Abstract

We propose a likely contribution to severe COVID-19 morbidity by extracellular DNA in neutrophil extracellular traps (NETs). Dornase alfa degrades extracellular DNA to reduce mucus rigidity and accumulation, and was associated with respiratory improvement in a first patient. Dornase alfa should be considered for clinical trials in treatment of severe COVID-19.

Keywords: acute respiratory distress syndrome, COVID-19, DNase I, dornase alfa, Neutrophil extracellular trap

Dornase alfa (Pulmozyme; Genentech, South San Francisco, CA, USA) is recombinant human deoxyribonuclease I, the only drug in its class that acts as a mucolytic by cleaving extracellular chromosomal DNA from neutrophil extracellular traps (NET) and other cell-free DNA. The drug’s on-label clinical use is to reduce the viscosity and quantity of airway mucus in individuals with cystic fibrosis, thereby improving mucociliary clearance [¹]. Dornase alfa is commonly used in individuals with cystic fibrosis, including those with severe complications requiring mechanical ventilation in intensive care units, and is compatible with co-administration of other routine drugs including antibiotics. Off-label use of dornase alfa includes reports treating acute respiratory distress syndrome (ARDS), where the drug can lead to mucus plug clearance and accelerated recovery in humans and mice [²,³]. A controlled clinical trial for treating ARDS with dornase alfa is currently underway [⁴]. In the Critical Care setting, rare and minor adverse effects associated with dornase alfa include voice alteration and rash [¹].

The cellular and molecular mechanisms proposed for dornase alfa activity in severely distressed lungs of individuals with cystic fibrosis and many ARDS patients are as follows. Inflammation results in neutrophilia and neutrophil infiltration in the lungs, where these cells produce NETs, largely comprised of sticky, large chromosomal DNA that physically reinforces airway mucus viscosity and accumulation [⁵,⁶]. Thick mucus that clears poorly can lead to airway obstruction, bronchiectasis, lung injury, hypoxia and respiratory failure. Dornase alfa facilitates airway clearance by breaking up reinforcement of mucus by NETs, by far the greatest source of extracellular DNA in inflamed lungs [⁵,⁶].

Severe cases of coronavirus disease 2019 (COVID-19) have shown an inflammatory neutrophil and mucus-mediated airway exclusion pathway with striking similarities to that described above (Fig. 1). Unlike mild COVID-19, which is often associated with fever and upper-airway symptoms, individuals with severe COVID-19 often progress to an ARDS condition: hypoxaemic respiratory failure associated with neutrophil and neutrophil infiltration in the lungs, thick mucus in bronchi, and bronchiectasis [⁷–¹⁰]. Because lung neutrophilia in ARDS is generally known to involve high NET production [⁵], we feel it is rational to hypothesize that NETs contribute to severe pathology in COVID-19. Indeed, lung neutrophilia and NET production have been shown to contribute to the development of ARDS in other severe viral respiratory infections, including H1N1 influenza [¹¹].

We postulate that nebulized dornase alfa may effectively treat a deleterious effect of NETs in the airways and so promote recovery in individuals with COVID-19-related ARDS (Fig. 1). Dornase alfa can be easily administered to mechanically ventilated patients and is well tolerated in intensive care unit settings. Anecdotally, an individual with...
FIG. 1. Model of how dornase alfa-sensitive neutrophil extracellular traps (NETs) from neutrophils may reinforce mucus accumulation, rigidity and airway occlusion in severe coronavirus disease 2019 (COVID-19). (a) Viral infection causes inflammation and respiratory distress (darkened lungs). Lung-infiltrating neutrophils produce NETs whose large quantities of chromosomal, extracellular DNA are susceptible to degradation by dornase alfa (recombinant human deoxyribonuclease I, right). (b) Close up view of alveoli. Without dornase alfa treatment (left), NETs reinforce the accumulation and rigidity of mucus that can increase lung injury and reduce oxygenation. Dornase alfa treatment (right) reduces NET-mediated reinforcement of mucus, making it less rigid (lighter yellow) and facilitating mucus clearance, so reducing lung injury and increasing gas exchange. (c) The rate at which recovery from severe COVID-19 occurs naturally (left, thin arrow) might be increased by dornase alfa treatment (right, thicker arrow). Figure was created with BioRender.
COVID-19 who had been intubated for 5 days was given 3 days of nebulized dornase alfa (2.5 mg twice daily) with continued standard intensive care unit care. Improvements in oxygenation and lung compliance were observed comparing before with after the 3-day period (changes: arterial oxygen partial pressure (PaO2)/fractional inspired oxygen (FiO2) = P/F, 212 to 305; FiO2, 65% to 40%; positive end-expiratory pressure (PEEP), 20 to 14). Four additional days were followed by extubation and six more days in hospital before the patient was considered recovered and discharged home. At this juncture of a rapidly evolving pandemic associated with high mortality in severely ill individuals and the concepts discussed above, we suggest the consideration of including inhaled dornase alfa in clinical trials for severe COVID-19 associated with ARDS.
