Abstract. In this paper, we propose a new high order semi-implicit scheme for the all Mach full Euler equations of gas dynamics. Material waves are treated explicitly, while acoustic waves are treated implicitly, thus avoiding severe CFL restrictions for low Mach flows. High order accuracy in time is obtained by semi-implicit temporal integrator based on the IMEX Runge-Kutta (IMEX-RK) framework. High order in space is achieved by finite difference WENO schemes with characteristic-wise reconstructions adapted to the semi-implicit IMEX-RK time discretization. Type A IMEX schemes are constructed to handle not well-prepared initial conditions. Besides, these schemes are proven to be asymptotic preserving and asymptotically accurate as the Mach number vanishes for well-prepared initial conditions. Divergence-free property of the time-discrete schemes is proved. The proposed scheme can also well capture discontinuous solutions in the compressible regime, especially for two dimensional Riemann problems. Numerical tests in one and two space dimensions will illustrate the effectiveness of the proposed schemes.

Keywords. All Mach number, full Euler Equations, Asymptotic Preserving, Asymptotically Accurate, finite difference WENO, characteristic-wise reconstruction.

1 Introduction

Computational fluid dynamics (CFD) has been a very active research field in the past decades. Numerical methods developed in this area generally can be divided into two categories, which are classified by the dimensionless Mach number. For moderate to high Mach number compressible effects have to be taken into account, while for low Mach number the flow can be considered incompressible or weakly compressible. For compressible flows, most numerical solutions are obtained by Godunov type shock capturing schemes for compressible Euler equations, which have the structure of a hyperbolic system of conservation laws \[ \frac{\partial U}{\partial t} + \nabla \cdot F(U) = 0 \] with \( U \) being the conserved variables and \( F(U) \) the flux vector. For incompressible flows, preserving incompressibility and resolving vortex dynamics are among the main purposes [13, 46, 24].

There are, however, circumstances in which flows with a wide range of Mach number appear, making it desirable to develop numerical methods which can be applied for fluid flows at any speed, as already shown in the pioneering work of Harlow and Amdsen [28, 29]. However, due to the different physical mechanisms and mathematical characteristics for the governing equations at different speeds, the development of efficient and effective numerical methods to capture flows with different compressibility is challenging [34, 20, 11], and a lot of progress has

been made only recently. For hyperbolic systems, waves propagate at finite speeds. Numerical methods have to resolve all the space and time scales that characterize these waves. Most shock capturing schemes devoted to such systems are obtained by explicit time discretization, and the time step has to satisfy a stability restriction, known as the CFL condition: it is limited by the size of the spatial mesh divided by the fastest wave speed. For compressible flows with Mach number greater than, say, 0.1, such a restriction is not a problem: indeed, if one is interested in resolving all the waves, accuracy and stability restrictions on space and time discretization are of similar nature. However, for low Mach flows, acoustic waves usually carry a negligible amount of energy. If one is not interested in resolving them, then the system becomes stiff: stability limitations on the time step are much stricter than the restrictions imposed by accuracy \[48, 49\]. In such cases, one may resort to implicit time discretization to avoid the acoustic CFL restriction. However, shock capturing schemes are highly non-linear, and a naive implicit version of them risks to be very inefficient. Furthermore, numerical viscosities for Godunov-type schemes are inversely proportional to the Mach number, introducing excessive numerical dissipations on the slow waves \[19\]. Preconditioning techniques are adopted to cure the large numerical diffusion as discussed in \[48, 50, 37\], but such techniques are effectively applicable only if Mach numbers are not too small.

On the other hand, as the Mach number vanishes, the flow converges to the incompressible limit. For the full Euler equations, at the incompressible limit, the density remains constant along the fluid particle trajectories, and the pressure waves propagate with infinite speed. Energy conservation equation reduces to the incompressibility condition \[\nabla \cdot \mathbf{u} = 0\] on the velocity field \[14\], so that the pressure and the density are decoupled. The pressure turns out to act as a Lagrange multiplier to enforce incompressibility of the flow \[34\]. A rigorous proof for the compressible flow converging to the incompressible one as the Mach number goes to zero is given in \[32\]. An effective approach to deal with low Mach flows is given by pressure-based algorithms, such as, for example, the one by Casulli and Greenspan \[12\], in which a semi-implicit treatment of the pressure is incorporated in a scheme for compressible flow. The authors use an upwind discretization on the material wave, and an implicit equation for the pressure, which is solved by a SOR-type method. Several authors have subsequently worked on the development of semi-implicit methods \[34, 38\] based on low-Mach asymptotics \[32\]. However, many of such schemes are specifically designed to deal with low Mach flows. When the fluid flow is compressible at large speed, shock discontinuities may form and propagate. In these cases, it is necessary to resort to conservative schemes (density-based schemes) which correctly capture possible shocks.

Recently several papers have been written along these lines, see for example \[18, 25, 41, 22, 9, 8\] for isentropic Euler and Navier-Stokes equations, or \[16, 15, 21, 51, 20, 10\] for full Euler and Navier-Stokes equations. However, most finite volume and finite difference schemes for full Euler equations are second order accurate in space and time, while existing high order schemes developed for all Mach flows in isentropic Euler equations are not robust enough to be directly extended to the full Euler equations.

The aim of the present paper is to design a new high order finite difference shock capturing scheme for the full compressible Euler equations. Finite difference weighted essentially non-oscillatory (WENO) schemes are used for spatial discretization, while high order semi-implicit IMEX Runge-Kutta (SI-IMEX-RK) methods are adopted for time discretization. New IMEX schemes are suitably designed for stability and accuracy, with time stepping size independent of the Mach number \(\varepsilon\). A key feature of the scheme is the implicit treatment of acoustic waves, while material waves are treated explicitly by WENO reconstructions of numerical fluxes. In particular, a suitable local Lax-Friedrich flux with characteristic-wise WENO reconstruction has been adopted for the explicit convective terms, while component-wise WENO reconstructions with zero numerical diffusion is used for implicit acoustic terms. The method is able to capture shocks and discontinuities in an essentially non-oscillatory fashion in the compressible regime. In order to avoid the nonlinearity from the equation of state (EOS), a semi-implicit treatment similar to the one adopted in \[9\] is used, leading to a linearized elliptic equation for the pressure, as described in Section 3.2. Another essential ingredient of the scheme design is to split the pressure into a thermodynamic pressure and a hydrodynamic one, using a similar idea adopted in \[16\] but with a fixed splitting parameter \(\alpha\). The thermodynamic pressure is used for the characteristic reconstructions, while the hydrodynamic pressure is obtained by solving an elliptic
system. We show that the resulting scheme is asymptotic preserving (AP) and asymptotically accurate \cite{39 31}, i.e., it is a consistent and high order discretization of the compressible Euler equations and, in the limit as $\varepsilon \to 0$, with $\Delta x$ and $\Delta t$ fixed, it becomes a consistent and high order discretization of the incompressible Euler equations.

The rest of the paper is organised as follows. We recall the low Mach limit for the full compressible Euler equations in Section 2. We start Section 3 by introducing a first order semi-implicit scheme in time, then we describe the extension to high order time discretization using IMEX methods in Section 3.2, in particular we design IMEX methods called of type A \cite{4}, which will be robust enough to solve the elliptic equation for the pressure. We close the section with a description of high order spatial discretization obtained by characteristic-wise and component-wise WENO strategies. The asymptotic preserving (AP) and asymptotic accuracy (AA) properties of the scheme are given in Section 4. Numerical tests are performed in Section 5, with the conclusion drew in the last section.

2 Low Mach limit for the full Euler equations

We consider the compressible Euler equations for an ideal gas in the non-dimensional form \cite{39 19 16}:

$$
\begin{align*}
\rho_t + \nabla \cdot (\rho \mathbf{u}) &= 0, \\
(\rho \mathbf{u})_t + \nabla \cdot (\rho \mathbf{u} \otimes \mathbf{u}) + \frac{1}{\varepsilon^2} \nabla p &= 0, \\
E_t + \nabla \cdot [(E + p)\mathbf{u}] &= 0,
\end{align*}
$$

(2.1)

with the EOS for a polytropic gas satisfying

$$
E = \frac{p}{\gamma - 1} + \frac{\varepsilon^2}{2} \rho |\mathbf{u}|^2,
$$

(2.2)

where $\gamma > 1$ being the ratio of specific heats. The parameter $\varepsilon$ represents a global Mach number characterizing the non-dimensionalization. System (2.1) is hyperbolic and the eigenvalues along the direction $\mathbf{n}$ are: $\lambda_1 = \mathbf{u} \cdot \mathbf{n} - c_s/\varepsilon$, $\lambda_2 = \mathbf{u} \cdot \mathbf{n}$, $\lambda_3 = \mathbf{u} \cdot \mathbf{n} + c_s/\varepsilon$ with $c_s = \sqrt{\gamma p/\rho}$.

When the reference Mach number is of order one, namely $\varepsilon = \mathcal{O}(1)$, modern shock capturing methods are able to compute the formation and evolution of shocks and other complex structures with high resolutions at a reasonable cost. On the other hand, when the flows are slow compared to the speed of sound, i.e. $\varepsilon \ll 1$, we are near the incompressible regime. In such a situation, pressure waves become very fast compared to material waves. Standard explicit shock-capturing methods require a CFL time restriction dictated by the sound speed $c_s/\varepsilon$ to integrate the system. This leads to the stiffness in time, see e.g. \cite{25 18 16}, where the time discretization is constrained by a stability condition given by $\Delta t < \Delta x/\lambda_{\text{max}} = \mathcal{O}(\varepsilon \Delta x)$, here $\Delta t$ is the time step size, $\Delta x$ is the mesh size and $\lambda_{\text{max}} = \max_{\Omega} (|\mathbf{u}| + c_s/\varepsilon)$ on the computational domain $\Omega$. This restriction results in an increasingly large computational time for low Mach fluid flows. Moreover, excessive numerical viscosity (scales as $\varepsilon^{-1}$) in standard upwind schemes, leads to highly inaccurate solutions \cite{48 49}. Thus, it is of challenge and great importance to design numerical schemes, not only for shock-capturing, but also with consideration on stability and consistency in the incompressible limit, i.e. with asymptotic preserving (AP) property. In fact, in the low Mach limit, one is not interested in resolving the pressure waves; instead the fluid pressure serves as a Lagrangian multiplier in preserving the incompressibility of the velocity field. For the theoretical analysis of convergence from compressible flow to incompressible equations, such as $\varepsilon \to 0$, we refer to Klainerman and Majda \cite{32 33} for a rigorous study in this low Mach limit.

Here we recall the classical formal derivation of the incompressible Euler equations from the rescaled compressible Euler equations for an ideal gas \cite{21} with the EOS \cite{22}. We consider an asymptotic expansion ansatz for the following two main variables:

$$
p(x, t) = p_0(x, t) + \varepsilon^2 p_2(x, t) + \cdots ,
$$

$$
u(x, t) = u_0(x, t) + \varepsilon u_1(x, t) + \cdots ,
$$

(2.3)
and insert them into the full Euler equations (2.1). First, for the leading order \( O(\varepsilon^{-2}) \), we formally find: \( \nabla p_0(x, t) = 0 \), i.e. pressure \( p_0 \) is constant in space, up to fluctuations of \( O(\varepsilon^2) \) and by (2.2), assuming for \( E \) an expansion as \( p \) in (2.3), we get \( E_0 = p_0/(\gamma - 1) \). Then we formally find to \( O(1) \),

\[
\begin{align*}
\partial_t \rho_0 + \nabla \cdot (\rho_0 u_0) &= 0, \\
\partial_t (\rho_0 u_0) + \nabla \cdot (\rho_0 u_0 \otimes u_0) + \nabla p_2 &= 0, \\
\partial_t E_0 + \nabla \cdot [(E_0 + p_0) u_0] &= 0.
\end{align*}
\]

(2.4)

From the energy equation in (2.4), with the EOS (2.2) and denoting \( d/dt = \partial/\partial t + u_0 \cdot \nabla \), we have

\[ \nabla \cdot u_0 = -\frac{1}{\rho_0^\gamma} \frac{dp_0}{dt}. \]

(2.5)

Now integrating the equation (2.5) over a spatial domain \( \Omega \) with no-slip or periodic boundary conditions, we get \( \int_\Omega \nabla \cdot u_0 \, d\mathbf{x} = \int_{\partial\Omega} u_0 \cdot \mathbf{n} \, ds = 0 \), where \( \mathbf{n} \) is the unit outward normal vector along \( \partial\Omega \), and this implies \( p_0 \) is constant both in space and time, i.e. \( p_0 = \text{Const} \). Then, back into (2.5), one finds the divergence constraint \( \nabla \cdot u_0 = 0 \) in the zero Mach number limit. In summary, we have:

\[
\begin{align*}
p_0 &= \text{Const.}, \quad \nabla \cdot u_0 = 0, \\
\partial_t \rho_0 + \nabla \cdot (\rho_0 u_0) &= 0, \\
\partial_t (\rho_0 u_0) + \nabla \cdot (\rho_0 u_0 \otimes u_0) + \nabla p_2 &= 0.
\end{align*}
\]

(2.6)

As a direct consequence of \( \nabla \cdot u_0 = 0 \), we obtain from the mass-continuity equation \( dp_0/dt = 0 \), namely the material derivative of the density is zero. This means that the density is constant along the particle trajectories. In particular, if the initial density is constant in space, the density of the fluid is constant in space and time. Note that

\[ p_2 = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon^2} (p - p_0) \]

(2.7)

is implicitly defined by the constraint \( \nabla \cdot u_0 = 0 \), which satisfies the following elliptic equation:

\[ -\nabla \cdot \left( \frac{1}{\rho_0} \nabla p_2 \right) = \nabla \cdot ((u_0 \cdot \nabla) u_0). \]

(2.8)

Finally, we assume the initial condition is well-prepared \([32, 33, 19, 34]\), that is, the initial condition for (2.3) is compatible with the equations at various orders of \( \varepsilon \):

\[
\begin{align*}
p(t = 0, \mathbf{x}) &= p_0 + \varepsilon^2 p_2(0, \mathbf{x}) + \cdots \\
u(t = 0, \mathbf{x}) &= u_0(\mathbf{x}) + O(\varepsilon),
\end{align*}
\]

(2.9)

with \( p_0 = \text{Const.} \) and \( \nabla \cdot u_0 = 0 \) and we impose \( \rho(0, \mathbf{x}) = \rho_0(\mathbf{x}) \), with \( \rho_0(\mathbf{x}) \) being a strictly positive function. Note that well-prepared initial conditions are required if we want that the solution to the \( \varepsilon \)-dependent problem smoothly converges to the solution of the limiting incompressible problem. Furthermore, well-prepared initial condition is an important requirement to design AP schemes. It is crucial to preserve the constant state for leading order terms of \( p \) and \( E \), as well as that the divergence free constraint on the leading order term of \( u \). For an arbitrary initial condition, an initial layer will appear, which requires a numerical resolution at the \( \varepsilon \)-scale.

### 3 Numerical scheme

In this section, we aim to construct and analyze a class of high order finite difference schemes with the AP property for unsteady compressible flows, when the Mach number \( \varepsilon \) spans several orders of magnitude. The features of our scheme are the following: we design a semi-implicit
IMEX (SI-IMEX) time discretization strategy, so that the scheme is stable with a time stepping constraint independent of the Mach number $\varepsilon$, the AP property is preserved in the zero Mach number limit and the scheme can be implemented in a semi-implicit manner \[1, 3, 2, 5\] to enable effective and efficient numerical implementations. Our scheme preserves the incompressible velocity field in the zero Mach number limit by involving an elliptic solver for the hydrostatic pressure. In this section, the strategy of numerical discretizations is different from the traditional method-of-lines approach, since we first perform time discretization to ensure AP property, after which we apply a suitable space discretization. In particular we adopt high order WENO strategies with characteristic reconstructions tailored to IMEX-type methods in time. The final scheme can successfully capture shocks in the compressible regime, and efficiently solves the equations in the low Mach regime, with CFL condition depending only on fluid velocity.

### 3.1 Semi-implicit treatment

We introduce our proposed strategy of implicit and explicit time discretizations, which is similar in spirit to the first order scheme in \[16\] with a slight modification. We emphasize the special treatment to avoid solving nonlinear equations required by a fully implicit scheme. We rewrite (2.1) as

$$\frac{dU}{dt} = -\nabla \cdot F_E - \nabla \cdot F_{SI}$$  \hspace{1cm} (3.10)

where $U = (\rho, \rho u, E)^T$ and

$$F_E = \begin{pmatrix} q_E \\ \frac{q_E \otimes q_E}{\rho E} + \alpha p_E I \\ 0 \end{pmatrix}, \quad F_{SI} = \begin{pmatrix} 0 \\ \frac{1 - \alpha \varepsilon^2}{\varepsilon^2 - \rho I} p_I \| \\ E_E + \frac{p_E}{\rho I} q_I \end{pmatrix}. \hspace{1cm} (3.11)$$

Subscripts $E$ and $SI$ of $F$ indicate the explicit and semi-implicit treatment of the first and the second term respectively. Several remarks are in order:

1. The parameter $\alpha$ determines the splitting between the explicit and implicit contribution of the pressure: the former ensures that the explicit part is still hyperbolic, with a much smaller sound speed than the physical one, when $\varepsilon \ll 1$, while the latter will ensure much milder stability restrictions. As $\varepsilon$ increases, the explicit contribution becomes more and more relevant. This form of splitting is similar to the one in \[16\], but differs in two main aspects: one is the implicit treatment of $\rho$ in the energy equation in (3.11), which gives a better asymptotic preserving property as will be elaborated in Section 4; the other is the choice of the parameter $\alpha$ in splitting the pressure. In \[16\], $\alpha$ is chosen depending on the Mach number $\varepsilon$. In our proposed scheme, however, $\alpha$ is chosen to be equal to 1 for all $\varepsilon < 1$, and $\alpha = 1/\varepsilon^2$ for $\varepsilon \geq 1$.

2. We use the following EOS for (2.2) to avoid the nonlinearity in the semi-implicit scheme:

$$E_E = \frac{1}{\gamma - 1} p_E + \varepsilon \frac{|q_E|^2}{2 \rho E}, \quad E_I = \frac{1}{\gamma - 1} p_I + \varepsilon \frac{|q_E|^2}{2 \rho E}. \hspace{1cm} (3.12)$$

The subscripts $E$ and $I$ of $q$, $\rho$, $E$ and $p$ indicate the explicit and implicit treatments of the corresponding variables, respectively.

3. For the implicit term $p_I$ in (3.11), it is convenient to introduce a pressure perturbation $p_{I,2}$ \[11\], corresponding to the hydrodynamic pressure in the incompressible limit, defined as

$$p_{I,2} = \frac{p_I - \bar{p}_E}{\varepsilon^2}, \hspace{1cm} (3.13)$$

where $\bar{p}_E$ denotes the spatial average of the pressure $p_E$ computed from the EOS (3.12). In this way the term $p_{I,2}$ will remain finite even as $\varepsilon \to 0$. Then we have

$$\frac{1}{\varepsilon^2} \nabla p_I = \nabla p_{I,2}. \hspace{1cm} (3.14)$$
As an example, we present the scheme as well as the flow chart to update the numerical solution $U^{n+1} = (\rho^{n+1}, q^{n+1}, E^{n+1})^T$ for the first order semi-implicit scheme solving system (2.1). We focus on the time discretization while keeping the space continuous, whose discretizations will be discussed in detail in Section 3.3.

\begin{align}
\frac{\rho^{n+1} - \rho^n}{\Delta t} + \nabla \cdot q^n &= 0, \\
\frac{q^{n+1} - q^n}{\Delta t} + \nabla \cdot \left( \frac{q^n \otimes q^n}{\rho^n} + p^n \mathbb{I} \right) + \frac{1 - \varepsilon^2}{\varepsilon^2} \nabla \rho^{n+1} &= 0, \\
\frac{E^{n+1} - E^n}{\Delta t} + \nabla \cdot \left( E^n + p^n - q^{n+1} \right) &= 0, \
\end{align}

with

\[
\mathcal{F}_E(U^n) \doteq \begin{pmatrix} q^n \\ \left( \frac{q^n \otimes q^n}{\rho^n} \right) + p^n \mathbb{I} \\ 0 \end{pmatrix}, \quad \mathcal{F}_{SI}(U^n, U^{n+1}) \doteq \begin{pmatrix} 0 \\ \frac{1 - \varepsilon^2}{\varepsilon^2} p^{n+1} \mathbb{I} \\ \frac{E^n + p^n}{\rho^{n+1}} - q^{n+1} \end{pmatrix}.
\]

The flow chart based on the semi-implicit scheme is the following:

1. update $\rho^{n+1}$ from (3.15a).
2. we rewrite (3.15b) as

$$q^{n+1} = q^* - \Delta t \frac{1 - \varepsilon^2}{\varepsilon^2} \nabla p^{n+1},$$

with $q^* = q^n - \Delta t \nabla \cdot \left( \frac{q^n \otimes q^n}{\rho^n} + p^n \mathbb{I} \right)$. We substitute $q^{n+1}$ into (3.15c) to get

$$E^{n+1} = E^* + \Delta t \frac{1 - \varepsilon^2}{\varepsilon^2} \nabla \cdot (H^n \nabla p^{n+1}),$$

where $H^n = (E^n + p^n)/\rho^{n+1}$ and $E^* = E^n - \Delta t \nabla \cdot (H^n q^*)$.

3. Now we replace $E^{n+1}$ by $p^{n+1}/(\gamma - 1) + \varepsilon^2 (q^n)^2/(2p^n)$ in (3.18) using (3.12), and with the introduction of (3.13) i.e. $p_{2}^{n+1} \doteq (p^{n+1} - \bar{p}^n)/\varepsilon^2$ where $\bar{p}^t = p^{n+1}$ and $\bar{p}^n = \bar{p}_E$, we rewrite (3.18) as

$$\frac{\varepsilon^2}{\gamma - 1} p_{2}^{n+1} - \Delta t^2 (1 - \varepsilon^2) \nabla \cdot (H^n \nabla p_{2}^{n+1}) = E^{**},$$

where $E^{**} = E^* - \bar{p}^n/(\gamma - 1) - \varepsilon^2 (q^n)^2/(2p^n)$ is explicitly computed. We obtain an elliptic equation (3.19) for $p_{2}^{n+1}$.

4. Finally, we update $q^{n+1}$ from (3.17), and then $E^{n+1}$ from (3.15c).

Note that if $\varepsilon \geq 1$ the implicit pressure contribution in (3.15b) vanishes, so the momentum $q^{n+1}$ is evaluated explicitly. With updated $\rho^{n+1}$ and $q^{n+1}$, $E^{n+1}$ can also be updated in an explicit way from (3.15c).

### 3.2 High order semi-implicit (SI) temporal discretization using IMEX

#### 3.2.1 High order SI-IMEX R-K scheme for all Mach number full Euler system

We generalize the first order scheme (3.15) to high order in the framework of IMEX R-K methods. In order to do so, we follow the idea introduced in [4]. We consider an autonomous system of the form

$$U' = \mathcal{H}(U), \quad U(t_0) = U_0,$$
where $\mathcal{H} : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is a sufficiently regular mapping. We assume an explicit treatment of the first argument of $\mathcal{H}$ (using subscript "E"), and an implicit treatment to the second argument (using subscript "I"), i.e.

$$
\begin{align*}
U_E' &= \mathcal{H}(U_E, U_I), \\
U_I' &= \mathcal{H}(U_E, U_I),
\end{align*}
$$

(3.20)

with initial conditions $U_E(t_0) = U_0$, $U_I(t_0) = U_0$. (3.21)

Then system (3.10) with (3.11) can be rewritten in the form (3.20) where $U = (U_E, U_I)^T$ with $U_E = (\rho_E, q_E, E)^T$, and $U_I = (\rho_I, q_I, E_I)^T$, and $\mathcal{H}(U_E, U_I) = -\nabla \cdot F_E - \nabla \cdot F_{SI}$.

System (3.20) is a particular case of the *partitioned system*, [27]. One can apply an IMEX R-K scheme to (3.20), using the corresponding pair of Butcher *tableau* [11].

$$
\begin{array}{cc}
\hat{c} & A \\
\hat{b}^T &
\end{array}
$$

(3.22)

where $\hat{A} = (\hat{a}_{ij})$ is an $s \times s$ matrix for an explicit scheme, with $\hat{a}_{ij} = 0$ for $j \geq i$ and $A = (a_{ij})$ is an $s \times s$ matrix for an implicit scheme. For the implicit part of the methods, we use a diagonally implicit scheme, i.e. $a_{ij} = 0$, for $j > i$, in order to guarantee simplicity and efficiency in solving the algebraic equations corresponding to the implicit part of the discretization. The vectors $\hat{c} = (\hat{c}_1, ..., \hat{c}_s)^T$, $\hat{b} = (\hat{b}_1, ..., \hat{b}_s)^T$, and $c = (c_1, ..., c_s)^T, b = (b_1, ..., b_s)^T$ complete the characterization of the scheme. The coefficients $\hat{c}$ and $c$ are given by the usual relation

$$
\hat{c}_i = \sum_{j=1}^{i-1} \hat{a}_{ij}, \quad c_i = \sum_{j=1}^{i} a_{ij}.
$$

(3.23)

From now on, it is useful to characterize different IMEX schemes we will consider in the sequel accordingly to the structure of the DIRK method. Following [1] we call: an IMEX-RK method of type A if the matrix $A \in \mathbb{R}^{s \times s}$ is invertible, and we call an IMEX-RK method of type CK if the matrix $A$ can be written as

$$
A = \left( \begin{array}{cc} 0 & 0 \\ 0 & A \end{array} \right),
$$

with $a = (a_{21}, ..., a_{s1})^T \in \mathbb{R}^{(s-1)}$ and the submatrix $\hat{A} \in \mathbb{R}^{(s-1) \times (s-1)}$ is invertible, or equivalently $a_{ii} \neq 0$, $i = 2, ..., s$. In the special case $a = 0$, $b_1 = 0$ the scheme is said to be of type ARS and the DIRK method is reducible to a method using $s-1$ stages. Later, for the consideration of AP property, we consider *stiffly accurate* (SA) implicit schemes, i.e., the implicit part of the Butcher table satisfies the condition $\hat{b}^T = c^T A$, with $c_s = (0, ..., 0, 1)$ and $c_1 = 1$. We will see that SA guarantees that the numerical solution is identical to the last internal stage value of the scheme.

Now an SI-IMEX R-K scheme applied to (3.20) reads

$$
\begin{align*}
U_E^{(i)} &= U_E^{n} + \Delta t \sum_{j=1}^{i-1} \hat{a}_{ij} \mathcal{H}(U_E^{(j)}, U_I^{(j)}), \\
U_I^{(i)} &= U_I^{n} + \Delta t \sum_{j=1}^{i} a_{ij} \mathcal{H}(U_E^{(j)}, U_I^{(j)}),
\end{align*}
$$

(3.24a)

$$
\begin{align*}
U_E^{n+1} &= U_E^{n} + \Delta t \sum_{i=1}^{s} \hat{b}_i \mathcal{H}(U_E^{(i)}, U_I^{(i)}), \\
U_I^{n+1} &= U_I^{n} + \Delta t \sum_{i=1}^{s} b_i \mathcal{H}(U_E^{(i)}, U_I^{(i)}).
\end{align*}
$$

(3.24b)

Apparently, by writing in the form (3.20), we increased the computational cost since we double the number of variables. However, the cost is mainly due to the number of function evaluations, which essentially depends on the semi-implicit scheme, because in (3.24) the identical term $\mathcal{H}(U_E^{(i)}, U_I^{(i)})$ appears in both explicit and implicit parts. Furthermore, if $b_i = b_i$ for all $i$, then $U_E^{n} = U_E^{n+1}$ for all $n > 0$ (provided $U_E^{0} = U_E^{n}$) and therefore the duplication of variables is not necessary. Such a property is of particular relevance for designing time discretization schemes which are asymptotic preserving.
We rewrite the scheme (3.24) in the following new form for the convenience of further discussion

\[ U_E^{(i)} = U^n + \Delta t \sum_{j=1}^{i-1} \tilde{a}_{ij} \mathcal{H}(U_E^{(j)}, U_I^{(j)}), \quad U_I^{(i)} = \tilde{U}_I^{(i)} + \Delta t a_{ii} \mathcal{H}(U_E^{(i)}, U_I^{(i)}), \quad (3.25) \]

where \( \tilde{U}_I^{(i)} = U^n + \Delta t \sum_{j=1}^{i-1} a_{ij} \mathcal{H}(U_E^{(j)}, U_I^{(j)}) \). Denoting \( \tilde{b}_i = b_i \) for all \( i \), finally we have

\[ U^{n+1} = U^n + \Delta t \sum_{i=1}^s b_i \mathcal{H}(U_E^{(i)}, U_I^{(i)}). \quad (3.26) \]

Similar to the first order scheme, we split the pressure into explicit (\( p_E \)) and implicit (\( p_I \)) terms. In order to avoid the nonlinearity in the semi-implicit step we use the following equations of state (3.12), i.e., for the generic stages \( i = 1, \ldots, s \)

\[ E_E^{(i)} = \frac{1}{\gamma - 1} p_E^{(i)} + \varepsilon^2 \frac{|q_E^{(i)}|^2}{2 p_E^{(i)}}, \quad (3.27a) \]

\[ E_I^{(i)} = \frac{1}{\gamma - 1} p_I^{(i)} + \varepsilon^2 \frac{|q_E^{(i)}|^2}{2 p_E^{(i)}}, \quad (3.27b) \]

**Remark 3.1.** The first order scheme (3.15) is the same as applying the following Butcher table to (3.20)

\[
\text{Type A 1:} \quad \begin{array}{ccc}
0 & 0 & 1 \\
0 & 1 & 1 \\
1 & 1 & 1
\end{array}
\]

Formally applying the above tableau (3.28) to the partitioned system (3.20), it reads

\[ U_E^{(1)} = U^n, \]
\[ U_I^{(1)} = U^n + \Delta t \mathcal{H}(U_E^{(1)}, U_I^{(1)}), \]
\[ U^{n+1} = U^n + \Delta t \mathcal{H}(U_E^{(1)}, U_I^{(1)}), \]

which is the first order scheme (3.15), considering \( U_E^{(1)} = U^n \) and \( U_I^{(1)} = U^{n+1} \).

**Remark 3.2.** The authors in [10] proposed a different semi-implicit discretization of the EOS (3.27b) where the kinetic energy in the total energy definition splits into an explicit and an implicit contribution, namely

\[ E_I^{(i)} = \frac{1}{\gamma - 1} p_I^{(i)} + \varepsilon^2 \frac{|q_E^{(i)}|^2}{2 p_E^{(i)}}, \quad (3.29) \]

We performed numerical tests to compare such semi-implicit treatment of the kinetic energy (3.29) with (3.27b). It is found numerically that such semi-implicit treatment (3.29) may produce slightly better error in some test cases. Overall comparable performances are observed.

In order to save space, we decide not to report these results in this paper.

### 3.2.2 Construction of an IMEX R-K scheme

Next, we construct an IMEX R-K Butcher tableau for semi-implicit discretization of all-Mach full Euler system. The construction is based on the following considerations for accuracy and for handling non-well prepared initial data.

1. We require that the implicit part of the IMEX R-K scheme is SA. With such an assumption, one can derive the AP and AA properties of the scheme as discussed in Section 4. Note that if the implicit part of the scheme is A-stable, SA is a sufficient condition to make it L-stable, see [27].
2. The invertibility of the implicit matrix \( A \) of the SI-IMEX R-K scheme is important to handle non-well prepared initial conditions and for proper initialization of the hydrodynamic pressure. In particular, \( a_{11} \neq 0 \) for IMEX R-K schemes of type A. This is critical to solve the pressure wave equation (3.19). If \( a_{11} = 0 \) (e.g. in an IMEX scheme of type ARS), then we cannot have the pressure wave equation, hence no proper value of \( p_{I,2} \) (e.g. see eq. (3.38)) at the first IMEX stage. For further related discussions and analysis, we refer the reader to the following papers [40, 7, 6]. Thus, we construct IMEX R-K of type A for the time discretization.

3. To synchronize \( U_E \) and \( U_I \), the weights for the final stage of the double tableaus should be the same, i.e. \( b_i = \tilde{b}_i \) for \( i = 1 \cdots s \). That is, we keep only one set of numerical solution in the process of updating [4]. Alternatively, we can select a different vector of weights for the \( U_E(t) \), say \( b_i \neq \tilde{b}_i \), which will provide a lower/higher order approximation of the solution for \( U_E(t) \); this can be used to implement a procedure of automatic time step control [26].

4. In order to simplify order conditions, given the equations of state used in the semi-implicit step (3.27), we impose that \( c_i = \tilde{c}_i \) for \( i = 2 \cdots s \). Note that if matrix \( A \) is invertible we have \( c_1 \neq \tilde{c}_1 = 0 \) [40].

Based on the above considerations, we design a high-order IMEX scheme with matrix \( A \) invertible, which is SA and satisfies \( c_i = \tilde{c}_i \) for \( i = 2 \cdots s \). We impose the conditions required for a third order scheme [40] and obtain the following double Butcher tableau

\[
\begin{align*}
\text{Explicit :} & \\
0 & 0 & 0 & 0 & 0 & 0 \\
\gamma & \gamma & 0 & 0 & 0 & 0 \\
0.717933260754 & 0.435866521508 & 0.282066739245 & 0 & 0 & 0 \\
1 & -0.7335434082748750 & 2.150527381100 & -0.416993298352 & 0 & 0 \\
0 & 0 & 1.208496649176 & -0.644363170684 & \gamma & 0 \\
\text{Implicit :} & \\
\gamma & \gamma & 0 & 0 & 0 & 0 \\
\gamma & 0 & \gamma & 0 & 0 & 0 \\
0.717933260754 & 0 & 0.282066739245 & \gamma & 0 & 0 \\
1 & 0 & 1.208496649176 & -0.644363170684 & \gamma & 0 \\
0 & 1.208496649176 & -0.644363170684 & \gamma & 0 & \gamma \\
\end{align*}
\]

with \( \gamma = 0.435866521508 \). We call it SI-IMEX(4,4,3), the triplet \((s, \sigma, p)\) characterizing the number of stages of the implicit scheme \((s = 4)\), the number of stages of the explicit scheme \((\sigma = 4)\) and the order of the scheme \((p = 3)\). A corresponding 2nd order scheme, which we call SI-IMEX(3,3,2) is given as

\[
\begin{align*}
\text{Explicit :} & \\
0 & 0 & 0 & 0 & 0 & 0 \\
\gamma & \gamma & 0 & 0 & 0 & 0 \\
1 & \delta & 1 - \delta & 0 & 0 & 0 \\
0 & 0 & 1 - \gamma & \gamma & 0 & 0 \\
\text{Implicit :} & \\
\gamma & \gamma & 0 & 0 & 0 & 0 \\
\gamma & 0 & \gamma & 0 & 0 & 0 \\
0 & 1 - \gamma & \gamma & 0 & 0 & 0 \\
0 & 0 & 1 - \gamma & \gamma & 0 & 0 \\
\end{align*}
\]

where \( \gamma = 1 - \sqrt{2}/2 \) and \( \delta = -2\sqrt{2}/3 \).

**3.3 High order spatial discretization for all-Mach fluid flows**

Below we describe our spatial discretization strategies that incorporate WENO mechanism to capture shocks in the compressible regime and produce a high order incompressible solver for the flow in the zero Mach limit. One major difficulty, hence the new ingredient in the scheme design, in extending the high order AP scheme for the isentropic Euler system [8] to the full Euler system is about the pressure. In the isentropic case, the pressure is an explicit function
of $\rho$, whereas in the full Euler case the pressure comes from the EOS involving all conserved
variables. As such, we split the pressure into the part involving $p_\text{E}$ obtained from the EOS
\cite{3.27a}, and the part $p_{\text{I,2}}$ obtained by formulating an elliptic equation from a semi-implicit
solver of the system. In this process, the spatial discretization in the scheme formulation
becomes critical for its robustness. There are several ingredients in our spatial discretization
that differentiate our approach from the existing ones in the literature. Firstly, we carefully
apply the WENO procedure for spatial reconstructions of fluxes for the full Euler system which
is a nontrivial generalization from the isentropic one \cite{8}. In particular, we propose to apply the
fifth order characteristic-wise WENO procedure to $F$ (in \eqref{3.11}) of the full Euler system so
that in the compressible regime oscillations could be best controlled; and to apply a component-
wise WENO procedure for the flux functions of $F_{SI}$ (in \eqref{3.11}). We found that such a choice
is optimal in compromising the need from both compressible and incompressible fluid solvers.
The characteristic-wise WENO turns out to be important for compressible Euler system, as
shown in the numerical section. Secondly, following the strategy in our previous work \cite{8}, we
apply a compact high order spatial discretization to second order derivatives terms in \eqref{3.37}.
This is discussed in Section \ref{3.3.2}.

### 3.3.1 WENO spatial discretization

Without loss of generality, we describe our algorithms in a 2D setting. Let
$$U = (\rho, \rho u, \rho v, E)^T,$$
$$\nabla \cdot F_E = \partial_x F_E^x + \partial_y F_E^y, \quad \nabla \cdot F_{SI} = \partial_x F_{SI}^x + \partial_y F_{SI}^y$$
with flux functions in $x$ and $y$ directions
$$F_E^x \; (\rho u, \rho u^2 + p, \rho uv, 0)^T, \quad F_E^y \; (\rho v, \rho uv, \rho v^2 + p, 0)^T,$$
$$F_{SI}^x \; \left(0, \frac{1 - \varepsilon^2}{\varepsilon^2} - p, 0, \frac{E + p}{\rho} (\rho u)\right)^T, \quad F_{SI}^y \; \left(0, 0, \frac{1 - \varepsilon^2}{\varepsilon^2} - p, \frac{E + p}{\rho} (\rho v)\right)^T.$$

We consider a rectangular domain discretized by a uniform Cartesian grid, with meshsize $\Delta x = \Delta y,$ and grid points $(x_i, y_j), \ i = 1, \ldots N_x, \ j = 1 \ldots N_y,$ located at cell centers. We use the subscript `$i,j$' to denote the solution point values at $(x_i, y_j)$, and `$i\pm1/2,j$' and `$i,j\pm1/2$' for the reconstructed numerical fluxes in approximating $x$- and $y$- derivatives respectively.

Below we first present two types of WENO spatial discretizations, i.e, a characteristic-wise
WENO and a component-wise WENO, for explicit and semi-implicit parts as specified in \eqref{3.11},
respectively.

1. **Characteristic-wise WENO $\nabla_{\text{CW}}$ with Lax-Friedrichs splitting for discretizing $\nabla \cdot F_E$.** For compressible hyperbolic systems with shocks, WENO reconstructions in the component-
   wise fashion may still lead to oscillations and a local characteristic decomposition will be
   needed \cite{72}. We let $F_{E,i,j}^+$ be the flux function at each grid point $(x_i, y_j)$. To approximate
   the $\partial_x F^x_E|_{x,y}$, we fix a $j$-index and perform a global Lax-Friedrichs splitting for the flux
terms, i.e.
$$F_{E,i,j}^x = F_{E,i,j}^{x,+} + F_{E,i,j}^{x,-}, \forall i$$
with
$$F_{E,i,j}^{x,+} = \frac{1}{2}(F_{E,i,j}^x + \Lambda U_{E,i,j}), \quad \Lambda = \max\{|u| + |v| + \min\{1, \frac{1}{\varepsilon}\} c_s\} \quad (3.32)$$
with $c_s = \sqrt{\gamma p/\rho}$ being the sound speed multiplied by $\varepsilon,$ and the max is taken over appro-
priate range of $u, v.$ Notice that such a choice of $\Lambda$ is the same as in our previous work \cite{8}.
We then project $\{F_{E,i,j}^{x,\pm}\}_{i=1}^{N_x}$ to local characteristics directions for the full Euler system in
the compressible regime (corresponding to $\varepsilon = 1$), perform WENO reconstruction of
fluxes there and then project the reconstructed fluxes back, to obtain the flux terms as
$$F_{E,i,j}^{x,\pm} = F_{E,i,j}^{x,+} + F_{E,i,j}^{x,-}.$$
Then
\[ \partial_x F_E |_{x_i, y_j} \approx \frac{1}{\Delta x} (\hat{F}_{E,i+\frac{1}{2},j} - \hat{F}_{E,i-\frac{1}{2},j}). \]

Similar procedure could be performed to approximate spatial derivatives in the y-direction.

We introduce the notation of \( \nabla_{CW} \) for the characteristic-wise WENO spatial discretization of \( F_E \).

2. A component-wise WENO \( \nabla_W \) with Lax-Friedrichs flux splitting for discretizing \( \nabla \cdot F_{SI} \). We apply a component-wise WENO reconstruction of fluxes for discretizing \( \nabla \cdot F_{SI} \) denoted as \( \nabla_W \cdot F_{SI} \). In particular, a Lax-Friedrichs flux splitting, followed by a component-wise WENO reconstruction is performed to obtain the numerical fluxes.

### 3.3.2 Flowchart and compact discretization of second order derivatives

With the introduction of characteristic-wise and component-wise WENO \( \nabla_{CW} \) and \( \nabla_W \), we summarize the flow chart of the SI-IMEX R-K time discretization (3.25) - (3.26), coupled with WENO spatial discretization, for solving all-Mach full Euler system. In this process, a compact high order discretization for second order spatial derivatives in (3.37) is applied.

1. Start from \( U^n \) at time \( t^n \), we first compute \( U_E^{(i)} \) from (3.25).

\[
\rho_E^{(i)} = \rho^n - \Delta t \sum_{j=1}^{i-1} \tilde{a}_{ij} \nabla_{CW} \cdot q_E^{(j)}, \quad (3.33a)
\]

\[
q_E^{(i)} = q^n - \Delta t \sum_{j=1}^{i-1} \tilde{a}_{ij} \left( \nabla_{CW} \cdot \left( \frac{q_E^{(j)} \otimes q_E^{(j)}}{\rho_E^{(j)}} + p_E^{(j)} I \right) \right) + (1 - \varepsilon^2) \frac{\nabla_W p_I^{(j)}}{\varepsilon^2}, \quad (3.33b)
\]

\[
E_E^{(i)} = E^n - \Delta t \sum_{j=1}^{i-1} \tilde{a}_{ij} \nabla_W \cdot \left( \tilde{H}^{(j)} q_I^{(j)} \right), \quad (3.33c)
\]

2. We compute \( \dot{U}^{(i)} \) in (3.25).

\[
\dot{\rho}^{(i)} = \rho^n - \Delta t \sum_{j=1}^{i-1} a_{ij} \nabla_{CW} \cdot q_E^{(j)}, \quad (3.34a)
\]

\[
\dot{q}^{(i)} = q^n - \Delta t \sum_{j=1}^{i-1} a_{ij} \left( \nabla_{CW} \cdot \left( \frac{q_E^{(j)} \otimes q_E^{(j)}}{\rho_E^{(j)}} + p_E^{(j)} I \right) \right) + (1 - \varepsilon^2) \frac{\nabla_W p_I^{(j)}}{\varepsilon^2}, \quad (3.34b)
\]

\[
\dot{E}^{(i)} = E^n - \Delta t \sum_{j=1}^{i-1} a_{ij} \nabla_W \cdot \left( \tilde{H}^{(j)} q_I^{(j)} \right), \quad (3.34c)
\]

with \( \tilde{H}^{(j)} = (E_E^{(j)} + p_E^{(j)})/\rho_E^{(j)} \).

3. Solve \( U_I^{(i)} \) from (3.25).

(a) In components, \( U_I^{(i)} \) satisfies

\[
\rho_I^{(i)} = \dot{\rho}^{(i)} - \Delta t a_{ii} \nabla_{CW} \cdot q_E^{(i)}, \quad (3.35a)
\]

\[
q_I^{(i)} = \dot{q}^{(i)} - \Delta t a_{ii} \left( \frac{1 - \varepsilon^2}{\varepsilon^2} \nabla p_I^{(i)} \right), \quad (3.35b)
\]

\[
E_I^{(i)} = \dot{E}^{(i)} - \Delta t a_{ii} \nabla \cdot (H_I q_I^{(i)}), \quad (3.35c)
\]

where

\[
\dot{q}^{(i)} = q^{(i)} - \Delta t a_{ii} \left( \nabla_{CW} \cdot \left( \frac{q_E^{(i)} \otimes q_E^{(i)}}{\rho_E^{(i)}} + p_E^{(i)} I \right) \right). \quad (3.36)
\]
In this section we prove the AP property of scheme (3.15). In particular, we prove that its
4.1 AP property
Asymptotic preserving (AP) and Asymptotically Accurate (AA) property
4.1 AP property
In this section we prove the AP property of scheme (3.15). In particular, we prove that its
\[ \frac{\rho_0^{n+1} u_0^{n+1} - \rho_0^n u_0^n}{\Delta t} + \nabla \cdot (\rho_0^n u_0^n \otimes u_0^n) + \nabla p_2^{n+1} = 0, \quad (4.43b) \]
\[ E_0^{n+1} = p_0^{n+1}/(\gamma - 1), \quad (4.43c) \]
\[ \frac{E_0^{n+1} - E_0^n}{\Delta t} + \nabla \cdot (\bar{H}_0^n (\rho_0^{n+1} u_0^{n+1})) = 0, \quad (4.43d) \]
with
\[ \bar{H}_0^n = \frac{p_0^n + E_0^n}{\rho_0^{n+1}} = \gamma - 1 \frac{p_0^n}{\rho_0^{n+1}}. \quad (4.44) \]

By (4.43c) and (4.44), (4.43d) is equivalent to
\[ \frac{p_0^{n+1} - p_0^n}{\Delta t} + \gamma \rho_0^n \nabla \cdot u_0^{n+1} = 0. \quad (4.45) \]

Note that (4.45) is the time discretization of the limiting equation for the pressure (2.5).

From (4.42), it follows that \( p_0^{n+1} \) is independent of space. Now, as in the continuous case, integrating (4.45) over a spatial domain \( \Omega \) and assuming some boundary conditions (for example, no-slip or periodic), we get
\[ \int \nabla \cdot \left( \frac{\rho_0^n}{\rho_0^{n+1}} (u_0^n \cdot \nabla) u_0^n \right) = -\int \nabla \cdot \left( \frac{1}{\rho_0^{n+1}} \nabla p_2^{n+1} \right), \]
which is a consistent discretization of Eq. (2.8) because \( \rho_0^n/\rho_0^{n+1} = 1 + \mathcal{O}(\Delta t) \).

Note that once it is established that \( \nabla \cdot u_0^{n+1} = 0 \), from the first equation of (2.4) it follows that if the initial density \( \rho_0^0 \) is constant, then it remains constant for any later time.

**Remark 4.2.** Note that in [16] the authors proposed a scheme similar to (3.15), but with a slight difference in the explicit treatment of the density in the energy equation, i.e.
\[ \frac{E^{n+1} - E^n}{\Delta t} + \nabla \cdot \left( \frac{E^n + p^n}{\rho^n} q^{n+1} \right) = 0. \]

Their scheme is AP, i.e. it is consistent with the limiting equations (2.4) in the incompressible regime. However, as \( \varepsilon \to 0 \), they prove that the divergence-free condition on the velocity is explicitly satisfied up to the order of the approximation with the CFL condition independent of the Mach-number \( \varepsilon \), i.e. \( \nabla \cdot u_0^{n+1} = \mathcal{O}(\Delta t) \) (see the Proposition in Section 4.2 in [16]). In our case, instead, scheme (3.15) has the correct discrete divergence-free condition for the leading order velocity \( u_0^{n+1} \), i.e. \( \nabla \cdot u_0^{n+1} = 0 \).

### 4.2 AA property

The AP property guarantees only the consistency of the scheme, but in general the AP property does not guarantee the high order accuracy of IMEX schemes in the limit for \( \varepsilon \ll 1 \), i.e. as \( \varepsilon \to 0 \) the order of accuracy may degrade. In what follows, we first formally state the definition of the AA property, and then we recognize that the SA condition is crucial to guarantee the AA property of our SI-IMEX R-K scheme. Similarly as the AP property, here we focus on the AA analysis on time discretizations, while keeping space continuous.
Definition 4.3. A semi-implicit temporal discretization for the Euler system (2.1) is said to be asymptotically accurate (AA), if it maintains its order of temporal accuracy for the limiting system (2.4) as \( \varepsilon \to 0 \).

Proposition 4.4. Consider an SI-IMEX R-K scheme (3.25)-(3.26) of order \( r \) applied to system (2.1) in a bounded domain \( \Omega \subset \mathbb{R} \) with zero Neumann condition. Assume that the implicit part of the IMEX R-K scheme is SA and that the initial conditions \( (\rho^0(x), \rho^0(x)u^0(x), p^0)^T \) are well-prepared in the form of (2.9). Let us denote by \( (\rho^1(x; \varepsilon), \rho^1(x; \varepsilon)u^1(x; \varepsilon), p^1(x; \varepsilon))^T \) the numerical solution after one time step. Then we have:

\[
\lim_{\varepsilon \to 0} \rho^1(x; \varepsilon) = p_* , \quad \lim_{\varepsilon \to 0} \nabla \cdot u^1(x; \varepsilon) = 0 ,
\]

with \( p_* \) a constant.

Furthermore, let \( \mathbf{V}_{inc}(x, t) = (\rho_{inc}(x, t), \rho_{inc}(x, t)u_{inc}(x, t), p_{inc}(x, t))^T \) be the exact solution of the incompressible Euler equations (2.6) with the same initial data. Then one has the following one-step error estimate

\[
\lim_{\varepsilon \to 0} \mathbf{V}^1(x; \varepsilon) = \mathbf{V}_{inc}(x, \Delta t) + \mathcal{O}(\Delta t^{r+1}),
\]

i.e., the scheme is AA.

**Proof.** We consider the first step from \( t^0 = 0 \) to \( t^1 = \Delta t \) for the SI-IMEX R-K scheme (3.25)-(3.26) of order \( r \) applied to system (2.1) with well-prepared initial data (4.41):

\[
\rho^0(x) = \rho_{inc}^0 + \varepsilon^2 \rho_{2}^0(x), \quad p^0(x) = p_* + \varepsilon^2 \rho_{2}^0(x), \quad u^0(x) = u_{inc}^0 + \mathcal{O}(\varepsilon),
\]

where \( \rho_{inc}^0 := \rho_{inc}(x, 0), u_{inc}^0 := u_{inc}(x, 0) \) and by well prepared assumption we have: \( \rho_{inc}(x, 0) := p_* \) constant independent of time and space, and \( \nabla \cdot u^0_{inc} = 0 \).

Now we consider a formal \( \varepsilon \)-expansion of the quantities \( U_I^{(i)} = (\rho_I^{(i)}, q_I^{(i)}, E_I^{(i)})^T \), and \( U_E^{(i)} = (\rho_E^{(i)}, q_E^{(i)}, E_E^{(i)})^T \) with \( q_I^{(i)} = \rho_{I}^{(i)} u_I^{(i)} \) and \( q_E^{(i)} = \rho_{E}^{(i)} u_E^{(i)} \), as an example for the density and pressure:

\[
\rho_{I}^{(i)} = \rho_{0,I}^{(i)} + \varepsilon^2 \rho_{2,I}^{(i)} + \ldots , \quad \rho_{E}^{(i)} = \rho_{0,E}^{(i)} + \varepsilon^2 \rho_{2,E}^{(i)} + \ldots ,
\]

\[
\rho_{I}^{(i)} = p_{0,I}^{(i)} + \varepsilon^2 p_{2,I}^{(i)} + \ldots , \quad \rho_{E}^{(i)} = p_{0,E}^{(i)} + \varepsilon^2 p_{2,E}^{(i)} + \ldots .
\]

In order to prove the theorem, we use the mathematical induction.

- **Asymptotic accuracy for the internal stages** \( i = 1, \ldots, s \).

Case \( i = 1 \) leads to the same AP analysis for the scheme (3.15) with \( \Delta t \) replaced by \( a_{11} \Delta t \). To prove the result for \( i > 1 \) onwards, we make use of the induction hypothesis, assuming the property holds for \( j \leq i - 1 \) and prove that it holds for \( j = i \). Then for \( j = 1, \ldots, i - 1 \) we have

\[
P_{0,E}^{(j)} = p_* , \quad E_{0,E}^{(j)} = \frac{P_*}{\gamma - 1} , \quad \nabla \cdot u_{0,I}^{(j)} = 0 .
\]

Now we insert the expansions (4.48) into the explicit step in (3.25), and we get for the energy equation:

\[
E_{0,E}^{(j)} = E_{inc}^0 - \Delta t \sum_{j=1}^{i-1} \tilde{a}_{ij} \nabla \cdot \left( \tilde{H}_{0,I}^{(j)} q_{0,I}^{(j)} \right) ,
\]

with \( E_{inc}^0 = p_*/(\gamma - 1) \) and for \( j = 1, \ldots, i - 1 \),

\[
\tilde{H}_{0,I}^{(j)} = \frac{E_{0,E}^{(j)} + p_{0,E}^{(j)}}{\rho_{0,I}^{(j)}} = \frac{\gamma}{\gamma - 1} p_* .
\]

Now by (4.49), (4.51) and \( E_{0,E}^{(i)} = p_{0,E}^{(i)}/(\gamma - 1) \), from (4.50) we obtain

\[
p_{0,E}^{(i)} = p_* - \Delta t \gamma \rho_{0,I}^{(i)} \sum_{j=1}^{i-1} \tilde{a}_{ij} \nabla \cdot u_{0,I}^{(j)} = p_* ,
\]

\[\text{14}\]
that is, \( p_0^{(i)} = p_* \) is constant. Then \( E_{0,E}^{(i)} = p_*/(\gamma - 1) \) is also constant for the stage \( i \).

From \((3.25)\), to \( O(1) \) we obtain for the density and momentum equations

\[
\rho_{0,E}^{(i)} = \rho_{inc}^0 - \Delta t \sum_{j=1}^{i-1} \tilde{a}_{ij} \nabla \cdot q_0^{(j)} \quad (4.53)
\]

and

\[
q_{0,E}^{(i)} = q_{inc}^0 - \Delta t \sum_{j=1}^{i-1} a_{ij} \left( \nabla \cdot \left( \rho_{0,E}^{(j)} u_{0,E}^{(j)} \otimes u_{0,E}^{(j)} \right) + \nabla p_{2,l}^{(j)} \right) \quad (4.54)
\]

with \( q_{inc}^0 = (\rho u)_{inc}^0 \) and \( \nabla p_{0,l}^{(j)} = 0 \) for \( j = 1, \ldots, i-1 \).

Similarly, inserting expansions \((4.48)\) into \((3.34b)\), up to \( O(1) \) we get for the intermediate explicit step \( \tilde{U}_0^{(i)} \) in \((3.25)\):

\[
q_0^{(i)} = q_{inc}^0 - \Delta t \sum_{j=1}^{i-1} a_{ij} \left( \nabla \cdot \left( \rho_{0,E}^{(j)} u_{0,E}^{(j)} \otimes u_{0,E}^{(j)} \right) + \nabla p_{2,l}^{(j)} \right) \quad (4.55)
\]

where from \((3.13)\) and \((4.49)\), it follows \( \nabla p_{E}^{(j)} = 0 \) for \( j = 1, \ldots, i-1 \). Furthermore, from \((3.34a)\) we have

\[
\rho_0^{(i)} = \rho_{inc}^0 - \Delta t \sum_{j=1}^{i-1} a_{ij} \nabla \cdot q_0^{(j)} \quad (4.56)
\]

and using \((4.51)\), we get

\[
\tilde{E}_{0}^{(i)} = E_{inc}^0 - \Delta t \sum_{j=1}^{i-1} a_{ij} \nabla \cdot (H_0^{(j)} q_0^{(j)}) = \frac{p_*}{\gamma - 1} - \frac{\gamma p_*}{\gamma - 1} \Delta t \sum_{j=1}^{i-1} a_{ij} \nabla \cdot u_0^{(j)} \quad (4.57)
\]

Thus, by \((4.49)\) we get from \((4.57)\)

\[
\tilde{E}_0^{(i)} = \frac{p_*}{\gamma - 1}. \quad (4.58)
\]

Now from \((3.24b)\) and \((4.58)\), it follows for the energy equation

\[
E_{0,l}^{(i)} = \tilde{E}_0^{(i)} - \Delta t a_{ii} \nabla \cdot (H_0^{(i)} q_0^{(i)}) = \frac{p_*}{\gamma - 1} - \Delta t a_{ii} \frac{\gamma p_*}{\gamma - 1} \nabla \cdot u_0^{(i)}
\]

Considering the EOS \((3.27b)\) to zeroth order in \( \varepsilon \), we get \( E_{0,l}^{(i)} = p_{0,l}^{(i)}/(\gamma - 1) \), and we obtain for the pressure

\[
p_{0,l}^{(i)} = p_* + \Delta t \gamma p_* a_{ii} \nabla \cdot u_0^{(i)} \quad (4.59a)
\]

Integrating it over spatial bounded domain \( \Omega \), and assuming some boundary conditions (for example, no-slip or periodic,) we first obtain \( p_{0,l}^{(i)} = p_* \) and by this we get \( \nabla \cdot u_0^{(i)} = 0 \) at the stage \( i \).

Finally, from \((3.24b)\), considering \((4.55)\) and \((4.56)\), we get for the density and momentum,

\[
\rho_{0,l}^{(i)} = \rho_{inc}^0 - \Delta t \sum_{j=1}^{i} a_{ij} \nabla \cdot q_{0,E}^{(j)} \quad (4.59a)
\]

\[
q_{0,l}^{(i)} = q_{inc}^0 - \Delta t \sum_{j=1}^{i} a_{ij} \left( \nabla \cdot \left( \rho_{0,E}^{(j)} u_{0,E}^{(j)} \otimes u_{0,E}^{(j)} \right) + \nabla p_{2,l}^{(j)} \right) \quad (4.59b)
\]

where from \((3.13)\) and \( p_{0,E}^{(i)} = p_* \) it follows in the equation of the momentum \( \nabla p_{E}^{(i)} = 0 \) for \( i \).
Then equations (4.53), (4.54), (4.59a), (4.59b), with constant limiting pressure, i.e. \( p_{0,k}^{(i)} = p_{0,i}^{(i)} = p_+ \) and, the divergence free leading order velocity, i.e., \( \nabla \cdot \mathbf{u}_0^{(i)} = 0 \), provide the discretization of system (2.6) for the internal stage \( i \) of SI-IMEX R-K scheme. This shows that in the limit \( \varepsilon \to 0 \), the scheme becomes the same SI-IMEX RK time-discrete scheme for the incompressible Euler equations (2.6).

- **Asymptotic accuracy for the numerical solution.**

Assuming that SI-IMEX R-K scheme (3.22) is SA, then the numerical solution coincides with the last internal stage \( s \), and then by setting \( i = s \), we get

\[
p_0^{(i)} = p_{0,i}^{(i)} = p_+, \quad \nabla \cdot \mathbf{u}_0^{(i)} = \nabla \cdot \mathbf{u}_0^{(s)} = 0,
\]

i.e., we have (4.46).

Now if we denote by \( \mathbf{V}_{\text{inc}}(\mathbf{x}, t) = (\rho_{\text{inc}}(\mathbf{x}, t), \rho_{\text{inc}}(\mathbf{x}, t), \mathbf{u}_{\text{inc}}(\mathbf{x}, t), p_{\text{inc}}(\mathbf{x}, t))^T \) the exact solutions of (2.6), with initial data \( \mathbf{V}_{\text{inc}}(\mathbf{x}, 0) = (\rho^0(\mathbf{x}), \rho^0(\mathbf{x}), \mathbf{u}^0(\mathbf{x}), p^0)^T \), from equations (4.53), (4.54), (4.59b) and (4.59a), with (4.60), one gets in the limit case \( \varepsilon = 0 \), a SI-IMEX R-K scheme of order \( r \) for the numerical solutions of equations (2.6), that is, the SI-IMEX R-K scheme (3.25)-(3.26) of order \( r \) is asymptotically accurate (AA), and the conclusion (4.47) is obtained.

## 5 Numerical Tests

Through an extensive set of 1D and 2D numerical tests, we will show that our scheme is uniformly stable, effective and can capture the correct asymptotic limit. We use the 3rd order SI-IMEX(4,4,3) scheme in time (3.30), 4th order compact central difference discretization for 2nd order derivatives in the elliptic equation (3.37), and 5th order finite difference WENO reconstruction in space for both \( \nabla W \) and \( \nabla CW \) in Section 3.3. Overall the scheme is 4th order in space and 3rd order in time, denoted as “S4T3”. On the other hand, an “S2T2” scheme refers to using a 2nd order TVB reconstruction with the parameter \( M = 1 \) instead of a 5th order WENO reconstruction in the S4T3 scheme, and a 2nd order SI-IMEX(3,3,2) scheme in time (3.31). Reference solutions are computed by a 5th order finite difference WENO scheme with 3rd order explicit R-K time discretization [42], denoted as “WENO5RK3”. For simplicity, we all take \( \gamma = 1.4 \) with an ideal EOS. The time step is \( \Delta t = \text{CFL} \Delta x / \Lambda \), where \( \Lambda = \max_x (|u| + \min(1/\varepsilon, 1) c_s) \) in 1D, and \( \Lambda = \max_{x,y} (|u| + |v| + \min(1/\varepsilon, 1) c_s) \) in 2D respectively. \( c_s = \sqrt{\gamma p/\rho} \) is the scaled sound speed. We take CFL = 0.25 for all tests.

**Example 5.1.** (Two colliding acoustic pulses [34, 39]) This problem is defined on the domain \(-L \leq x \leq L = 2/\varepsilon\) with periodic boundary condition and initial data

\[
\begin{align*}
\rho(x, 0) &= \rho_0 + \frac{1}{2} \varepsilon \rho_1 (1 - \cos (2\pi x/L)), \quad \rho_0 = 0.955, \quad \rho_1 = 2.0; \\
u(x, 0) &= \frac{1}{2} u_0 \text{sign}(x) (1 - \cos (2\pi x/L)), \quad u_0 = 2\sqrt{\gamma}; \\
p(x, 0) &= \rho_0 + \frac{1}{2} \varepsilon^2 \rho_1 (1 - \cos (2\pi x/L)), \quad \rho_0 = 1.0, \quad \rho_1 = 2\gamma.
\end{align*}
\]

We first test the order of accuracy for our scheme. Due to \( u(x, 0) \) in (5.1) is not smooth enough, in order to observe more than 2nd order accuracy, we modify it as

\[
u(x, 0) = u_0 \sin (2\pi x/L) (1 - \cos (2\pi x/L)) / 2.
\]

Others are the same as in (5.1). We take \( \varepsilon = 10/11 \) to avoid order reduction from the high order IMEX time discretization. We take mesh sizes with \( N_k = 2^k \cdot N_0 \), where \( k = 0, 1, 2, 3 \) and \( N_0 = 40 \). Reference solutions are computed with \( N = 2560 \). The errors are computed by comparing the numerical solutions for the pressure \( p_E \) to its reference solution. In Table 5.1 we show the errors and orders at time \( t = 0.1 \). The order of convergence is between 4 and 5, due to the dominance of spatial errors.

Then we take \( \varepsilon = 1/11 \) with initial condition (5.1) and compute the solution up to \( T = 1.63 \) by both “S2T2” and “S4T3” schemes. A reference solution is computed with \( N = 2200 \). In
Table 5.1: Convergence test for the two colliding acoustic pulses problem with initial condition (5.1), and the velocity is replaced by (5.2). $t = 0.1, \varepsilon = 10/11$.

| $N$ | $40$ | $80$ | $160$ | $320$ |
|-----|------|------|-------|-------|
| $L^1$ error | $1.62E-02$ | $9.97E-04$ | $3.54E-05$ | $1.34E-06$ |
| order | $–$ | $4.02$ | $4.82$ | $4.72$ |

Figure 5.1: Two colliding acoustic pulses with initial condition (5.1). $t = 1.63$.

Fig. 5.1 we compare the reference solution with the numerical ones obtained with $N = 22$ grid points at time $t = 1.63$. We can see that the results of the “S4T3” scheme on the very coarse mesh match the reference solutions better than the “S2T2” scheme.

Example 5.2. (1D shock tube problem.) In this example, we consider two 1D shock tube problems in the compressible regime when the Mach number is of $O(1)$. We take the initial data, one is the Sod problem, where

\[
(\rho, u, p) = (1, 0, 1), \text{ if } x < 0.5; \quad (\rho, u, p) = (0.125, 0, 0.1), \text{ otherwise;}
\]

another is the Lax problem, where

\[
(\rho, u, p) = (0.445, 0.698, 3.528), \text{ if } x < 0.5; \quad (\rho, u, p) = (0.5, 0, 0.571), \text{ otherwise,}
\]

both with $\varepsilon = 1$ on the domain $x \in [0, 1]$. Reflective boundary conditions are considered and we take $N = 50$. We compute the numerical solution by both “S2T2” and “S4T3” schemes. The results are shown in Fig. 5.2 and compared to the exact solutions. For both the Sod and Lax shock tube problems, the results match the exact solutions very well, which show that our scheme in the moderate Mach regime ($\varepsilon$ of order 1) can capture strong discontinuities without any observable numerical oscillations.

Example 5.3. (2D Convergence test.) We take the initial data

\[
\begin{align*}
\rho(x, y, 0) &= 1 + \varepsilon^2 \sin^2(2\pi(x + y)), \\
\rho(x, y, 0) u(x, y, 0) &= \sin(2\pi(x - y)) + \varepsilon^2 \sin(2\pi(x + y)), \\
\rho(x, y, 0) v(x, y, 0) &= \sin(2\pi(x - y)) + \varepsilon^2 \cos(2\pi(x + y)),
\end{align*}
\]

on the domain $\Omega = [0, 1]^2$ with periodic boundary conditions. Initially we take $p = \rho^\gamma$. We choose $N = N_x = N_y$ and refine the mesh size by $N_k = 2^k \cdot N_0$, for $k = 0, 1, 2$, with $N_0 = 32$. The numerical errors are computed by comparing the numerical solutions of momentum $q_2$ to the reference solution, which is computed by the “S4T3” scheme on the mesh $N_x = N_y = 512$. In Table 5.2 we show the errors and orders at time $t = 0.02$. Around 4th order for $\varepsilon = 1$ and 5th order for $\varepsilon = 10^{-6}$ are observed. For the intermediate value of $\varepsilon = 10^{-2}$, order reduction is observed. In Fig. 5.3 we display the orders versus $\varepsilon$ for $\varepsilon \in [10^{-6}, 1]$, where the order is computed by comparing the errors on the mesh $64 \times 64$ and $128 \times 128$. Order reduction for intermediate $\varepsilon$’s is observed.
Figure 5.2: Example 5.2. 1D shock tube problem for $\varepsilon = 1$. Top: the Sod problem at $t = 0.2$. Bottom: the Lax problem at $t = 0.16$. Mesh grid: $N = 50$. The solid lines are the exact solutions.

Table 5.2: Example 5.3. Convergence test for 2D full Euler equations with initial condition (5.5) at $t = 0.02$. Errors are computed by comparison with a reference solution.

| $\varepsilon$ | $L^1$ error order | $L^1$ error order | $L^1$ error order |
|---------------|--------------------|--------------------|--------------------|
| $\varepsilon = 1$ | 4.64e-03 | $2.45e-03$ | 7.26e-05 |
| $\varepsilon = 10^{-2}$ | 2.68e-03 | 1.79e-06 | 5.34 |
| $\varepsilon = 10^{-6}$ | 1.43e-03 | 4.81e-08 | 5.22 |

Figure 5.3: Example 5.3. 2D convergence test for the “S4T3” scheme. Convergence orders versus $\varepsilon$’s for $\varepsilon \in [10^{-6}, 1]$. As the space error dominates, the scheme is observed to have 5th order convergence for small and around 4th order for large values of $\varepsilon$. Order degradation is observed for intermediate values of the Mach number.
Example 5.4. (2D Riemann problem.) This is a 2D Riemann problem in the high Mach regime. We take \( \varepsilon = 1 \) and \( \Omega = [-1, 1]^2 \). The initial data are defined in four quadrants, which are modified from Configuration 3 in [35] with four shocks

\[
(\rho, u, v, p) = \begin{cases}
(1.5, 0, 0, 1.5), & x \geq 0.8, \ y \geq 0.8; \\
(0.5323, 1.206, 0, 0.3)), & x < 0.8, \ y \geq 0.8; \\
(0.138, 1.206, 1.206, 0.029), & x < 0.8, \ y < 0.8; \\
(0.5323, 0, 1.206, 0.3), & x \geq 0.8, \ y < 0.8.
\end{cases}
\] (5.6)

The second one is the Configuration 5 in [35] with four contact discontinuities, where the initial data are

\[
(\rho, u, v, p) = \begin{cases}
(1, -0.75, -0.5, 1), & x \geq 0.5, \ y \geq 0.5; \\
(2, -0.75, 0.5, 1), & x < 0.5, \ y \geq 0.5; \\
(1, 0.75, 0.5, 1), & x < 0.5, \ y < 0.5; \\
(3, 0.75, -0.5, 1), & x \geq 0.5, \ y < 0.5.
\end{cases}
\] (5.7)

We take mesh size \( N_x \times N_y = 400 \times 400 \). For this example, four different approaches are compared to the reference solution. The first one is our main approach, which is splitting by taking \( \alpha = 1 \) in (3.11), using both spatial discretizations \( \nabla_{CW} \) and \( \nabla_W \) described in Section 3.3 (“A1”); another one uses the same splitting, but replaces \( \nabla_{CW} \) all by \( \nabla_W \) (“A2”); the third one is no splitting, namely, we take \( \alpha = 0 \) in (3.11) and only \( \nabla_W \) is used (“A3”); the last one is the “S2T2” scheme using the same approach as “A1”. In Fig. 5.4 we show the surface plots of the density at \( T = 0.8 \) for the initial data (5.6). We can see that the solution of A1 is the closest to the reference solution and no obvious oscillations are observed. For the other two approaches A2 and A3, the solutions do not perform well, numerical oscillations can be clearly seen in the middle region. The result of the 2nd order “S2T2” scheme is close to “A1”, but it has poorer resolutions. We also show the cutting plots along two different lines. A1 approach is observed to perform better than the A2 and A3 approaches, and “S2T2” is in between but a little closer to “A1”, which show the importance of characteristic reconstructions. In Fig. 5.5, we present same results for the 2D Riemann initial data (5.7) at \( T = 0.23 \). Similar observations can be made.

Example 5.5. (Gresho vortex [39] [8].) This is the time-dependent rotational Gresho vortex problem for the full Euler system. Initially a vortex is centered at \( (x_0, y_0) = (0.5, 0.5) \) with radius \( R = 0.4 \) in the domain \([-0.1, 0.1]^2\). The initial background state is set as: \( \rho_\infty = 1, u_\infty = (u_\infty, 0), p_\infty = 1, c_\infty = \sqrt{\gamma p_\infty/\rho_\infty} = \sqrt{\gamma} \). The transverse velocity for the vortex is given by

\[
u_\theta(r) = \begin{cases}
2r/R, & \text{if } 0 \leq r < R/2, \\
2(1 - r/R), & \text{if } R/2 \leq r < R, \\
0, & \text{if } r \geq R,
\end{cases}
\] (5.8)

and the corresponding velocity components are

\[
u(x, y, 0) = u_\infty - \frac{y - y_0}{r} \nu_\theta(r), \ \nu(x, y, 0) = \frac{x - x_0}{r} \nu_\theta(r).
\]

The centrifugal force is balanced by the pressure gradient, so the (scaled) pressure is given by

\[
p(r) = p_\infty + \varepsilon^2 \begin{cases}
2(r/R)^2 + 2 - \log 16, & \text{if } 0 \leq r < R/2, \\
2(r/R)^2 - 4(2r/R + \log(r/R)) + 6, & \text{if } R/2 \leq r < R, \\
0, & \text{if } r \geq R,
\end{cases}
\] (5.9)

where \( r = \sqrt{(x-0.5)^2 + (y-0.5)^2} \). Periodic boundary conditions on both directions are used and the mesh is \( N_x \times N_y = 100 \times 100 \). The background velocity is \( u_\infty = 0.1 \) moving in the \( x \)-direction, and we take \( \varepsilon = 10^{-1}, 10^{-2}, 10^{-6} \). The rotation period is \( 2\pi/\omega = R\pi \) if \( r \leq R/2 \). We take \( T = R\pi \) as one rotating period.

We define the ratio between the local and the maximum Mach number as

\[
M_{\text{ratio}} = \sqrt{[(u - u_\infty)^2 + v^2]/(\gamma p/\rho)}.
\] (5.10)
Figure 5.4: Example 5.4. Surface and cut plots of the density for 2D Riemann problem (5.6) at \( T = 0.8 \). Mesh grid: 400 \( \times \) 400. Top left: reference solution; top right: the approach A1, splitting with characteristic-wise reconstruction \( \nabla_{CW} \); middle left: the approach A2, splitting with only component-wise reconstruction \( \nabla_W \); middle middle: the approach A3, no splitting; middle right: S2T2. Bottom are 1D cuts of these solutions.

In Fig. 5.6 (top left), we show the surface plot of \( M_{\text{ratio}} \) for the initial condition with \( \varepsilon = 10^{-2} \), which is very similar for other \( \varepsilon \)'s. As time evolves, the solution will rotate while moving in the \( x \)-direction, but its shape will be kept. However, numerically the shape will be damped due to numerical viscosity. This is a standard example to check whether the numerical viscosity greatly depends on the parameter \( \varepsilon \) or not. For better illustration, we show the cutting plots along \( x = 0.5 \) at two different times: 1 period and 2 periods, for both schemes “S4T3” and “S2T2”, and compare them to the corresponding initial shapes, for \( \varepsilon = 10^{-1}, 10^{-2}, 10^{-6} \) respectively. In these plots, the vortex are shifted to the center by \(-u_\infty t\) periodically. Two meshes are used: \( 100 \times 100 \) and \( 200 \times 200 \). We can see that the shapes are preserved relatively well for both “S4T3” and “S2T2” schemes, and the results of “S4T3” are a little better than those of “S2T2”.

In Fig. 5.6, we also show the time evolution of the averaged kinetic energy, which is defined as

\[
\text{kinetic energy} = \sum_{i,j} \left[ (u(x_i, y_j, t) - u_\infty)^2 + v(x_i, y_j, t)^2 \right] / N_x N_y. \quad (5.11)
\]

We can see the conservation of kinetic energy is well maintained. For a coarse mesh \( 100 \times 100 \), the high order scheme “S4T3” preserves the kinetic energy clearly better than “S2T2”. Refining the mesh can greatly improve the conservation of the kinetic energy, and the differences between these two methods are reduced especially for small \( \varepsilon \)'s.

**Example 5.6.** (Incompressible flow.) Finally we consider two problems in the incompressible flow regime by taking \( \varepsilon = 10^{-6} \). One is the shear flow problem on \([0, 2\pi]\) with \( v(x, y, 0) = \delta \cos(x) \), \( u(x, y, 0) = \begin{cases} \tanh((y - \frac{x}{2})/\rho), & \text{if } y \leq \pi, \\ \tanh((\frac{3\pi}{2} - y)/\rho), & \text{if } y > \pi. \end{cases} \) (5.12)
Figure 5.5: Example 5.4. Surface plots of the density for 2D Riemann problem (5.7) at $T = 0.23$. Mesh grid: $400 \times 400$. Top left: reference solution; top right: the approach A1, splitting with characteristic-wise reconstruction $\nabla_{CW}$; middle left: the approach A2, splitting with only component-wise reconstruction $\nabla_{W}$; middle middle: the approach A3, no splitting; middle right: S2T2. Bottom are 1D cuts of these solutions.

The other is the Kelvin-Helmholtz instability problem \cite{17} on $[0, 4\pi] \times [0, 2\pi]$ with

$$u(x, y, 0) = \cos(y), \quad v(x, y, 0) = 0.03 \sin(0.5x).$$  \hspace{1cm} (5.13)

The initial density and pressure for both cases are taken to be 1. For the shear flow problem, we run the solution up to $T = 6$ on a mesh grid $256 \times 256$, while $T = 40$ for the Kelvin-Helmholtz instability problem on the mesh grid $N_x \times N_y = 256 \times 128$. The vorticity $\omega = v_x - u_y$ for both cases are shown in Fig. 5.7, where $v_x$ and $u_y$ are discretized by the 4th order central difference. We observe that it is comparable to the results for the isentropic case as in \cite{8}.

We also show the time evolution of the divergence error $u_x + v_y$ for the velocity in Fig. 5.7. The divergence is computed by a 5th order finite difference WENO reconstruction with zero viscosity, which mimics what we have done in the numerical scheme. We also compare it with the linear 4th order central difference discretization. For both cases, the divergence error is increasing with time. When very fine structures are no longer supported by the mesh, the divergence error suffers from a sudden increase. We would remark that when the flow is incompressible or weakly incompressible, without discontinuities in the initial condition, high order linear reconstructions would perform better than WENO reconstructions in preserving the divergence and in resolving solution structures.

6 Conclusion

In this paper we present a high-order semi-implicit IMEX RK WENO scheme for the full compressible Euler equations in the case of all-Mach flows. We combine the semi-implicit IMEX RK discretization in time with high order finite difference WENO space discretizations. The EOS is treated in a semi-implicit manner, therefore requiring the solution of linearized elliptic systems.
Figure 5.6: Example 5.5, Gresho vortex problem. Top left: $M_{\text{ratio}}$ in (5.10) at $T = R\pi$ on the mesh grid $100 \times 100$. Top middle: time evolution of the kinetic energy (5.11) relative to its initial value on the mesh grid $100 \times 100$. Top right: time evolution of the kinetic energy (5.11) relative to its initial value on the mesh grid $200 \times 200$. Middle and bottom: cuts along $x = 0.5$ at three different times, initial ($t = 0$), 1 period ($t = 1p$), 2 periods ($t = 2p$). The results are shifted to the center by $-u_\infty t$ periodically. From left to right: $\varepsilon = 10^{-1}$, $\varepsilon = 10^{-2}$, $\varepsilon = 10^{-6}$.

Middle: mesh $100 \times 100$; bottom: mesh $200 \times 200$.

at each time step. Characteristic reconstructions are proposed in the semi-implicit framework with a fixed splitting for the pressure. The scheme is proven to be asymptotic preserving and asymptotically accurate in the incompressible limit. Numerical tests have demonstrated the efficiency and effectiveness of our proposed approach.
