Abstract

Objective: The aim of this study was to determine the biological effects of natural dietary intake of vitamin K as phylloquinone (K₁) and menaquinone-4 (MK-4) and a control diet also containing menadione (K₃) on levels of K₁ and total MK-4 (menaquinone-4) and menaquinone-4-2,3-epoxide (MK-4O) in liver and pancreas, and on femur bending resistance in a fast-growing animal model.

Design: Chickens were fed four wheat-based diets from day 11 to day 22 after hatching. The diets contained different combinations of fat sources: rapeseed oil, animal rendered fat, soybean oil and hydrogenated soybean oil. Concentration of K₁ in the three experimental diets was 120 ng/g whereas MK-4 levels were 23, 52 and 63 ng/g respectively. The control diet contained 157 ng K₁/g, 75 ng MK-4/g and 2.250 ng K₃/g.

Results: Growth rates and femur strength confirmed adequate supply of nutrients and vitamin K in the test groups. There were no significant differences in femur bending resistance among the test groups, but these were higher than the control. K₁, MK-4 and MK-4O were found in liver. In pancreas, mainly MK-4O was found with small amounts of MK-4, but none had content of K₁. In the test groups the hepatic levels of MK-4 and MK-4O reflected the dietary intake of MK-4.

Conclusion: The chickens were in good health with good bone resistance without supplements of K₃ in the feed, but at least a natural content of 23 ng MK-4/g feed. Liver and pancreas appears to use MK-4 in different ways.

Keywords: Menaquinone-4; diet; liver; pancreas; chicken
The present study was designed to investigate how ordinary dietary doses of vitamin K would influence tissue accumulation of K₁ and MK-4. Care was taken to vary only the dietary concentration of MK-4 together with an adequate and stable concentration of K₁, and in an identical feed matrix so as to limit any feed-induced variations in bioavailability. For comparison regarding the adequacy of the feeds a control group receiving the standard chicken feed containing additional K₃ was included.

Vitamin K–dependent carboxylation of bone matrix proteins is regarded as important for bone matrix calcification (14). Bone strength was measured to investigate whether our modest variations in vitamin K content could be detected in this system.

**Methods**

**Chickens**

Fifty-seven newly hatched male chickens (Samvirke kylling Norway, Ross 308) from the same hatching farm were used in this experiment conducted at The Norwegian University of Life Sciences. Animal treatment and animal facilities all complied with the Guide for the Care and Use of Laboratory Animals (15). The experimental animal research followed internationally recognized guidelines. All animals were cared for according to Norwegian laws and regulations for experiments with live animals (The Animal Protection Act of December 20th, 1974, and the Animal Protection Ordinance Concerning Experiments with Animals of January 15th, 1996).

**Experimental design**

The chickens were randomly assigned into one of four dietary 22 day treatments. During the first 10 days each group of 14 to 15 animals were kept in deep littered pens; 75 cm × 150 cm. At day 10 they were weighed and individually placed in wire-floored metabolism cages up until day 22. The chickens were raised in an environmentally controlled room. The room temperature was maintained at 32°C from days 0–3, then gradually reduced by 0.5°C per day until day 22. They were exposed to 23 h light and 1 h dark photoperiod days 0–7, the next 2 weeks they were exposed to 2 × 4 h dark; the dark periods were between 17–21 h and 00–04 h. The chickens had free access to feed and water. Water troughs and wire-floors were cleaned daily, with small possibility of coprophagy. Feed intake and body weight were registered day 11 to day 22. None of the birds were sick or died during the feeding period.

**Sampling**

At day 22 the chickens were weighed, killed by carbon dioxide narcosis and dissected immediately after death. Organs and limbs were packed in aluminum foil, frozen in liquid nitrogen and stored at −20°C before being analyzed.

**Vitamin K in diets**

Rapeseed oil was purchased from AFB, Askim, Norway and contained 60% oleic acid, 20% linoleic acid and 10% alpha linolenic acid. Rendered animal fat (RAF) was obtained locally and contained fat from ruminants (about 70%) and pigs (about 30%). The composition of RAF was (by weight): 26% palmitic acid, 18% stearic acid, 36% oleic acid and 8% linoleic acid. Fully hydrogenated soybean oil (HSO), refined to remove K₁ and ineffective dihydrophylloquinone together with trans-fatty acids, were purchased from AAK (Aarhus-Karlshamn) Sweden AB. The level of K₁ in HSO was less than 10% of the original amount in untreated soybean oil. Dihydrophylloquinone was not detected in the oils.

All four feeds were wheat based and composed according to guidelines adjusted to the requirements of chickens (Table 1). The feeds were manufactured at ForTek, Aas, Norway, with a matrix type 2.5 mm × 46 mm at a rate of 600 kg/h. They had the same basic composition with regard to protein, carbohydrates, minerals and vitamins except vitamin K. All diets contained lipid in the form of oils and solid fats. The control (CTR) feed group contained vitamin K₁ from rapeseed oil and soy bean oil; MK-4 from RAF and added K₁. The experimental feeds contained natural levels of K₁ and MK-4 from vitamin K.

| Ingredients                  | CTR  | MIX  | RAF  | HSO  |
|------------------------------|------|------|------|------|
| Wheat (%)                    | 60   | 60   | 60   | 60   |
| Soybean meal (%)             | 20   | 20   | 20   | 20   |
| Fish meal (%)                | 3    | 3    | 3    | 3    |
| Rapeseed oil (%)             | 5    | 0    | 0    | 0    |
| Animal Rendered fat (%)      | 5    | 4    | 8    | 0    |
| Soybean oil (%)              | 0    | 2    | 2    | 0    |
| Hydrogenated soybean oil (%) | 0    | 4    | 0    | 8    |
| Mineral mixture* (%)         | 0.15 | 0.15 | 0.15 | 0.15 |
| Vitamin mixture* (%)         | 0.08 | 0.08 | 0.08 | 0.08 |
| MK-4 (ng/g feed)             | 75.3 | 62.5 | 51.6 | 22.6 |
| K₁ (ng/g feed)               | 157.2| 120.4| 119.8| 119.1|
| K₃ (ng/g feed)               | 2,250| –    | –    | –    |

Notes: All feeds contained Monocalcium phosphate 2%; Ground limestone 1.85%; NaCl 0.25%; DL-Methionine 0.4%; L-lysine 0.3%; L-Threonine 0.1%; Choline chloride 0.13% and MgO 6.57 × 10⁻²%. *Vitamin and mineral mixture provided the following per kg feed: retinyl acetate, 2.7 mg; cholecalciferol, 0.07 mg; DL-alpha tocopheryl acetate, 38 mg; pyridoxine, 3.4 mg; riboflavin, 9 mg; Ca-pantothenate, 12.5 mg; biotin, 0.19 mg; thiamine, 1.9 mg; niacin, 37.5 mg; cobalamin, 0.02 mg; folic acid, 1.5 mg; choline chloride, 500 mg; zinc, 75 mg; iron, 95 mg; cupper, 10 mg; iodine, 0.6 mg; selenium, 0.43 mg.
RAF, fully HSO or a mixture of animal rendered fat and fully HSO (MIX). The experimental diets contained 2% natural soybean oil to provide a small supplement of $K_1$ (Table 1). $K_1$ content of the control diet was 32% higher than the experimental feeds. The experimental feeds had MK-4 levels from 20 to 50% of the $K_1$ level.

**Vitamin K analysis**

Vitamin K in liver, pancreas and feeds were analyzed by HPLC using a C-18 reversed phase column and fluorometric detection after postcolumn electrochemical reduction according to Thijssen et al. (16).

**Testing of bone strength**

The right femur was thawed gently and dissected free of muscle. Bending resistance was tested in a TA-XT2 texture analyzer from Stable Micro Systems, Godalming, Surrey, UK (www.stablemicrosystems.com). Probe velocity was at 0.1 mm/s, and the distance between the supports was 32.5 mm. Load-versus-time curves were generated and analyzed by means of Texture Expert Exceed v2.64 software. Bending resistance was calculated from the initial linear segment of the graphs and expressed as N/mm.

**Statistical analyses**

Statistical calculations (linear regression) on the effect of the four dietary treatments were performed by SPSS 15.0 IBM SPSS, Statistical Analyses Software (http://www.spss.com/), using comparative means by one-way ANOVA and Bonferroni test for assumption of equal variances.

**Results**

**Chicken growth**

Weight at day 11 and 22 showed that the chickens in the experimental groups ate slightly more and the RAF and HSO group grew significantly faster than the MIX and CTR groups indicating a satisfactory nutritional status (Table 2). Total amount of MK-4 eaten by the chicken was significantly different, being highest in the CTR group and lowest in the HSO group, while for $K_1$ no difference between experimental group but significantly higher in the control group (Table 2).

**Vitamin K in liver and pancreas**

Pancreas had higher vitamin K concentration than liver (Table 3). In liver, MK-4 was the most abundant vitamer, while in pancreas MK-4O was the main vitamer. $K_1$ was not detected in pancreas (Table 3). The association between the amounts of MK-4 consumed and MK-4 in liver was statistically significant.

**Table 2. Information on feed and weight of the chicken from day 11 to day 22**

|          | CTR | MIX | RAF | HSO |
|----------|-----|-----|-----|-----|
| n (number of chickens) | 15  | 14  | 14  | 14  |
| Chicken weight day 11 (g) | 268 (18)$^{a,c,d}$ | 243 (13)$^{b,d}$ | 274 (16)$^{a,c}$ | 256 (13)$^{b,d}$ |
| Chicken weight day 22 (g) | 800 (84)$^a$ | 827 (48)$^b$ | 939 (68)$^b$ | 936 (63)$^b$ |
| Liver weight (g) | 28 (3)$^a$ | 27 (3)$^b$ | 30 (3)$^b$ | 30 (5)$^b$ |
| Feed intake (g) | 680 (72)$^a$ | 701 (41)$^{a,b}$ | 746 (51)$^b$ | 766 (64)$^b$ |
| $K_1$ intake (ug) | 107 (11)$^a$ | 84 (5)$^b$ | 90 (6)$^b$ | 92 (8)$^b$ |
| MK-4 intake (ug) | 51 (5)$^a$ | 44 (3)$^b$ | 38 (3)$^b$ | 17 (1)$^d$ |

Notes: Values are means and SD.

**Bone strength**

The bending resistance of the femur was slightly higher in the experimental groups than in the control group, with no difference between the experimental groups (Table 3).

**Table 3. Levels of vitamin K in liver and pancreas and femur bending resistance**

|          | CTR | MIX | RAF | HSO |
|----------|-----|-----|-----|-----|
| Liver $K_1$ (ng/g) | 47 (11)$^a$ | 28 (11)$^b$ | 35 (16)$^a$ | 26 (12)$^b$ |
| MK-4 (ng/g) | 425 (66)$^a$ | 238 (56)$^b$ | 105 (22)$^a$ | 59 (14)$^b$ |
| MK-4O (ng/g) | 104 (25)$^a$ | 80 (25)$^b$ | 38 (16)$^a$ | 23 (16)$^b$ |
| MK-4/(MK-4 + MK-4O)% | 75 (9) | 66 (11) | 64 (14) | 63 (20) |
| Pancreas MK-4O (ng/g) | 1,158 (617)$^a$ | 522 (351)$^a$ | 316 (186)$^a$ | 118 (61)$^a$ |
| MK-4 (ng/g) | 59 (86) | 32 (49) | 7 (9) | 11 (9) |
| MK-4/(MK-4 + MK-4O)% | 5 (13) | 6 (13) | 2 (4) | 9 (9) |

Discussion
It has long been known that MK-4 is being synthesized in tissues of animals. Our experimental model seems to suggest that conversion of K₁ to MK-4 did not take place in the presence of adequate levels of MK-4 in the feed, not even in the feed group with the lowest level of MK-4 (HSO). In the test groups the hepatic levels of MK-4 and MK-4O reflected the dietary intake of MK-4. Recently, a specific enzyme that converts K₁ to MK-4 has been discovered and described (10). The production capacity of this enzyme has not been compared with or distinguished from the menadione prenylation system (5), so published evidence is as yet insufficient for a full quantitative picture of the various sources and pathways of synthesis in normally fed animals. MK-4O was in a different way dependent on the vitamin in the feed. The control group had the highest MK-4O levels in pancreas. This could be related to the supplementary K₃ given to that group only. Liver and pancreas appears to use MK-4 in different ways; in liver 1/3 of MK-4 is converted to MK-4O while in pancreas almost all is as MK-4O. The content of K₁ in liver was higher in the control group. The feed for this group contained more K₁ and K₃ was added.

Conclusion
The chickens were in good health with good bone resistance without supplements of K₃ in the feed but at least a natural content of 23 ng MK-4/g feed. Liver and pancreas appears to use MK-4 in different ways.
