1.
\end{cases}
\]

This is (up to a shift) sequence A152948 in [11].

4.6 \( S_n(213^S, 231, 321) \)

The set \( S_n(213^S, 231) \) corresponds, under the map \( \phi \), to the set of left-combs \( LCT_n \), as seen in Subsection 4.2. For every \( \pi \in S_n(213^S, 231, 321) \) the right branches of the tree \( \phi(\pi) \) have length at most one, since the labels of any right branch correspond to a descending sequence in the permutation. Moreover, \( \phi(\pi) \) must avoid also the subtrees of the form

because every labelling of such subtree yields a permutation containing either the pattern 321 or the simsun pattern 213. Hence two nodes of \( \phi(\pi) \) with a left son cannot be consecutive. The following figure represents such a tree

Let \( t \) be a tree in \( \phi(S_n(213^S, 231, 321)) \) with \( n \geq 3 \). If the root of \( t \) does not have a left son, removing the root from \( t \) we get an arbitrary tree in \( \phi(S_{n-1}(213^S, 231, 321)) \). Otherwise, let \( k > 2 \) be the label of the left son of the root. Since the tree \( t \) avoids the subtree \( \beta' \), the nodes with labels \( \{2, \ldots, k-1\} \) have no left son. If we remove from \( t \) such nodes and the root we get an arbitrary tree in \( \phi(S_{n-k}(213^S, 231, 321)) \). Hence the sequence \( \{c_n\} \) with \( c_n = |S_n(213^S, 231, 321)| \) satisfies

\[
c_n = c_{n-1} + c_{n-3} + c_{n-4} + \cdots + c_0.
\]

This is (up to the first term) sequence A005314 in [11].
4.7 $S_n(213^S, 132, 231, 321)$

The previous considerations imply that $\phi(S_n(213^S, 132, 231, 321))$ is the set of trees consisting of a root, a right branch and, possibly, a left edge stemming from the root, as in the figure below

There is only one tree consisting of a single right branch. On the other hand, if the root has a left son and $n \geq 3$, we can choose the label of the left son of the root from the set $\{3, \ldots, n\}$. Hence

$$|S_n(213^S, 132, 231, 321)| = \begin{cases} 
    n - 1 & \text{if } n \geq 3 \\
    n & \text{if } n = 1, 2 \\
    1 & \text{if } n = 0.
\end{cases}$$

5 Connection with barred generalized patterns

A generalized pattern (or vincular pattern) is a classical pattern $\tau$ some of whose consecutive letters may be underlined. A permutation $\pi$ contains the generalized pattern $\tau$ if it contains $\tau$ in the classical sense and the elements corresponding to $\tau_i$ and $\tau_{i+1}$ are consecutive in $\pi$ if $\tau_i \tau_{i+1}$ is underlined in $\tau$.

A barred generalized pattern $\tau$ is a generalized pattern $\tau$ some of whose consecutive letters may be overlined. If $\tau$ is a barred generalized pattern, denote by $\tilde{\tau}$ the generalized pattern obtained from $\tau$ removing the overbars and by $\hat{\tau}$ the generalized pattern obtained from $\tau$ removing the overbarred symbols.

A permutation $\pi$ avoids the barred generalized pattern $\tau$ if every occurrence of $\tilde{\tau}$ in $\pi$ is part of an occurrence of $\hat{\tau}$.

As an example, consider the barred generalized pattern $3\overline{124}$. In the permutations $\pi = 4513762$ the subsequence 437 forms an occurrence of the generalized pattern 213 which is part of an occurrence of 3124 and the same holds for the other occurrences of 213, hence $\pi$ avoids the barred generalized pattern 3\overline{124}.

It is possible to recast the avoidance of the simsun patterns $132^S$ and $213^S$ in terms of barred generalized patterns. In fact, as noted above, $S_n(132^S) = S_n(24\overline{13})$ and by [1, Theorem 2.3] we have also $S_n(132^S) = S_n(24\overline{13}) = S_n(23\overline{1}) = S_n(132)$.

Likewise, it is possible to prove that $S_n(213^S) = S_n(3\overline{124})$.
